ABSTRACT

After the successful LHC operation at the center-of-mass energies of 7 and 8 TeV in 2010-2012, plans are actively advancing for a series of upgrades of the accelerator, culminating roughly ten years from now in the high-luminosity LHC (HL-LHC) project, delivering of the order of five times the LHC nominal instantaneous luminosity along with luminosity leveling. The final goal is to extend the dataset from about few hundred fb\(^{-1}\) to 3000 fb\(^{-1}\) by around 2035 for ATLAS and CMS. In parallel, the experiments need to be kept lockstep with the accelerator to accommodate running beyond the nominal luminosity this decade. Current planning in ATLAS envisions significant upgrades to the detector during the consolidation of the LHC to reach full LHC energy and further upgrades. The challenge of coping with the HL-LHC instantaneous and integrated luminosity, along with the associated radiation levels, requires further major changes to the ATLAS detector. The designs are developing rapidly for a new all-silicon tracker, significant upgrades of the calorimeter and muon systems, as well as improved triggers and data acquisition. This report summarizes various improvements to the ATLAS detector required to cope with the anticipated evolution of the LHC luminosity during this decade and the next.

PRESENTED AT

The Second Annual Conference on Large Hadron Collider Physics
Columbia University, New York, U.S.A
June 2-7, 2014
Figure 1: LHC schedule for the next 20 years with the status of the LHC labeled for the top colored row and the injector status on the bottom colored row. The Long Shutdowns (LS1, LS2, and LS3) will be from 2013 to 2015, mid-2018 to 2019, and 2023 to 2025, respectively. The Phase-0, I, and II upgrades are scheduled for LS1, LS2, and LS3, respectively.

1 Introduction

The LHC will undergo several iterations of improvement starting with the increase of center-of-mass energy to 13 TeV in 2015. Further upgrades will increase instantaneous luminosities from $\sim 1 \times 10^{34}$ cm$^{-2}$s$^{-1}$ to $\sim 2 \times 10^{34}$ cm$^{-2}$s$^{-1}$ during LS2 and from $\sim 2 \times 10^{34}$ cm$^{-2}$s$^{-1}$ to $\sim 5 \times 10^{34}$ cm$^{-2}$s$^{-1}$ during LS3 (Fig. 1).

These increases in luminosity allow increased sensitivity to low cross section processes such as $t\bar{t}H$ production. Precision measurements of Higgs couplings could yield the first indications of Beyond the Standard Model Physics. Direct searches for new physics, such as the search for the supersymmetric top partner, will also benefit from the increase in luminosity (Fig. 2). The current Run 2 limits on the stop quark mass at low LSP mass are at $\sim 700$ GeV. It should be possible to discover (exclude) stop quarks with masses up to 1.2 (1.0) TeV with 300 fb$^{-1}$ and up to 1.2 (1.4) TeV with 3000 fb$^{-1}$.

The upgrades, however, come with great challenges to maintain similar performance under much harsher environments. Without proper upgrades to the ATLAS detector [1] much of the produced luminosity would be lost due to trigger limitations. The focus of the Phase-I and II upgrades is to have similar performance in Run 2 and Run 3 as during Run 1 with significantly increased instantaneous luminosities.

2 Phase-0 upgrade

The Phase-0 upgrade is occurring during the 2013-2015 shutdown and aims at achieving the design center-of-energy collisions of 13 TeV with 25 ns bunch crossing and instantaneous luminosities of $\sim 1 \times 10^{34}$ cm$^{-2}$s$^{-1}$. The centerpiece of this upgrade is the insertable B-layer (IBL). This layer is a 4th silicon tracker module that is installed directly on a new, smaller, aluminum beam pipe with a radius of 25 mm (Fig. 3). The module has a pseudorapidity coverage up to $\eta < 3$ and features 3D and planar sensor design will greatly improve tracking, vertex, and b-jet identification [2].

In addition to the IBL installation, the muon system will be completed along with the installation of updated LAr low voltage power supplies.

3 Phase-I upgrade

The major LHC upgrade for Phase-I in 2018-2019 will be a doubling of the instantaneous luminosity to $\sim 2 \times 10^{34}$ cm$^{-2}$s$^{-1}$. The Phase-I upgrade includes significant improvements to the muon system by the
The LHC upgrade for Phase-II in 2023-2025 increases the instantaneous luminosity to $\sim 5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$. Additionally, by the end of Run 3 the current tracking system would have sustained significant radiation damage. The planned replacement will be an all silicon Inner Tracker (ITk) designed to handle a more than twofold increase in instantaneous luminosity. The inner part of the tracker will be a pixel detector with extended forward tracking. The current outer transition radiation tracker will be replaced by dual layer silicon strip modules (Fig. 6). The aim of the upgrade is to improve the radiation hardness and forward coverage of the tracker.
Further upgrades include the addition of a new hardware trigger resulting in two hardware triggers: level 0 and 1. One of these levels would solely handle tracks while the other trigger uses calorimeter and muon information for trigger decisions.

The calorimeter readout will become even more refined with the full calorimeter granularity available at the trigger level. A faster muon trigger is also a part of the Phase-II upgrade which will help maintain reasonable trigger rates in the high luminosity environment.

5 Conclusions

To continue to increase the precision of our Higgs measurements and probe for new physics with the LHC significant amounts of data are necessary. The proposed upgrade schedule aims at achieving similar performance to Run 1 with large instantaneous luminosity. The upgrades for Phase-I are already at a well defined stage while the Phase-II plans are rapidly developing. With these upgrades the LHC is projected to collect $\sim 3000 \text{ fb}^{-1}$ over two decades which will be essential in studying physics at the TeV scale.
