The present analysis stems from the following experimental facts:
(1) The total cross sections $\pi N$ and $K N$ seem to converge to different asymptotic values, the difference being of the order of $3 \mathrm{mb} .{ }^{1}$
(2) The total cross sections of $\pi N$ and $\rho \mathrm{N}$ are comparable, whereas $\phi \mathrm{N}$ is smaller by more than a factor of $2 .{ }^{2}$
(3) $\frac{\sigma(\gamma p \rightarrow \phi p)}{\sigma(\gamma p \longrightarrow \rho p)}$ is smaller than the predicted $S U(3)$ ratio by about a factor of $15 ;{ }^{3}$ this discrepancy comes in fact from (2) as suggested by the vector mesons dominance of the electromagnetic current.

These facts can be partially explained by $\mathrm{SU}(3)$ breaking: for example, the quark model ${ }^{4}$ starts from (1) and explains (2) and (3).

In this letter the approach is different: $\mathrm{SU}(3)$ is assumed to be an exact symmetry for scattering amplitudes even at energies $10 \sim 20 \mathrm{GeV}$; the high energy behavior is given by exchanges in the $t$ channel, the main contribution coming from the Pomeranchon of which we want to determine the $\operatorname{SU}(3)$ assignment.

We make the general assumption that the Pomeranchon is a linear superposition of a singlet and an octet states with a mixing angle $\alpha$ :

$$
|\mathrm{P}\rangle=\left|\mathrm{P}_{1}\right\rangle \cos \alpha+\left|\mathrm{P}_{8}\right\rangle \sin \alpha
$$

Consequently the contribution of $P$ exchange to the forward elastic mesonnucleon scattering amplitudes is:

$$
\begin{aligned}
& A_{p}^{\pi}=\left(\cos \alpha+\frac{1}{\sqrt{2}} \sin \alpha\right) A_{p}^{(0)} \\
& A_{p}^{K}=\left(\cos \alpha-\frac{1}{2 \sqrt{2}} \sin \alpha\right) A_{p}^{(0)} \\
& A_{p}^{\rho}=A_{p}^{\omega}=\left(\cos \alpha+\frac{1}{\sqrt{2}} \sin \alpha\right) A_{p}^{(1)}
\end{aligned}
$$

$$
\mathrm{A}_{\mathrm{p}}^{\phi}=(\cos \alpha-\sqrt{2} \sin \alpha) \mathrm{A}_{\mathrm{p}}^{(1)}
$$

where ( 0 ), (1) stands for $0^{-}, 1^{-}$octets.
If we assume universality for the meson-meson-P coupling, we can derive the following conclusions that may be experimentally tested:

$$
\begin{aligned}
& \text { (1) } \lim _{\mathrm{S} \rightarrow \infty}\left\{\frac{\sigma_{\mathrm{T}}(\pi \mathrm{p})}{\sigma_{\mathrm{T}}(\mathrm{Kp})}\right\}=\frac{2 \sqrt{2}+2 \tan \alpha}{2 \sqrt{2}-\tan \alpha} \\
& \text { (2) } \lim _{\mathrm{s} \rightarrow \infty}\left\{\frac{\sigma_{\mathrm{T}}(\pi \mathrm{p})}{\sigma_{\mathrm{T}}(\rho \mathrm{p})}\right\}=1 \\
& \text { (3) } \lim _{\mathrm{s} \rightarrow \infty}\left\{\sigma_{\mathrm{T}}(\phi \mathrm{p})\right\}=\lim _{\mathrm{s} \rightarrow \infty}\left\{2 \sigma_{\mathrm{T}}(\mathrm{Kp})-\sigma_{\mathrm{T}}(\pi \mathrm{p})\right\}
\end{aligned}
$$

Let us now consider a finite $s$; in addition to $P$, one can exchange the $2^{+} I=0$ states $f$ and $f^{\prime}$ (we consider only the $t$ channel exchange of $I=0 C+$ particles). In analogy with the $1^{-}$octet, we suppose that $f, f^{\prime}$ are mixed with a mixing angle A $\tan \left(\frac{1}{\sqrt{2}}\right)$ as suggested by the quark model, in agreement with the mass formula and the production of $f^{1}$ in $\pi$ and $K-p$ interactions; this mixing angle and the hypothesis of universality of $2^{+}$mesons couplings leads to the property that $f^{\prime}$ does not couple to $\pi$ and nucleons: it therefore does not contribute to any $\sigma_{\mathrm{T}}$ (meson-N).

The meson-nucleon scattering amplitudes can then be written ( $\mathrm{I}=0 \mathrm{C}+\mathrm{ex}-$ changes):

$$
\begin{aligned}
& A_{\pi}=\left(\cos \alpha+\frac{1}{\sqrt{2}} \sin \alpha\right) A_{\mathrm{p}}+A_{\mathrm{f}} \\
& A_{\mathrm{K}}=\left(\cos \alpha-\frac{1}{2 \sqrt{2}} \sin \alpha\right) A_{\mathrm{p}}+\frac{1}{2} A_{\mathrm{f}}
\end{aligned}
$$

$$
\begin{aligned}
& A_{\rho}=A_{\omega}=A_{\pi} \\
& A_{\phi}=(\cos \alpha-\sqrt{2} \sin \alpha) A_{p}
\end{aligned}
$$

so that

$$
\begin{equation*}
A_{\phi}=2 A_{K}-A_{\pi} \tag{5}
\end{equation*}
$$

or
(4) $\sigma_{\mathrm{T}}\left(\phi_{\mathrm{p}}\right)=2 \sigma_{\mathrm{T}}(\mathrm{KN})-\sigma_{\mathrm{T}}(\pi \mathrm{p})$
where

$$
\begin{aligned}
& 4 \sigma_{\mathrm{T}}(\mathrm{KN})=\sigma_{\mathrm{T}}\left(\mathrm{~K}^{+} \mathrm{p}\right)+\sigma_{\mathrm{T}}\left(\mathrm{~K}^{-} \mathrm{p}\right)+\sigma_{\mathrm{T}}\left(\mathrm{~K}_{\mathrm{n}}^{+}\right)+\sigma_{\mathrm{T}}\left(\mathrm{~K}^{-} \mathrm{n}\right) \\
& 2 \sigma_{\mathrm{T}}(\mathrm{mp})=\sigma_{\mathrm{T}}\left(\pi^{+} \mathrm{p}\right)+\sigma_{\mathrm{T}}\left(\pi^{-} \mathrm{p}\right)
\end{aligned}
$$

We see that adding the assumptions of $f-f^{\prime}$ mixing angle and $2^{+}$universality has made our predictions (2) and (3) valid for any s (high enough so that s channel contributions are negligible); for (3), this fact is a pure accident since formula (3) is based only on P SU(3) assignment, and (4) on $P$ and $f \operatorname{SU}(3)$ assignments.

In Fig. 1 our results are compared with the experimental data; the assumption of universality is in good agreement with the experiment since $\sigma_{\mathrm{T}}(\rho \mathrm{p})$ is equal to $\sigma_{\mathrm{T}}(\mathrm{Tp})$ within the experimental error (even at the relatively low energy where $\sigma_{\mathrm{T}}(\rho \mathrm{p})$ has been measured), while $\sigma_{\mathrm{T}}(\phi \mathrm{p})$ seems to agree quite well with the combination $\left\{2 \sigma_{\mathrm{T}}(\mathrm{KN})-\sigma_{\mathrm{T}}(\pi \mathrm{p})\right\}$ which is shown to be constant with energy. Figure 1 also shows the prediction of the quark model for $\sigma_{\mathrm{T}}(\phi \mathrm{p})$ which should increase with energy (in this latter case the errors are smaller since the model involves only $K^{ \pm} p$ cross sections and not the less accurate $K^{ \pm} \cdot n$ cross sections). ${ }^{6}$

A sufficiently accurate measurement of $\sigma_{\mathrm{T}}(\phi \mathrm{p})$ in function of energy could choose between unbroken or broken $\mathrm{SU}(3)$ scattering theory; but experimentally this seems very difficult. Another important test would be to measure accurately the $K^{ \pm}$-proton and neutron cross sections.

To make quantitative predictions, one should assume an asymptotic behavior: using the Regge poles model, we can fit the experimental data on $\sigma_{\mathrm{T}}(\pi \mathrm{p}), \sigma_{\mathrm{T}}(\mathrm{KN})$ and the real part of the ( $\pi p$ ) elastic amplitude. In the familiar notation:

$$
\begin{aligned}
& \sigma_{\mathrm{T}}(\pi \mathrm{p})=\mathrm{A}_{\mathrm{p}}^{\pi}+\mathrm{A}_{\mathrm{f}}\left(\frac{\mathrm{E}}{\mathrm{E}_{0}}\right)^{\alpha_{\mathrm{f}}-1} \\
& \sigma_{\mathrm{T}}(\mathrm{KN})=\mathrm{A}_{\mathrm{p}}^{\mathrm{K}}+\frac{1}{2} \mathrm{~A}_{\mathrm{f}}\left(\frac{\mathrm{E}}{\mathrm{E}_{0}}\right)^{\alpha_{\mathrm{f}}-1} \\
& {\left[\frac{\operatorname{Re}(\pi \mathrm{p})}{\operatorname{mm}(\pi \mathrm{p})}\right]_{\mathrm{t}}=0} \\
& {\left[\mathrm{~A}_{\mathrm{p}}+\mathrm{A}_{\mathrm{f}}\left(\frac{\mathrm{E}}{\mathrm{E}_{0}}\right)^{\left.\alpha_{\mathrm{f}}-1\right] \tan \frac{\pi \alpha_{\mathrm{f}}}{2}}\right.} \\
& \mathrm{E}_{0}=1 \mathrm{GeV}
\end{aligned}
$$

The results of the fitting are shown in Fig。2 and Table I. We present two fits: In fit $1, \alpha$ is taken equal to 0 ( P unitary singlet) and the 3 parameters $A_{p}, A_{f}, \alpha_{f}$ are deduced; fit 2 investigates the possibility of $\left(P_{1}, P_{8}\right)$ mixing by fitting 4 parameters: $A_{p}^{\pi}, A_{p}^{K}, A_{f}, \alpha_{f}$. The results strongly favor different asymptotic limits for $\sigma_{\mathrm{T}}(\pi \mathrm{p})$ and $\sigma_{\mathrm{T}}(\mathrm{KN})$ with a mixing angle $\alpha=(10.5 \pm 2.0)^{\circ}$ 。 Obviously this value is dependent on the assumed Regge asymptotic behavior.

The author would like to thank Professor A. Blanc-Lapierre for his support and Professors W. K. H. Panofsky and R. F. Mozley for their hospitality at SLAC.
