Measurement of the CKM angle $\phi_2(\alpha)$

A. Somov  
University of Cincinnati, Cincinnati, Ohio 45221, USA

We present recent measurements of the unitarity triangle angle $\phi_2(\alpha)$ using $B \to \pi \pi$, $B \to \rho \rho$, and $B \to \rho \pi$ decays. The measurements are based on data samples collected with the Belle and BaBar detectors at the KEKB and PEP-II $e^+ e^-$ colliders, respectively. We also report on a new measurement of a $CP$-violating asymmetry in $B^0 \to a_1^+ \pi^-$ decay which will allow to constrain further the angle $\phi_2$.

I. INTRODUCTION

The $CP$ violation in the standard model (SM) can be described by the presence of a complex phase in the three-generation Cabibbo-Kobayashi-Maskawa [1] (CKM) quark-mixing matrix. Unitarity constraints on the matrix elements lead to six relations, one of the most interesting is $V_{ud}V^*_{ub} + V_{cd}V^*_{cb} + V_{td}V^*_{tb} = 0$. This relation can be depicted as a triangle in the complex plane as shown in Fig 1. Checking unitarity of the CKM matrix implies measuring sides and angles of the triangle. This provides an important test of the SM. The phase angle $\phi_2$ [2], defined as $\arg[-(V_{td}V^*_{tb})/(V_{cd}V^*_{ub})]$, represents the phase difference between $V_{td}$ and $V_{ub}$. It can be determined by measuring a time-dependent $CP$ asymmetry in charmless $B \to u\bar{u}d$ decays such as $B^0 \to \pi^+ \pi^-, \pi^+ \pi^- \pi^0, \rho^+ \rho^-$, and $a_1^+ \rho^-$. The decay-rate asymmetry in these decays can arise due to the interference between the amplitudes of the direct decay of $B$ and decay after $B\bar{B}$ mixing. The $B$ decays are proceeded mainly through a tree and gluonic penguin loop diagrams as shown in Fig 2. The penguin loop amplitude is irrelevant to the $\phi_2$ and contaminates the measurement. The penguin contribution can be constrained by using isospin relations or employing SU(3) flavor relations, which will be discussed later.

![Fig. 1: The CKM unitarity triangle $V_{ud}V^*_{ub} + V_{cd}V^*_{cb} + V_{td}V^*_{tb} = 0$ in the complex $\bar{\pi} - \pi$ plane.](image)

Snyder and Quinn [4] showed that the angle $\phi_2$ can be determined without discrete ambiguities using a time-dependent Dalitz plot (DP) analysis of $B^0 \to \pi^+ \pi^- \pi^0$ decays. The DP analysis allows one to measure the complex amplitudes of $\pi^+ \pi^- \pi^0$ decays which are related to $\phi_2$ via an isospin relation. Previously a quasi-two-body analysis of $B^0 \to \rho^+ \rho^-$ decays has been used to constrain $\phi_2$ using this decay mode. Recent results on the DP analyses are presented in Section V.

$B^0 \to a_1^+ \pi^-$ is another channel which allows us to extract the angle $\phi_2$. Recently BaBar has measured...
a CP-violating asymmetry in these decays. However
the extraction of $\phi_2$ has not yet been performed for
this channel. It is expected to be done using a flavor
SU(3) symmetry. The measurements in $B^0 \to a_1^+ \pi^-$
decays are described in Section VII.

II. ANALYSES OVERVIEW

Analyses of $B \to \pi \pi$, $B \to \rho \pi$, $B \to \rho \rho$, and $B \to \pi^+ \pi^-$
decays have several common features.

Charged pions are identified using information from
time-of-flight counters and the central tracking chambers.
Most analyses also use information from aerogel
threshold cherenkov counters (Belle) and from a DIRC
detector (BaBar). $B$ decays are selected by combining
charged pions originating from the interaction region,
and adding $\pi^0$s in the decays which involve $\rho^0$
mesons.

$B$ decays are identified using two kinematic vari-
able: the beam-energy-constrained mass $M_{bc} \equiv \sqrt{E^2_{\text{beam}} - p_B^2}$
and energy difference $\Delta E \equiv E_B - E_{\text{beam}}$, where $E_{\text{beam}}$
is the beam energy, and $E_B$ and $p_B$ are the energy and
momentum of the reconstructed $B$ candidate, all evaluated
in the center-of-mass (CM) frame.

Flavor of the $B$ meson accompanying the signal $B$
is identified using a tagging algorithm which identifies
its decay products (mainly leptons and kaons). The
tagging algorithm provides the flavor of the tagged
meson and a tagging quality.

The dominant background originates from $e^+e^- \to q\bar{q}$
($q = u, d, s, c$) continuum events. The separation of
continuum background from the signal events can
be done using the event topology: $q\bar{q}$ events tend to
be more jet-like while $B\bar{B}$ events are more spherical
in the CM frame.

The Belle analyses use event-shape variables, specifically,
16 modified Fox-Wolfram moments [2] combined into a Fisher discriminant [3]. We form signal
and background likelihood functions $L_s$ and $L_{BG}$
by multiplying a probability density function (PDF) for
the Fisher discriminant by a PDF for $\cos \theta_B$, where
$\theta_B$ is the polar angle in the CM frame between the
$B$ direction and the beam axis. The PDFs for signal
and $q\bar{q}$ are obtained from Monte Carlo (MC)
simulations and the data sideband, respectively. We calculate
the ratio $R = L_s/(L_s + L_{BG})$. The continuum
background is reduced by setting a threshold on $R$.
In $B^0 \to \rho^+ \rho^-$ analysis PDFs for $R$ are included into
a likelihood function. In some analyses we also set
a threshold on the absolute value of the cosine of the
angle between a thrust axis of the reconstructed signal
$B$ meson and that of the rest of the event, $\cos_{th}$.

In the BaBar analyses the $q\bar{q}$ background is usu-
ally removed by directly applying thresholds on $\cos_{th}$
and on the second-to-zeroth Fox-Wolfram momentum
$R_2$. Further discrimination is achieved by using an
artificial neural network which includes event shape
variables. The neural net is trained using MC simu-
lated events and off-peak data. The output of the net, $N$
is included as a PDF into the fitting likelihoods.

The decay time difference $\Delta t$ between the two $B$
mesons can be determined by measuring the distance
between the decay vertices of these mesons. Since
the $B^0$ and $\bar{B}^0$ are produced approximately at rest in
the $\Upsilon(4S)$ CM system, $\Delta t \approx \Delta z/c$, where $c$
is the speed of light and $\beta\gamma$ is a Lorentz boost of the $\Upsilon(4S)$
mesons and equals 0.425 (0.559) for Belle (BaBar).

The decay vertices of the signal and tag-side $B$ mesons
are reconstructed by fitting charged tracks that have
hits in the silicon vertex detector using an interaction
point constraint.

III. $B^0 \to \pi^+ \pi^-$

The time-dependent rate for $B \to \pi^+ \pi^-$ decays
tagged with $B^0(Q = +1)$ and $\bar{B}^0 (Q = -1)$ mesons
is given by

$$P_{\pi\pi}(\Delta t) = \frac{e^{-|\Delta t|/\tau_B^0}}{4\tau_B^0} \{1 + Q[A \cos(\Delta m \Delta t)]$$

$$+ S \sin(\Delta m \Delta t)\},$$

where $\tau_B^0$ is the $B^0$ lifetime, $\Delta m$ is the mass difference
between the two $B^0$ mass eigenstates, $\Delta t$ is the
proper-time difference between the two $B$ decays in
the event, and $A$ and $S$ are CP asymmetry co-
efficients which are to be obtained from a fit to the data.
If the decay amplitude is dominated by a tree
diagram, $S = \sin(2\phi_2)$ and $A = 0$. The presence of an
amplitude with a different weak phase (such as from
a gluonic penguin diagram) gives rise to direct CP
violation and shifts $S$ from $\sin(2\phi_2)$:

$$S_{\text{meas}} = \sqrt{1 - A^2_{\text{meas}}} \sin 2\phi^\text{eff}_2,$$  \(2\)

where $A, S_{\text{meas}}$ are measured coefficients, $\phi^\text{eff}_2 = \phi_2 +
\delta\phi_2$, and $\delta\phi_2$ is the phase shift.

FIG. 3: The isospin triangles for $B \to \pi \pi$ decays. The
amplitudes $A$ are defined as $A = e^{i2\phi_3} A$. The
Belle analysis [4] is based on a data sample
consisting of 535 million $B\bar{B}$ pairs. The analysis is
organized in two steps. We first determine the yields

fp1p07_141
of signal and background components using an unbinned extended maximum likelihood (ML) fit to $M_{bc}$, $\Delta E$, and the kaon identification probability $x_{\pm}$ for the positively and negatively charged tracks. The fit yields $1464 \pm 65 \ \pi^+\pi^-$ candidates. We subsequently perform a fit to the $\Delta t$ distribution for the $CP$ parameters $A$ and $S$. The fit to 16831 events yields $A_{\pi^+\pi^-} = 0.55 \pm 0.08(stat) \pm 0.05(syst)$ and $S_{\pi^+\pi^-} = -0.61 \pm 0.10(stat) \pm 0.04(syst)$.

The BaBar measured the $CP$-violating parameters using a sample of 383 million $B\bar{B}$ events [9]. The $CP$-violating parameters are obtained from an unbinned extended ML fit to 309540 events. The likelihood function is a combined constraint from Belle and BaBar. The curve represents Belle measurements only; the dot-dashed line is a combined constraint from Belle and BaBar.

The angle $\phi_2$ can be extracted using an isospin relations [11]. The $SU(2)$ isospin symmetry allows one to relate the amplitudes $A^{+0}$, $A^{+0}$, and $A^{00}$ of the $B \to \pi^+\pi^-$, $\pi^+\pi^0$, and $\pi^0\pi^0$ decays and corresponding amplitudes $\bar{A}$ for the charge-conjugated processes as follows

\[
\frac{1}{\sqrt{2}} A^{+0} + A^{00} = A^{+0}
\]
\[
\frac{1}{\sqrt{2}} A^{+0} + A^{00} = \bar{A}^{-0}.
\] (3)

These relations lead to two triangles in the complex plane as shown in Fig 3. The angle between these triangles is the phase difference $2\delta \phi_2$. There are six unknown parameters (five amplitudes, and the angle $\phi_2$) and six observables: the branching fractions for $B \to \pi^+\pi^-$, $\pi^+\pi^0$, and $\pi^0\pi^0$, the $CP$ parameters $A_{\pi^+\pi^-}$ and $S_{\pi^+\pi^-}$ and the time integrated asymmetry $A_{\pi^+\pi^0}$ for $B^0 \to \pi^0\pi^0$ decays. The angle $\phi_2$ can be determined with an eight-fold ambiguity corresponding to four possible orientations of the isospin triangles and the two fold ambiguity from solving Eq. 2. The confidence level (C.L.) for $\phi_2$ obtained by the CKMfitter group [12] is presented in Fig. 4. The curves on this plot correspond to the Belle (BaBar) measurements only and to the combined Belle and BaBar constraint. The combined constraint is obtained using averaged measurements of the branching fractions and asymmetries. The eight peaks in the 1-C.L. distribution for BaBar (dot-dashed curve) correspond to the eight-fold ambiguity. However the Belle constraint contains only 4 peaks. This can be explained by the large value of the measured asymmetry $A_{\pi^+\pi^-} = 0$; one of the isospin triangle becomes flat, an apex of the triangle lies on the base. This leads to merging of the two solutions and to the four-fold ambiguity on $\phi_2$. The combined Belle and BaBar constraint on $\phi_2$ consistent with the standard model is $93.5^{+12.1}_{-10.0}$ at 68% C.L.

IV. $B^0 \to \rho^+\rho^-$

As it was discussed in previous section, $B \to \pi\pi$ decays constrain $\phi_2$ with a four-fold ambiguity. In order to choose a single solution and further constrain the angle $\phi_2$ one can exploit other decay channels. In particular, $\phi_2$ can be determined by measuring $CP$-violating parameters in $B^0 \to \rho^+\rho^-$ decays. $B^0 \to \rho^+\rho^-$ channel have several advantages comparing with $B^0 \to \pi^+\pi^-$:

- The branching fraction for $B^0 \to \rho^+\rho^-$ decays is about 4.4 times larger than that for $B^0 \to \pi^+\pi^-$.

- The size of the penguin amplitude in $B^0 \to \rho^+\rho^-$ decays is constrained to be small with respect to the leading tree diagram by the small branching fraction of $B^0 \to \rho^0\rho^0$ [13].
However there are certain complications in the measurement of $\phi_2$:

- The relatively large width of $\rho$ mesons ($\sim 150$ MeV) leads to a substantial combinatorial background in $\rho^+\rho^-$ decays.

- $\rho^+\rho^-$ is a vector-vector final state. The CP-violating parameters receive contributions from a longitudinally polarized state (CP-even) and two transversely polarized states (an admixture of CP-even and CP-odd states). However, recent measurements of the polarization fraction by Belle [14] and BaBar [15] show that the longitudinal polarization fraction is near unity ($f_L = 0.968 \pm 0.023$) [10].

- The isospin analysis in $B \to \rho \rho$ decays can be complicated by a possible contribution of the isospin $I = 1$ amplitude which might appear due to the finite width of $\rho$ mesons. Similar to $B^0 \to \pi^+\pi^-$ decays, electroweak penguin amplitudes can contribute to the $B^0 \to \rho^+\rho^-$ decays. However both these contributions are expected to be small [16].

Belle measured CP-violating parameters using 535 million $B\bar{B}$ pairs. Similar to $B^0 \to \pi^+\pi^-$ analysis, the measurements are done in two steps: we first obtain the yields of signal (an background components using an unbinned extended ML fit to the three-dimensional $(M_{bc}, \Delta E, R)$ distribution. A fit to 176843 events yields $N_{\rho^+\rho^-} = 576 \pm 53$. We subsequently perform a fit to the $\Delta t$ distribution to determine the $CP$ parameters $A$ and $S$. The time dependent decay rate for $B \to \rho^+\rho^-$ decays is given by Eq. 1. The likelihood function includes the following event categories: signal and $\rho\rho\pi$ non-resonant decays, signal decays that have at least one $\pi$ meson incorrectly identified (referred to as SCF events), continuum background $(q\bar{q})$, $b \to c$ background, and charmless ($b \to u$) background. The fit results are $A = 0.16 \pm 0.21 \pm 0.08$ and $S = 0.19 \pm 0.30 \pm 0.08$.

BaBar analysis [12] is based on a data sample of 347 million $B\bar{B}$ pairs. The signal yield, $f_L$, and CP-violating parameters are obtained simultaneously from an unbinned extended ML fit to 33902 events. The background discriminating variables are $m_{ES}, \Delta E, \Delta t, m_{\pi\pi}, \cos \phi$, and $N$. PDFs for these variables are included in the likelihood function while the event selection requirements are lowered. The fit results are $N_{\rho^+\rho^-} = 615 \pm 57, f_L = 0.977 \pm 0.024$, $C = -0.07 \pm 0.15 \pm 0.06$ and $S = -0.19 \pm 0.21 \pm 0.07$. The CP-violating parameters measured by BaBar are consistent with those obtained by BaBar. The values of $A_{\rho^+\rho^-}$ and $S_{\rho^+\rho^-}$ are also consistent with no CP violation $(A = S = 0)$.

The angle $\phi_2$ can be constrained using an isospin analysis similar to that used in $B \to \pi\pi$ decays. The six underlying parameters are: five decay amplitudes for $B \to \rho\rho$ and the angle $\phi_2$. The observables are the branching fractions for $B \to \rho^+\rho^-, \rho^+\rho^0$ [10], and $\rho^0\rho^0$ [13]; the $CP$ parameters $A$ and $S$; and the parameter $A_{\rho\rho\rho}$ for $B \to \rho^0\rho^0$ decays. The last parameter is not yet measured, but nevertheless one can constrain $\phi_2$. We apply the isospin relations to the decay amplitudes corresponding to the longitudinal polarization (CP-even state). The branching fractions are multiplied by the corresponding longitudinal polarization fractions. We neglect possible contributions from electroweak penguins and $I = 1$ amplitudes [10] and possible interference between signal and non-resonant components. The resulting function 1−C.L. obtained by the CKMfitter group is shown in Fig. 5. The curves on this plot correspond to the Belle (BaBar) measurements only and to a combined constraint. The combined constraint is obtained using averaged measurements of the branching fractions and asymmetries. The distribution has more than one peak due to ambiguities that arise when solving for $\phi_2$. The “flat-top” regions in Fig. 5 arise because $A_{\rho^0\rho^0}$ is not measured. The absence of the flat-top regions in Belle measurements can be explained by the fact that the isospin triangle is not closed; the relatively large measured branching fraction of $B^\pm \to \rho^\mp\rho^0$ decay leads to the squashed triangle. This results in only a two-fold ambiguity on $\phi_2$. The solution consistent with the standard model is $72.5^\circ < \phi_2 < 111.5^\circ$ at 68% C.L.
Recently, an alternative model-dependent approach to extract $\phi_2$, using flavor $SU(3)$ symmetry has been proposed [17]. This method could potentially give more stringent constraints on $\phi_2$.

V. $B^0 \to \rho^+\pi^-$

An alternative way to measure the angle $\phi_2$ is to perform a time-dependent Dalitz plot analysis in $B^0 \to \pi^+\pi^-\pi^0$ decays. It was pointed out by Snyder and Quinn [4] that the Dalitz analysis allows one to determine $\phi_2$ without discrete ambiguities. The time-dependent rate for $B^0 \to \pi^+\pi^-\pi^0$ decays is given by

$$P(\Delta t, d\bar{x}_+, d\bar{x}_-) \sim e^{-|\Delta t|/\tau_{B^0}} \left\{ \left( |A_{3\pi}^0|^2 + |\mathcal{A}_{3\pi}|^2 \right) - Q \times \left( |A_{3\pi}^0|^2 - |\mathcal{A}_{3\pi}|^2 \right) \cos(\Delta m \Delta t) - 2\text{Im} \left[ \frac{q}{p} A_{3\pi}^0 \mathcal{A}_{3\pi} \right] \sin(\Delta m \Delta t) \right\} ,$$

where $Q = +1(-1)$ corresponds to $B^0(\bar{B}^0)$ tags, the parameters $q$ and $p$ are the mass eigenstates of neutral $B$ mesons with the mass difference $\Delta m$, and the $\tau_{B^0}$ is the $B^0$ meson average lifetime. The amplitudes $A_{3\pi}^0(\mathcal{A}_{3\pi})$ of the $B^0(\bar{B}^0)$ decays depend on the Dalitz plot variables $s_{+,-} = (p_{+,-} + p_0)^2$ and $s_0 = (p_+ + p_-)^2$, where $p_{+,-,0}$ are the four-momenta of the $\pi^+\pi^-\pi^0$. The amplitudes can be factorized as follows

$$A_{3\pi}(s_{+,-}) = \sum_{\kappa = +,-,0} T^\kappa_B F^\kappa(s_\kappa) A^\kappa,$$

$$\frac{q}{p} A_{3\pi}(s_{+,-}) = \sum_{\kappa = +,-,0} T^\kappa_B F^\kappa(s_\kappa) \mathcal{A}^\kappa,$$

where $T^\kappa_B$, $F^\kappa(s_\kappa)$, and $A^\kappa(\mathcal{A}^\kappa)$ are helicity distributions, lineshapes, and complex amplitudes corresponding to $B^0(\bar{B}^0) \to \rho^+\pi^-\rho^-\pi^+, \rho^+\pi^-\rho^0\pi^0$ decays for $\kappa = +,-,0$. The lineshapes $F^\kappa(s)$ is modeled as a sum of the $\rho(770)$ resonance and its radial excitations $\rho(1450)$, and $\rho(1700)$:

$$F^\kappa(s) = B\rho(770) + \beta B\rho(1450) + \gamma B\rho(1700),$$

where $B$ are Breit-Wigner functions and $\beta$ and $\gamma$ are the relative complex amplitudes of the two resonances. Inserting Eq. (3) and Eq. (6) to Eq. (4) one obtains 26 free parameters which are to be determined from a fit to the data.

The Belle analysis [18] is based on a data sample of 449 million $B\bar{B}$ pairs. We first obtain the signal yield from an unbinned extended ML fit to the $M_{bc} - \Delta E$ and Dalitz plot distribution. The fit yields $971 \pm 42 B^0 \to \pi^+\pi^-\pi^0$ events. The lineshape parameters $\beta$ and $\gamma$ are determined from a time-integrated Dalitz plot fit with a larger Dalitz plot acceptance. The 26 coefficients are subsequently determined from a Dalitz-$\Delta t$ fit to the 2824 events in a small signal region. The measured parameters also allow to extract a ratio $B(B^0 \to \rho^0\pi^0) / B(B^0 \to \rho^+\pi^-)$ which is measured to be $0.133 \pm 0.022 \pm 0.023$. This value is consistent with a Belle previous measurement of the branching fraction of $B^0 \to \rho^0\pi^0$ decays using a quasi-two-body approach [19].

BaBar performed analysis using 375 million $B\bar{B}$ pairs [20]. The 26 coefficients and event yields are obtained simultaneously from an unbinned extended ML fit. The likelihood function contains in total 68 parameters which are varied in the fit. The fit yields $N_{3\pi} = 2067 \pm 68$ candidates.

The measured amplitudes $A^\kappa$ and $\mathcal{A}^\kappa$ can be related to the angle $\phi_2$ using an isospin relation [21] for neutral $B$ decays only

$$e^{2i\phi_2} = \frac{\mathcal{A}^+ + \mathcal{A}^- + 2A^0}{A^+ + A^- + 2A^0}.$$
\[ \rho^{\pm} \pi^{\mp} \), \( \mathcal{B}(B^{+} \rightarrow \rho^{+} \pi^{0}) \), \( \mathcal{B}(B^{+} \rightarrow \rho^{0} \pi^{+}) \) and asymmetries for \( \mathcal{A}(B^{+} \rightarrow \rho^{+} \pi^{0}) \) and \( \mathcal{A}(B^{+} \rightarrow \rho^{0} \pi^{+}) \) decays\[10\] into the isospin analysis (a pentagon isospin analysis). As an example, 1 - C.L. curves on \( \phi_{2} \) obtained by Belle from the Dalitz analysis and from the full Dalitz and pentagon combined analysis are presented in Fig. 7. Combined Belle and BaBar Dalitz and pentagon constrain is being recently prepared by the CKMfitter group.

**Fig. 7:** 1 - C.L. vs \( \phi_{2}(\alpha) \) obtained by Belle. The dotted curve represents the Dalitz analysis and the solid curve represents the combined Dalitz and an isospin pentagon analysis.

**VI.** \( B^{0} \rightarrow a_{1}^{\pm} \pi^{\mp} \)

Another channel which allows to measure \( \phi_{2} \) is \( B^{0} \rightarrow a_{1}^{\pm} \pi^{\mp} \). As the final state \( a_{1}^{\pm} \pi^{\mp} \) is not a CP eigenstate, one has to consider four decay modes with different charge and flavor combinations: \( B^{0} \rightarrow a_{1}^{\pm} \pi^{\mp} \) and \( \overline{B}^{0} \rightarrow a_{1}^{\mp} \pi^{\pm} \). The decay rates can be written as\[22\]

\[
\mathcal{P}_{a_{1}^{\pm} \pi^{\mp}}(\Delta t) = (1 \pm a_{C_{1}^{\pi} F_{1}}^{a_{1}^{\pm} \pi^{\mp}}) \frac{e^{-|\Delta t|/\tau_{B}^{0}}}{4T} \{1 - Q \times \\
[(C_{a_{1}^{\pi}} + \Delta C_{a_{1}^{\pi}}) \cos(\Delta m_{d} \Delta t) - \\
(S_{a_{1}^{\pi}} + \Delta S_{a_{1}^{\pi}}) \sin(\Delta m_{d} \Delta t)] \} , \]  

where \( \Delta t = t_{\rho} - t_{\tau} \) is the proper-time difference between the fully reconstructed and the associated \( B \) decay, and \( Q = +1(-1) \) corresponds to \( B^{0}(\overline{B}^{0}) \) tags. The parameters \( S_{a_{1}^{\pi}} \) and \( C_{a_{1}^{\pi}} \) are associated with mixing-induced CP violation (related to \( \phi_{2} \)) and flavor-dependent direct CP violation, respectively. The parameters \( \Delta S_{a_{1}^{\pi}} \) and \( \Delta C_{a_{1}^{\pi}} \) describe the asymmetry between the rates \( \Gamma(B^{0} \rightarrow a_{1}^{-} \pi^{+}) + \Gamma(\overline{B}^{0} \rightarrow a_{1}^{+} \pi^{-}) \) and \( \Gamma(B^{0} \rightarrow a_{1}^{+} \pi^{+}) + \Gamma(\overline{B}^{0} \rightarrow a_{1}^{-} \pi^{-}) \). \( \Delta S_{a_{1}^{\pi}} \) depends in addition on difference in strong phases between the amplitudes contributing to \( B \rightarrow a_{1} \pi \) decays.

The parameters \( C, \Delta C, S, \) and \( \Delta S \) have recently been measured by BaBar collaboration using a data sample of 384 million \( B \overline{B} \) pairs\[23\]. The likelihood function includes the following components: signal, generic \( B \overline{B} \) background, continuum \( q\bar{q} \) background, \( B^{0} \rightarrow a_{1}^{\pm}(1320)\pi^{\mp} \), and non-resonant \( \rho \pi \). The fitting observables are \( m_{ES}, \Delta E, \) a Fisher discriminant \( F \) for continuum suppression, \( m_{a_{1}}, \Delta t \) and an angle between the flight direction of the bachelor pion from \( B \) meson and normal to the plane of the 3\( \pi \) resonance calculated in the 3\( \pi \) rest frame. An unbinned extended ML fit to 29300 events yields 608±53 signal events and the following parameters: \( C_{a_{1}^{\pi}} = -0.10 \pm 0.15 \pm 0.09, \, \Delta C_{a_{1}^{\pi}} = 0.26 \pm 0.15 \pm 0.07, \, S_{a_{1}^{\pi}} = 0.37 \pm 0.21 \pm 0.07, \, \Delta S_{a_{1}^{\pi}} = -0.14 \pm 0.21 \pm 0.06, \) and \( A_{C_{a_{1}^{\pi}}} = -0.07 \pm 0.07 \pm 0.02 \). These measurement indicate no direct and mixing-induced CP violation in \( B^{0} \rightarrow a_{1}^{\pm} \pi^{\mp} \) decays. As shown in\[22\], the effective angle \( \phi_{2}^{eff} \) can be calculated as follows

\[
\phi_{2}^{eff} = \frac{1}{4} \left[ \arcsin \left( \frac{S_{a_{1}^{\pi}} + \Delta S_{a_{1}^{\pi}}}{\sqrt{1 - (S_{a_{1}^{\pi}} + \Delta S_{a_{1}^{\pi}})^{2}}} \right) + \arcsin \left( \frac{S_{a_{1}^{\pi}} - \Delta S_{a_{1}^{\pi}}}{\sqrt{1 - (S_{a_{1}^{\pi}} - \Delta S_{a_{1}^{\pi}})^{2}}} \right) \right] . \]  

\( \phi_{2}^{eff} = \phi_{2} + \delta \phi_{2} \) is measured to be 78.6° ± 7.3°. The extraction of \( \phi_{2} \) can be performed using an SU(3) flavor symmetry\[22\]. However it cannot be done at the moment as branching fractions for SU(3)-related decays have not yet been measured.

**VII. SUMMARY**

We have discussed the measurements of the CKM phase angle \( \phi_{2} \) using \( B \rightarrow \pi \pi, \rho \rho, \pi \pi, \) and \( a_{1}^{\pm} \pi^{\mp} \) decays. The combined constraint for the first three channels is presented in Fig. 8. There are two preferred regions around 88° and 115°. This can be explained by the fact that the \( \phi_{2} \) preferred region obtained from \( B \rightarrow \pi \tau \) Dalitz analysis doesn’t agree well with that obtained from the isospin analysis of \( B \rightarrow \pi \pi \) and \( B \rightarrow \rho \rho \) decays. The angle \( \phi_{2} \) can be constrained as \( (114.5^{+1.4}_{-1.5})° \) at 68% C.L. (solution around the main peak) and 80.0° < \( \phi_{2} < 122.7° \) at 90% C.L. As it can be seen, there is no 'stringent' constrain at 90% C.L. with the current data. More data are awaited to improve our knowledge on \( \phi_{2} \).

---

FIG. 8: World average constraints on $\phi_2(\alpha)$ obtained from an isospin analyses of $B \to \pi\pi$ (dotted curve) and $B \to \rho\rho$ (dot-dashed curve) decays, and from Dalitz analysis of $B \to \rho\pi$ decays (dashed curve). The hatched region is a combined constraint for these three channels.

[2] Angles $\phi_1$, $\phi_2$, and $\phi_3$ in Belle are referred to as $\alpha$, $\beta$, and $\gamma$ in BaBar.
[3] Charge-conjugate modes are included throughout this paper unless noted otherwise.
[7] BaBar is using a definition $C = -A$.
