9th INTERNATIONAL WORKSHOP ON ACCELERATOR ALIGNMENT, IWAA-2006 Stanford Linear Accelerator Center, September 25-29, 2006.

Outlook

- Requirements for the ILC Tunnel Survey and Alignment
- Principles of the LiCAS-RTRS¹ train operation
- Software used in the simulation:
 - Error propagation
 - LiCAS Ray-Tracer and Reconstruction
 - LiCAS Monte Carlo
- Simulation of single train stop (~ 20 m)
- Train operation along the accelerator tunnel ($\sim 100\,m$)
- Random walk model for the error propagation (extrapolation to $\sim 600\,m$)
- Conclusions

¹Rapid Tunnel Reference Surveyor

Alignment and survey: basic requirements

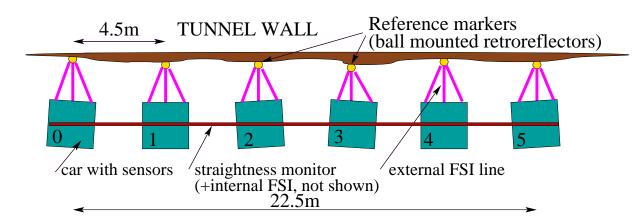

Alignment involves:

- 1. accelerator component construction accuracy
- 2. accelerator component fiducialisation
- 3. reference survey (\rightarrow this talk)
- 4. stake out
- 5. position adjustment

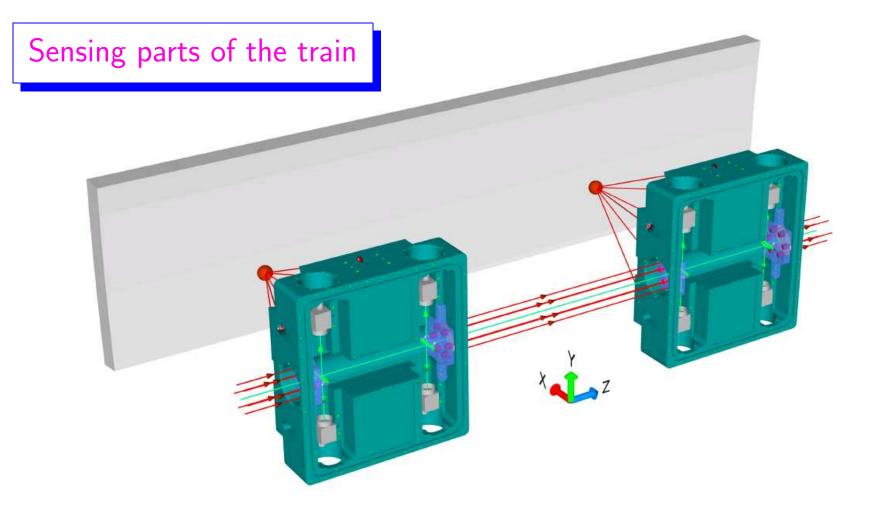

- ILC will operate at ultra low emittance
 → alignment of all components will be
 crucial (cavities, magnets, bpm's, etc.)
- long tunnel ($\sim 50 \, km$ incl. Dumping Rings) to survey: fast, automated measurement needed (realign with minimum shutdown time)
 - tight free space ($\approx 1 \, m$ wide)
 - no long term stable reference monuments (LEP: $100 \ \mu m/year$) \rightarrow survey must be regularly repeated (1-2 times per year)
 - biggest problem of open air techniques: refraction

LiCAS-RTRS train: principle of operation

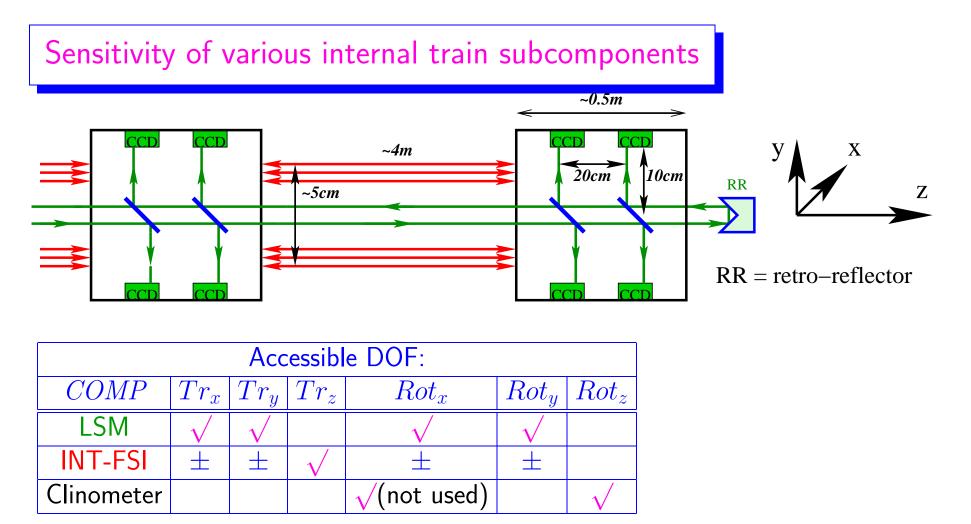

- RTRS: Rapid Tunnel Reference Surveyor mechanical concept of the survey train developed at DESY for TESLA
- collider alignment at construction stage: $200 \,\mu m$ over $600 \,m$ in vertical (example TESLA specification)
- LiCAS: Linear Collider and Survey, proposed technology: optical measurements using FSI (Frequency Scanning Interferometry) and Laser Straightness Monitors (LSM) (internal laser beam lines in vacuum)
- More details incl. internal distance measurements on next slide

- automatic train measures reference markers (i.e. defines the reference frame)
- later measure collider position w.r.t. the above co-ordinate system
- internal laser lines in vacuum
- prototype installation at DESY started in Summer 2006
 - \rightarrow see LiCAS overview talk in this Workshop

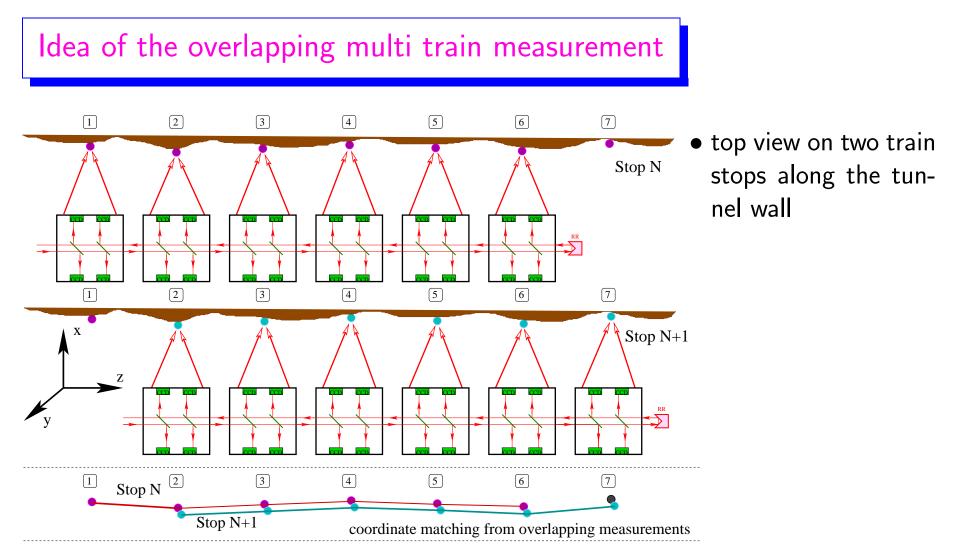

- Important components for the simulation (Laser Straightness Monitor, FSI lines):
 - LSM: 1 laser line per train; 2 beam splitters, 4 CCD cameras per car
 - Internal FSI: 6 laser lines, 6 retro-reflectors per car
 - External FSI: 6 laser lines per car, 1 wall marker in front of each car
 - clinometer (not shown) for Rot_z

• LSM: transverse translation $(Tr_{x,y}, \sigma \approx 0.3 \mu m)$ and rotation $(Rot_{x,y}, \sigma \approx 3.0 \mu rad)$

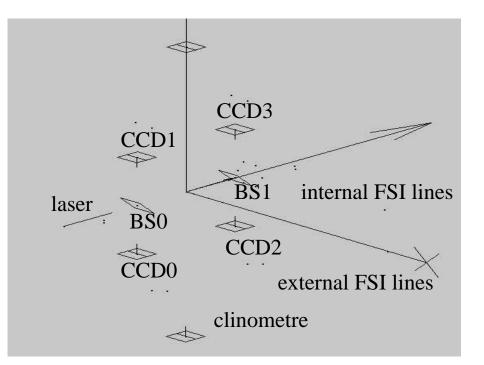

- INT-FSI: longitudinal distance ($\sigma \approx 1 \mu m$) (\pm redundancy for LSM)
- Clinometer: only Rot_z used (insensitive to the geoid shape)

- each train stop provides coordinates of N (=6) wall markers expressed in the local frame of the train
- overlapping measurements of each wall marker
- local measurements are combined to coincide on the same trajectory in the global tunnel frame (simultaneous fit to all measurements)

SIMULGEO: Software used in the simulation

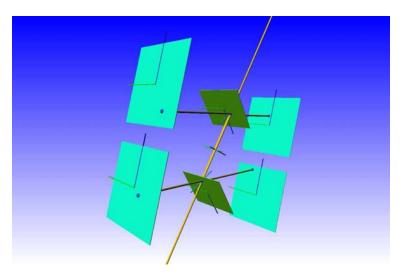

- Object oriented script language for description of opto-geometrical systems
- Mechanical correlations between objects grouped in local frames
- ERROR PROPAGATION MODE: Performs full error propagation (N² matrix, very CPU consuming)

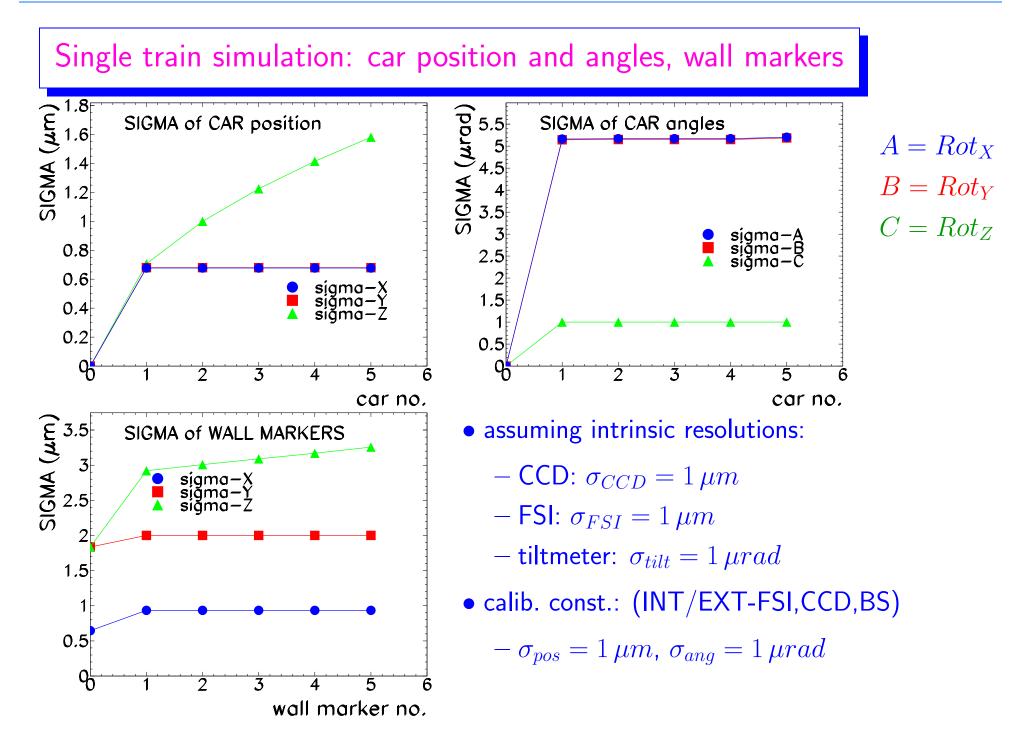

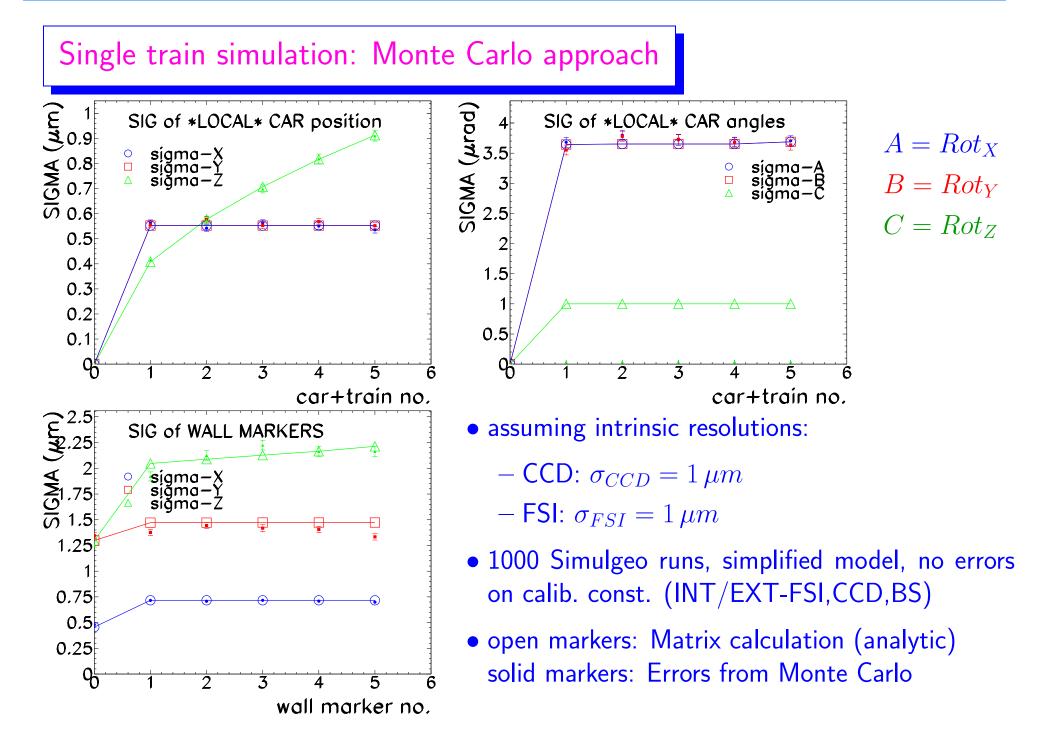

LiCAS Ray-Tracer, Reconstruction and train Monte Carlo

- Ray Tracer: generating (for a given geometry) all CCD, internal and external FSI measurements
- Running SIMULGEO in RECONSTRUCTION MODE. Solving the geometry of the system using provided "experimental" measurements. (Input from ray-tracer).
- smearing of the measurements with sensor resolution, running many train journeys in a loop:

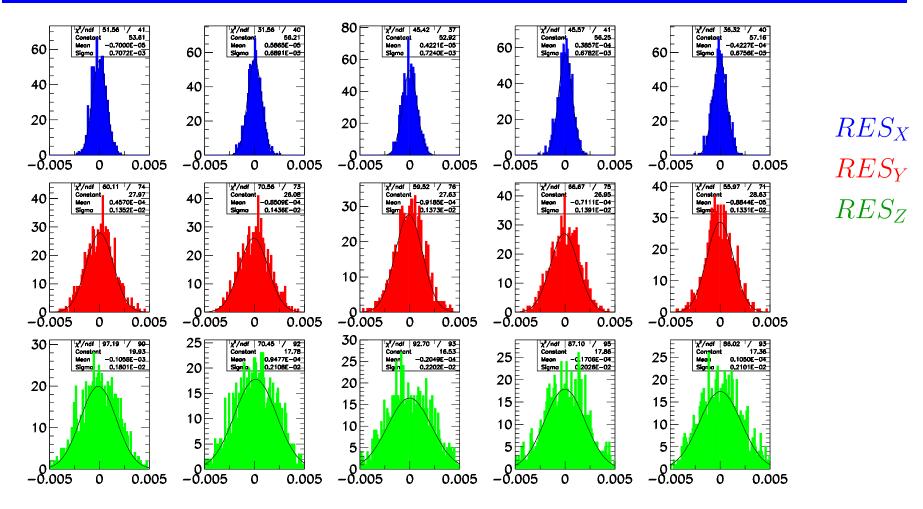

Monte Carlo approach to error propagation (allows also to study error distribution)

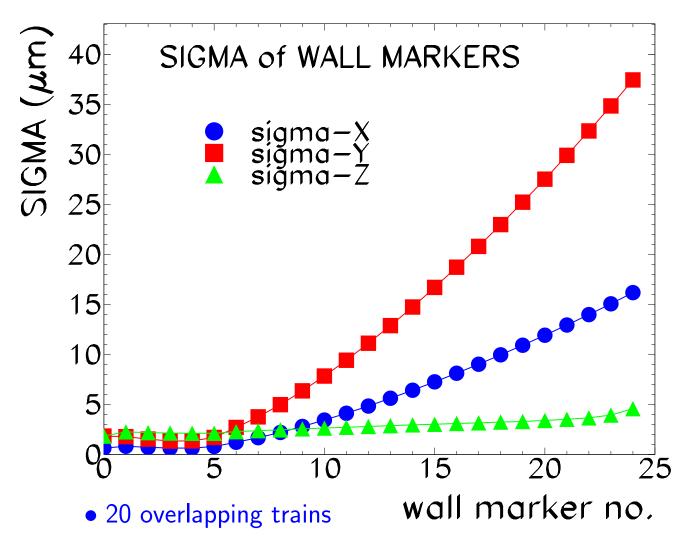

Residua distribution (Reconstructed - Generated) for Wall Markers

• 1000 SIMULGEO runs for 1 LiCAS train (smearing only for CCD and FSI)

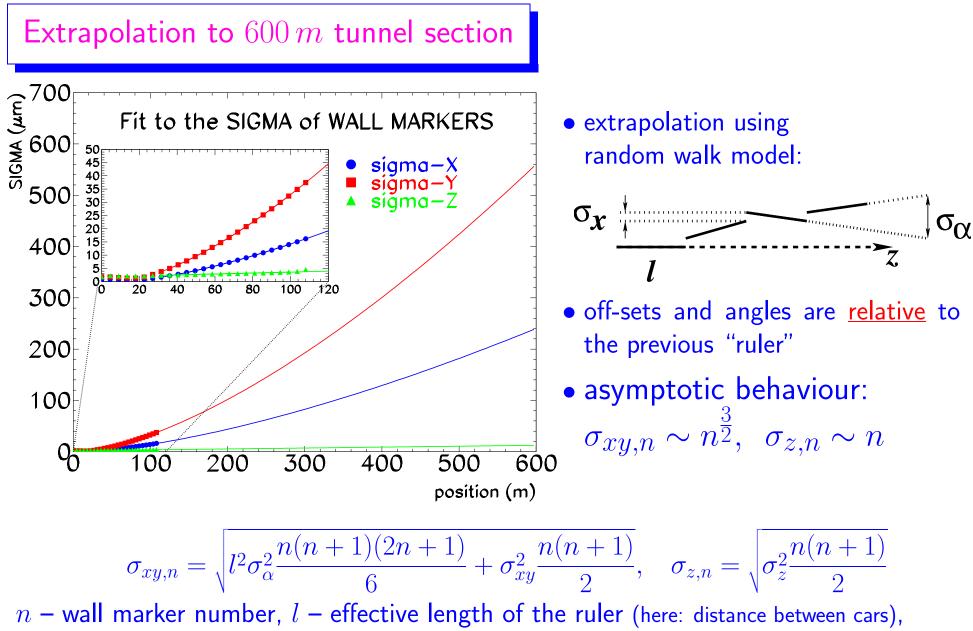

- Nice Gaussian shapes, no bias on reconstructed mean value (X axis in [mm])
- More study on systematic effects soon

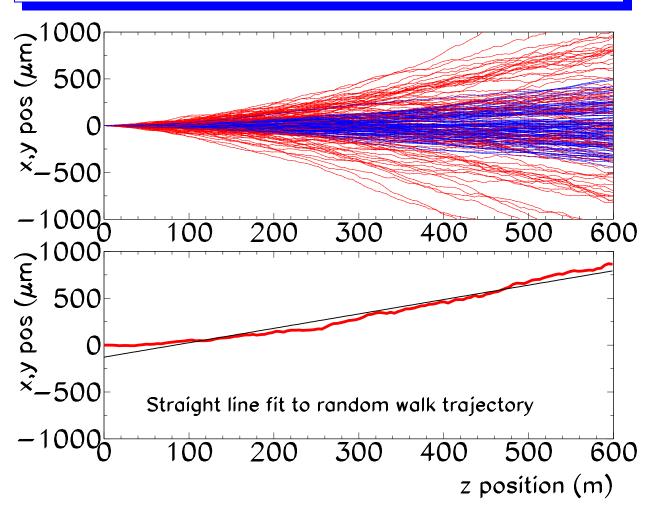

- results of full SIMULGEO simulation (error matrix rank $N^2 \sim 10000^2$)
- fast growth of transverse errors !

• train stops are coupled to each other via the (previously measured) wall markers

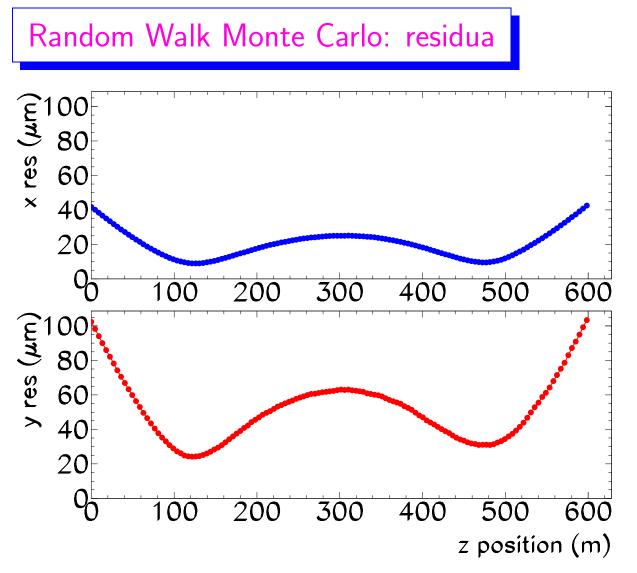

errors: σ_{α} – angular (~ 0.1 μrad), σ_{xy} – transverse (~ 0.5 μm), σ_z – longitudinal (~ 0.1 μm)

Random Walk Monte Carlo: trajectories, fits

- trajectories generated from Random Walk Monte Carlo using parameters from the fit to SIMULGEO points (X, Y) direction
 - good news: points along trajectories are strongly correlated (ie.: small 'oscillations' observed)
 - straight line fits to the Random Walk paths for 600 mtunnel section

• repeating this procedure for many "numerical experiments"...

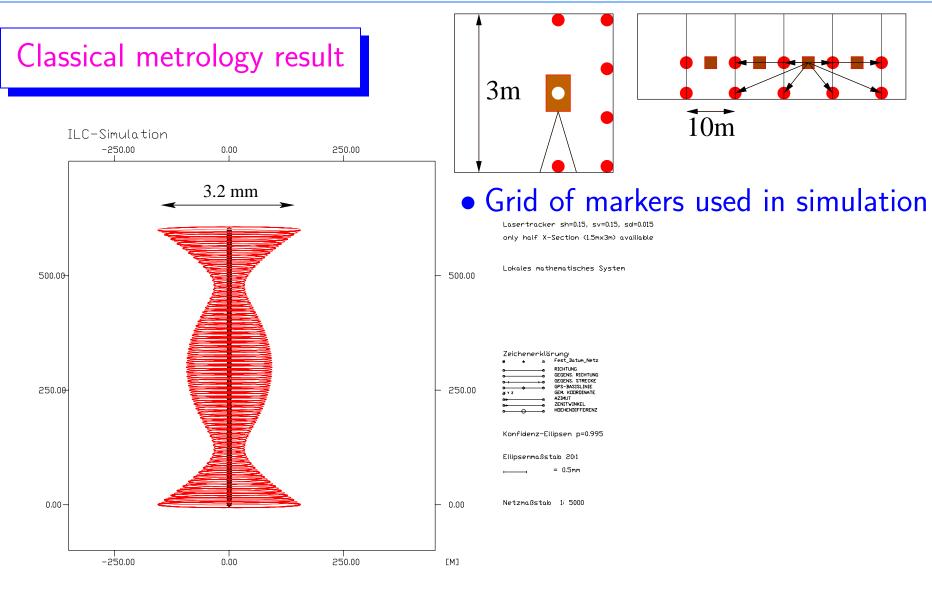

- mean deviation from straight line fits (X, Y) direction
- realistic input to the simulations of beam dynamics

- well below specification: $\sigma_x = 500 \mu m$, $\sigma_y = 200 \mu m$
- however: only statistical errors included

• precision between X – Y can be swapped by changing the marker location (horizontal to vertical position)

Simulation of the LiCAS survey train

- using Lasertracker ($\sigma_h = 0.15 mgon, \sigma_v = 0.15 mgon, \sigma_d = 0.015 mm$)
- Neglecting refraction in air !

Summary

- LiCAS technology is capable of surveying the ILC tunnel to desired accuracy: $\mathcal{O}(200) \, \mu m$ over $600 \, m$ tunnel section
- Reconstruction procedure for wall markers positions using CCD and FSI readout for single and many train stops was developed
- Systematics errors under study (using Monte Carlo approach)
- Work in progress on the train calibration procedure (LSM,FSI,...) \rightarrow next plans:
 - determine sensitivity to different calibration parameters
 - find method of $in \ situ$ calibration
