

From Trieste RICH 2007 “TOF vs. RICH” talk:

10.4.2007

What resolution do we expect to get ?

- A calculation indicates $N_{pe} \sim 50$ for 1 cm-long Fused Silica radiator & Burle/Photonis Bialkali photocathode:

- Expected resolution:**

a) Beam (Radiator length = 10 mm + window):

$$\sigma \sim \sqrt{[\sigma_{\text{MCP-PMT}}^2 + \sigma_{\text{Radiator}}^2 + \sigma_{\text{Pad broadening}}^2 + \sigma_{\text{Electronics}}^2 + \dots]}$$

$$= \sqrt{[(\sigma_{\text{TTS}}/\sqrt{N_{pe}})^2 + \sqrt{((12000\mu\text{m}/\cos\Theta_c)/350\mu\text{m/ps})/\sqrt{12}}]^2 + \sqrt{((6000\mu\text{m}/350\mu\text{m/ps})/\sqrt{12})^2 + (3.42 \text{ ps})^2}] \sim 16.1 \text{ ps}$$

b) Laser ($N_{pe} \sim 50 \text{ pe}^-$):

$$\sigma \sim \sqrt{[\sigma_{\text{MCP-PMT}}^2 + \sigma_{\text{Laser}}^2 + \sigma_{\text{Electronics}}^2 + \dots]}$$

$$= \sqrt{[\sigma_{\text{TTS}}/\sqrt{N_{pe}}]^2 + \sqrt{((\text{FWHM}/2.35)/\sqrt{N_{pe}})^2 + (3.42 \text{ ps})^2}] \sim 5.4 \text{ ps}$$

A TOF counter prototype

Four pads connected via equal-time traces:

Radiator

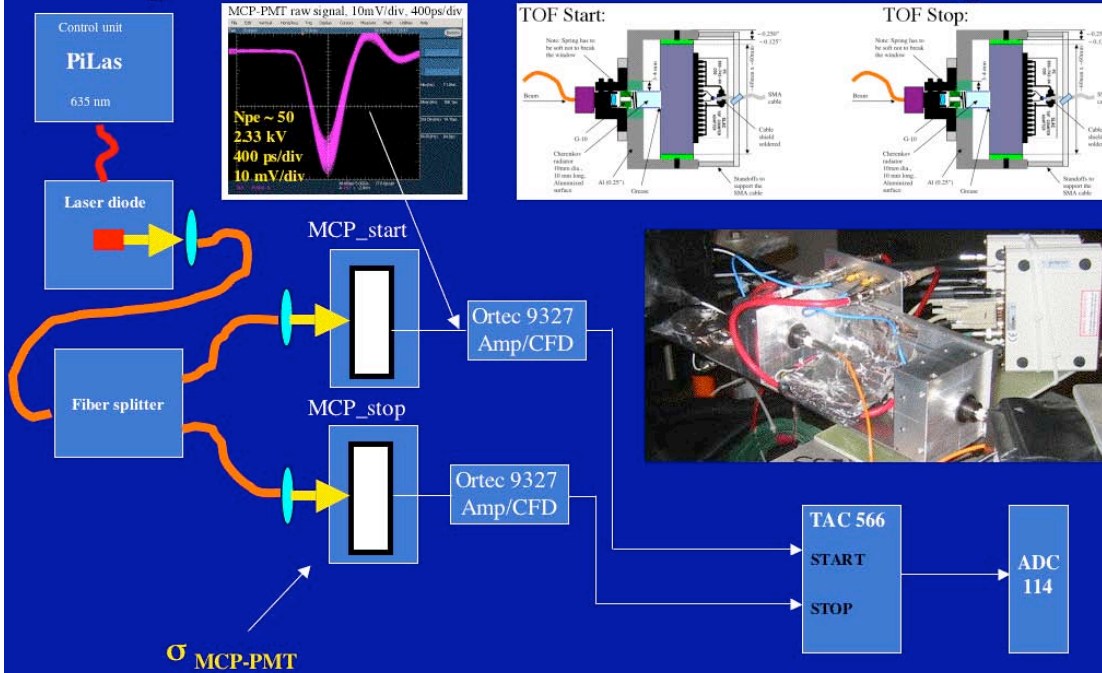

- Burle/Photonis MCP-PMTs with 10 μm MCP holes.
- Short together 4 pads to get a signal; all the rest of pads grounded.
- A 10mm-long, 10mm dia, quartz radiator, Al-coating on cylinder sides.
- Ortec 9327 Amp/CFD & TAC566 & 14 bit ADC114.
- Calculation: 10mm long quartz radiator & a window should give $N_{pe} \sim 50$ pe/track.
- Laser diode light adjusted to provide typically $N_{pe} \sim 50$ pe.
- The laser spot size: ~ 1 mm dia.; beam spot size typically $\sigma \sim 1$ -2mm

21

Calibration of the electronics

A final result with two TOF counters in tandem

Two detector resolution:

Each detector has $N_{pe} \sim 50$ pe⁻:

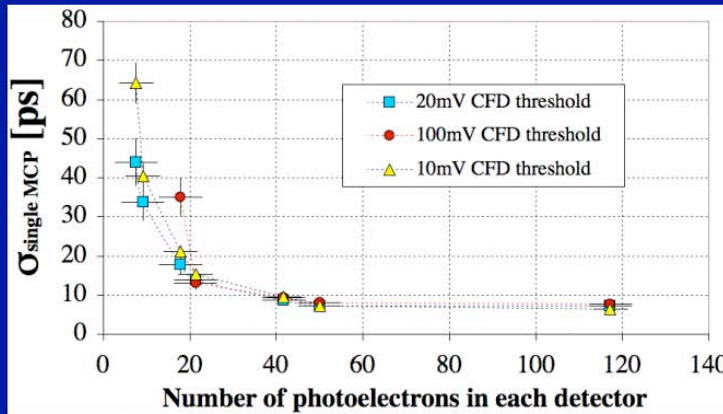

$$\sigma_{\text{single detector}} \sim (1/\sqrt{2}) \sigma_{\text{double detector}} \sim 7.2 \text{ ps}$$

Running conditions:

- 1) Low MCP gain operation ($< 10^5$)
- 2) Linear operation
- 3) CFD discriminator
- 4) No additional ADC correction

- Two Burle/Photonis MCP-PMTs with 10 μm MCP holes operating at 2.27 & 1.88 kV.
- Ortec 9327Amp/CFD (two) with a -10mV threshold and a walk threshold of +5mV & TAC566 & 14 bit ADC114

A single MCP resolution = $f(Npe)_{\text{threshold}}$

CFD threshold:

- 10 mV \Leftrightarrow 2-3 pe
- 20 mV \Leftrightarrow 3-6 pe
- 100 mV \Leftrightarrow 15-20 pe

- Two Burle/Photonis MCP-PMTs with 10 μm MCP holes operating at 227 & 188 kV.
- Ortec 9327AmpCFD (two) with a walk threshold of +5mV & TAC566 & 14 bit ADC114

• Can we aim for a 5mm thick radiator ($Npe \sim 25 pe^-$) ?

24

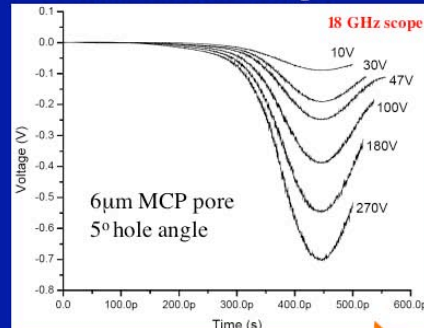

Rise time = $f(\text{pore size, } E_{\text{MCP-to-anode}}, E_{\text{Cathode-to-MCP}})$

(Photek Ltd. information)

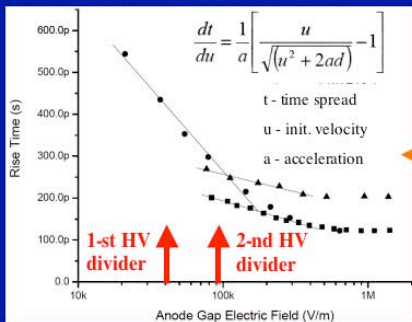

Pore size:

Cathode-to-MCP voltage:

MCP-to-anode electric field:

• Rise time is determined by:

- Transit time variation in MCP pores
Smaller MCP pore size, faster rise time
- Exit velocity variation from MCP towards anode
Larger MCP-to-Anode electric field, faster rise time
- Exit velocity variation from cathode towards MCP
Small effect for red wavelengths & Bialkali
[635 nm \Leftrightarrow ~ 2 eV $\Rightarrow dt/du|_{\text{max}} \sim ((2-\phi)/200) * 1000\text{ps}$],
 $\phi \sim 1.5-2$ eV. **Could be a problem for $\lambda < 300$ nm !!**

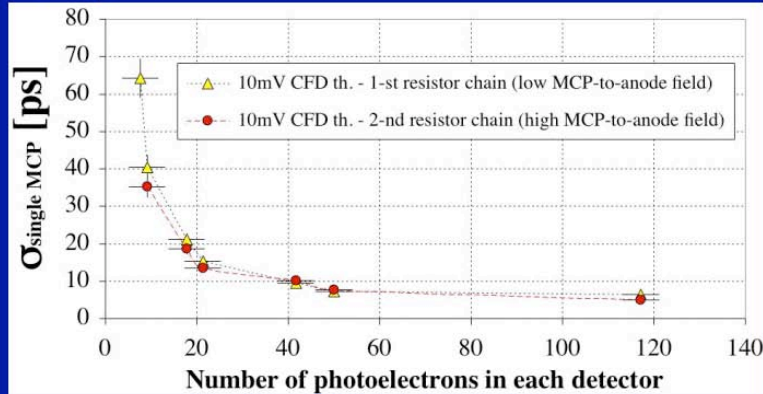

10/2/07

J. Va'vra, TOF vs. RICH, Trieste

26

A single MCP resolution = $f(N_{pe})_{MCP-to-anode\ field}$

Comparison of two resistor chains:

- Two Burle/Photonis MCP-PMTs with 10 μm MCP holes operating at 227 & 188 kV.
- Ortec 9327Amp/CFD (two) with a -10mV threshold and a walk threshold of +5mV & TAC566 & 14 bit ADC114

- **Some improvement when running a high MCP-to-anode field.**
- **Not worth the risks of a possible damage and reduction of the operating range for the magnetic field application.**

27

The best result with two TOF counters in tandem

Two detector resolution (resistor chain #2):

Each detector has $N_{pe} \sim 115-120 pe$:

$$\sigma_{single\ detector} \sim (1/\sqrt{2}) \sigma_{double\ detector} \sim 5.0\ ps$$

Running conditions:

- 1) Low MCP gain operation ($< 10^5$)
- 2) Linear operation
- 3) CFD discriminator
- 4) No additional ADC correction

- Two Burle/Photonis MCP-PMTs with 10 μm MCP holes operating at 2.85 & 2.43 kV.
- Ortec 9327Amp/CFD (two) with a walk th. of +5mV & TAC566 & 14 bit ADC11

Contribution of the MCP-PMT itself to the above single detector resolution:

$$\sigma_{MCP-PMT} < \sqrt{1/2 \{ \sigma^2 - [\sigma^2_{Pulser+TAC_ADC+Amp/CFD} - \sigma^2_{Pulser}] \}} < 4.5\ ps$$

7.0 ps
3.42 ps
< 2 ps (manufacturer)

Beam test - problem with the radiators

To make these pictures possible, send monitor signals over a long delay cable => rise time is degraded:

Beam test pulses:

Laser diode pulses (Npe ~50 pe):

- **A poor reflectivity of radiator's Al coating created a non-uniform number of photoelectrons. The 2-nd radiator's yield is worse than the 1-st one.**
- **One could still correct it if we would have a fast ADC !!**
(Ortec 9327 Amp/CFD provides a fast bipolar monitor of the amplifier. However, an ordinary ADC, such as LeCroy, would integrate it to a fixed constant. We did not have a better ADC available, which could be used to correct for the pulse height variation. If we would have it, we would get a better result.)
- $\sigma_{\text{single detector}} \sim (1/\sqrt{2}) \sigma_{\text{double detector}} \sim 22.6 \text{ ps}$

10/2/07

30

Conclusions

- Our present best laser diode results:
 - $\sigma_{\text{single MCP}} \sim 7.2 \text{ ps}$ for Npe ~ 50, expected from a 1cm thick radiator.
 - $\sigma_{\text{single MCP}} \sim 5.0 \text{ ps}$ for Npe ~ 120.
 - $\sigma_{\text{TTS}} \sim 27 \text{ ps}$ for Npe ~ 1.
 - **Electronics contribution (Amp, CFD, TAC, ADC):** $\sigma_{\text{Total_electronics}} \sim 3.4 \text{ ps}$.
 - **Upper limit on the MCP-PMT resolution:** $\sigma_{\text{MCP-PMT}} \sim 4.5 \text{ ps}$ (Npe ~120).
- Our present best test beam results:
 - $\sigma_{\text{single MCP}} \sim 22.5 \text{ ps}$ (believed to be due to a poor radiator Al-coating).
