(Dated: April 25, 2007)

Using 385 fb^{-1} of e^+e^- collisions, we study the amplitudes of the singly Cabibbo-suppressed decay $D^0 \rightarrow K^-K^+\pi^0$. We measure the strong phase difference between the \bar{D}^0 and D^0 decays to $K^*(892)^+K^-$ to be $-35.5^\circ \pm 1.9^\circ$ (stat) $\pm 2.2^\circ$ (syst), and their amplitude ratio to be 0.599 ± 0.013 (stat) ± 0.011 (syst). We observe contributions from the $K\pi$ and K^-K^+ scalar and vector amplitudes, and analyze their angular moments. We find no evidence for charged κ , nor for higher spin states. We also perform a partial wave analysis of the K^-K^+ system in a limited mass range.

PACS numbers: 13.25.Ft, 12.15.Hh, 11.30.Er

The amplitudes describing D meson weak-decays into three-body final states are dominated by intermediate resonances that lead to highly non-uniform intensity distributions in the available phase space. Analyses of these distributions have led to new insights into the role of the light-meson systems produced [1]. The $K^\pm\pi^0$ systems from the decay $D^0 \rightarrow K^-K^+\pi^0$ [2] can provide information on the $K\pi$ S -wave (spin-0) amplitude in the mass range 0.6 – 1.4 GeV/c^2 , and hence on the possible existence of the $\kappa(800)$, reported to date only in the neutral state ($\kappa^0 \rightarrow K^-\pi^+$) [3]. If the κ has isospin $1/2$, it should be observable also in the charged states. Results of the present analysis can be an input for extracting the CP -violating phase $\gamma = \arg(-V_{ud}V_{ub}^*/V_{cd}V_{cb}^*)$ of the quark mixing matrix by exploiting interference structure in the Dalitz plot from the decay $B^\pm \rightarrow D_{K^-K^+\pi^0}^0 K^\pm$ [4, 5]. Singly Cabibbo-suppressed decays are also important because they might be sensitive to direct CP violation in charm decays [6], the discovery of which might indicate physics beyond the Standard Model.

We perform the present analysis on 385 fb^{-1} of e^+e^- collision data collected at and around 10.58 GeV center-of-mass (CM) energy with the *BABAR* detector [7] at the PEP-II storage ring. We distinguish D^0 from \bar{D}^0 by reconstructing the decays $D^{*+} \rightarrow D^0\pi^+$ and $D^{*-} \rightarrow \bar{D}^0\pi^-$. The event-selection criteria are the same as those used in our measurement of the branching ratio of the decay $D^0 \rightarrow K^-K^+\pi^0$ [8]. In particular, we require that the CM momentum of the D^0 candidate be greater than $2.77 \text{ GeV}/c$, and that $|m_{D^{*+}} - m_{D^0} - 145.4| < 0.6 \text{ MeV}/c^2$, where m refers to a reconstructed invariant mass. In the signal region, $1855 < m_{D^0} < 1875 \text{ MeV}/c^2$, we find 11278 ± 110 signal events with a purity of about 98.1%. We estimate signal efficiency using simulated $D^0 \rightarrow K^-K^+\pi^0$ events from $c\bar{c}$ decays, generated uniformly in the available phase space, and subjected to the same selection procedure applied to the data.

Neglecting CP violation in D meson decays, we define the D^0 (\bar{D}^0) decay amplitude \mathcal{A} ($\bar{\mathcal{A}}$) in the $D^0 \rightarrow K^-K^+\pi^0$ Dalitz plot of Fig. 1, as:

$$\mathcal{A}[D^0 \rightarrow K^-K^+\pi^0] \equiv f_{D^0}(m_{K^+\pi^0}^2, m_{K^-\pi^0}^2), \quad (1)$$

$$\bar{\mathcal{A}}[\bar{D}^0 \rightarrow K^+K^-\pi^0] \equiv f_{D^0}(m_{K^-\pi^0}^2, m_{K^+\pi^0}^2). \quad (2)$$

The complex quantum mechanical amplitude f is a coherent sum of all relevant quasi-two-body $D^0 \rightarrow (r \rightarrow AB)C$ isobar model [9] resonances, $f = \sum_r a_r e^{i\phi_r} A_r(s)$. Here $s = m_{AB}^2$, and A_r is the resonance amplitude. We

obtain coefficients a_r and ϕ_r from a likelihood fit. The probability density function for signal events is $|f|^2$. We model incoherent background empirically using events from the lower sideband of the m_{D^0} [8] distribution.

For D^0 decays to spin-1 (P -wave) and spin-2 states, we use the Breit-Wigner amplitude,

$$A_{BW}(s) = \mathcal{M}_L(s, p) \frac{1}{M_0^2 - s - iM_0\Gamma(s)}, \quad (3)$$

$$\Gamma(s) = \Gamma_0 \left(\frac{M_0}{\sqrt{s}} \right) \left(\frac{p}{p_0} \right)^{2L+1} \left[\frac{\mathcal{F}_L(p)}{\mathcal{F}_L(p_0)} \right]^2, \quad (4)$$

where M_0 (Γ_0) is the resonance mass (width) [10], L is the angular momentum quantum number, p is the momentum of either daughter in the resonance rest frame, and p_0 is the value of p when $s = M_0^2$. The function \mathcal{F}_L is the Blatt-Weisskopf barrier factor [11]: $\mathcal{F}_0 = 1$, $\mathcal{F}_1 = 1/\sqrt{1 + Rp^2}$, and $\mathcal{F}_2 = 1/\sqrt{9 + 3Rp^2 + Rp^4}$, where we take the meson radial parameter R to be 1.5 GeV^{-1} [12]. We define the spin part of the amplitude, \mathcal{M}_L , as: $\mathcal{M}_0 = M_{D^0}^2$, $\mathcal{M}_1 = -2 \vec{p}_A \cdot \vec{p}_C$, and $\mathcal{M}_2 = \frac{4}{3} [3(\vec{p}_A \cdot \vec{p}_C)^2 - |\vec{p}_A|^2 \cdot |\vec{p}_C|^2] M_{D^0}^{-2}$, where M_{D^0} is the nominal D^0 mass, and \vec{p}_i is the 3-momentum of particle i in the resonance rest frame.

For D^0 decays to $K^\pm\pi^0$ S -wave states, we consider three amplitude models. One model uses the LASS amplitude for $K^-\pi^+ \rightarrow K^-\pi^+$ elastic scattering [13],

$$A_{K\pi(S)}(s) = \frac{\sqrt{s}}{p} \sin \delta(s) e^{i\delta(s)}, \quad (5)$$

$$\delta(s) = \cot^{-1} \left(\frac{1}{pa} + \frac{bp}{2} \right) + \cot^{-1} \left(\frac{M_0^2 - s}{M_0 \Gamma_0 \cdot \frac{M_0}{\sqrt{s}} \cdot \frac{p}{p_0}} \right), \quad (6)$$

where M_0 (Γ_0) refers to the $K_0^*(1430)$ mass (width), $a = 1.95 \pm 0.09 \text{ GeV}^{-1}c$, and $b = 1.76 \pm 0.36 \text{ GeV}^{-1}c$. The unitary nature of Eq. 5 provides a good description of the amplitude up to $1.45 \text{ GeV}/c^2$ (i.e., $K\eta'$ threshold). In Eq. 6, the first term is a non-resonant contribution defined by a scattering length a and an effective range b , and the second term represents the $K_0^*(1430)$ resonance. The phase space factor \sqrt{s}/p converts the scattering amplitude to the invariant amplitude. Our second model uses the E-791 results for the $K^-\pi^+$ S -wave amplitude from an energy-independent partial wave analysis in the decay $D^+ \rightarrow K^-\pi^+\pi^+$ [14]. The third model uses a coherent sum of a uniform non-resonant term, and Breit-Wigner terms for the $\kappa(800)$ and $K_0^*(1430)$ resonances.

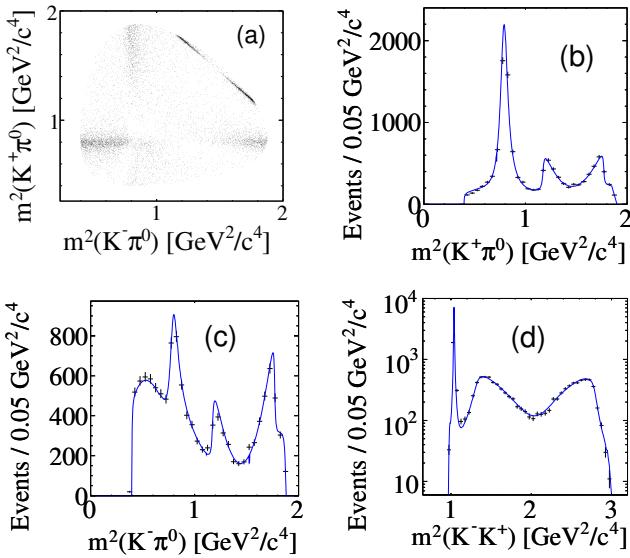

FIG. 1: (Color online) Dalitz plot for $D^0 \rightarrow K^- K^+ \pi^0$ [2] data (a), and the corresponding squared invariant mass projections (b–d). The three-body invariant mass of the D^0 candidate is constrained to the nominal value. In plots (b–d), the dots (with error bars, black) are data points and the solid lines (blue) correspond to the best isobar fit models.

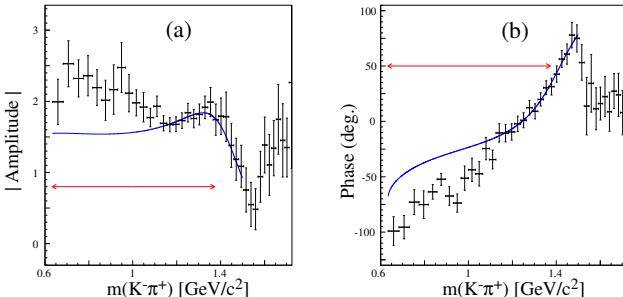

FIG. 2: (Color online) LASS (solid line, blue) and E-791 (dots with error bars) $K\pi$ S-wave amplitudes (a), in arbitrary units, and phase (b). The double headed arrow (red) indicates the mass range available in the decay $D^0 \rightarrow K^- K^+ \pi^0$.

In Fig. 2 we compare the $K\pi$ S-wave amplitude from the E-791 analysis [14] to the LASS amplitude of Eqs. 5–6. For easy comparison, we have normalized the LASS amplitude in Fig. 2a approximately to the E-791 measurements with $\sqrt{s} > 1.15$ GeV/c², and have reduced the LASS phase, $\delta(s)$, in Fig. 2b by 80°. We then observe good agreements in the mass dependence of amplitude and phase for $\sqrt{s} > 1.15$ GeV/c². As the mass decreases from 1.15 GeV/c², the E-791 amplitude increases while the LASS amplitude decreases, with the ratio finally reaching ~ 1.7 at threshold. At the same time, their phase difference increases to $\sim 40^\circ$ at threshold. This be-

havior might be due to the form factor describing D^0 decay to a $K\pi$ S-wave system and a bachelor \bar{K} . Since no centrifugal barrier is involved, such an effect should be more significant for S-wave than for higher spin waves because of the larger overlap between the initial and final state wave functions. However, the inverse momentum of the $K\pi$ system in the D^0 rest frame increases from 0.27 Fermi at $K\pi$ threshold to 0.48 Fermi at 1.15 GeV/c², therefore any form factor effect would decrease with increasing $K\pi$ mass. If the effect is essentially gone by 1.15 GeV/c², similar mass dependence of amplitude and phase in D^0 decay and $K\pi$ scattering would be observable at higher mass values, in agreement with Fig. 2. In the present analysis, we make an attempt to distinguish between the two rather different $K\pi$ S-wave mass dependences in the region below ~ 1.15 GeV/c². In each case, we also allow the fit to determine the strength and phase of these amplitudes relative to the $K^*(892)^+$ reference.

We describe the D^0 decay to a $K^- K^+$ S-wave state by a coupled-channel Breit-Wigner amplitude for the $f_0(980)$ and $a_0(980)$ resonances, with their respective couplings to $\pi\pi$, KK and $\eta\pi$, $K\bar{K}$ final states [15],

$$A_{f_0[a_0]}(s) = \frac{M_{D^0}^2}{M_0^2 - s - i(g_1^2 \rho_{\pi\pi[\eta\pi]} + g_2^2 \rho_{K\bar{K}})}. \quad (7)$$

Here ρ represents Lorentz invariant phase space, $2p/\sqrt{s}$. For the $f_0(980)$, we use the BES [16] parameter values $M_0 = 965 \pm 10$ MeV/c², $g_1^2 = 165 \pm 18$ MeV²/c⁴, and $g_2^2/g_1^2 = 4.21 \pm 0.33$. For the $a_0(980)$, we use the Crystal Barrel [17] values $M_0 = 999 \pm 2$ MeV/c², $g_1 = 324 \pm 15$ MeV/c², and $g_1^2/g_2^2 = 1.03 \pm 0.14$. Only the high mass tails of $f_0(980)$ and $a_0(980)$ are observable, as shown in Fig. 3a. They are similar, so we try a model for each as a description of the $K^- K^+$ S-wave amplitude. In Fig. 3b we show, in the same mass range, the $K^- K^+$ P-wave amplitude parametrized by the $\phi(1020)$ meson.

To fit the Dalitz plot, we try several models incor-

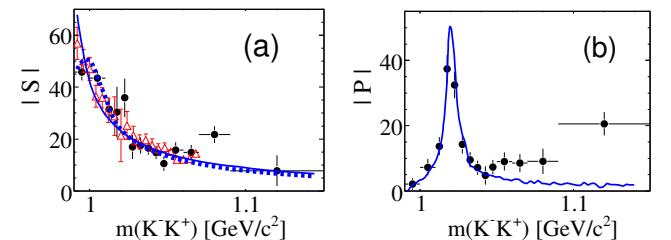

FIG. 3: (Color online) The phase-space-corrected $K^- K^+$ S- and P-wave amplitudes, $|S|$ and $|P|$ respectively, in arbitrary units, as functions of the invariant mass. (a) Lineshapes for (solid line, blue) $f_0(980)$, and (broken line, blue) $a_0(980)$, derived from Eq. 7. (b) Lineshape for $\phi(1020)$ (solid line, blue). In each plot, solid circles with error bars correspond to values obtained from the model-independent analysis for $|S|$ and $|P|$ using Eq. 8. In (a), the open triangles (red) correspond to values obtained from the decay $D^0 \rightarrow K^- K^+ \bar{K}^0$ (see text).

TABLE I: The results obtained from the $D^0 \rightarrow K^- K^+ \pi^0$ Dalitz plot fit. We define amplitude coefficients, a_r and ϕ_r , relative to those of the $K^*(892)^+$. The errors are statistical and systematic, respectively. We show the $a_0(980)$ contribution, when it is included in place of the $f_0(980)$, in square brackets. We denote the $K\pi$ S -wave states here by $K^\pm \pi^0(S)$. We use LASS amplitude to describe the $K\pi$ S -wave states in both the isobar models (I and II).

porating various combinations of intermediate states. In each fit, we include the $K^*(892)^+$ and measure the complex amplitude coefficients of other states relative to it. As a check on the quality of each fit, we compare the number of events observed in bins in the Dalitz plot with the number predicted by the fit. We compute residuals and statistical uncertainties to form a χ^2 , and take χ^2/ν (where ν is the number of bins less number of variable parameters) as a figure of merit. We also compare the distributions of angular moments (described later) predicted by the fit and actually observed in the data.

The LASS $K\pi$ S -wave amplitude gives the best agreement with data and we use it in our nominal fits (see next paragraph). The $K\pi$ S -wave modeled by the combination of $\kappa(800)$ (with parameters taken from Ref. [3]), a non-resonant term and $K_0^*(1430)$ has a smaller fit probability (χ^2 probability $< 5\%$). The best fit with this model (χ^2 probability 13%) yields a charged κ of mass (870 ± 30) MeV/ c^2 , and width (150 ± 20) MeV/ c^2 , significantly different from those reported in Ref. [3] for the neutral state. This does not support the hypothesis that production of a charged, scalar κ is being observed. The E-791 amplitude [14] describes the data well, except near threshold (χ^2 probability 23%). Though our data favor the LASS parametrization for $\sqrt{s} < 1.15$ GeV/ c^2 , the insensitivity of the fit to small variations in amplitude at these masses does not allow an independent S -wave measurement with the present data sample. Therefore, we use the E-791 amplitude to estimate systematic uncertainty in our results.

We find that two different isobar models describe the data well. Both yield almost identical behavior in invariant mass (Fig. 1b–1d) and angular distribution (Fig. 4). We use LASS amplitude to describe the $K\pi$ S -wave amplitudes in both the isobar models (I and II). We summarize the results of the best fits (Model-I: $\chi^2/\nu = 702.08/714$, probability 61.9%; Model-II: $\chi^2/\nu = 718.89/717$, probability 47.3%) in Table I. We also list

the fit fraction for each resonant process r , defined as $f_r \equiv \int |a_r A_r|^2 d\tau / \int |f_{D^0}|^2 d\tau$, where $d\tau = dm_{K^- \pi^0}^2 dm_{K^+ \pi^0}^2$, in Table I. Due to interference among the contributing amplitudes, the f_r do not sum to one in general. We find that the $K\pi$ S -wave is not in phase with the P -wave at threshold as it was in the LASS scattering data. For Model-I (II), the S -wave phase relative to the $K^*(892)^+$ is $\sim 180^\circ$ (150°) for the positive charge and 135° (110°) for the negative charge.

We have also considered the possible contributions from other resonant states such as: $K_2^*(1430)$, $f_2(1270)$, $f_0(1370)$, and $f_0(1510)$. We find that none of them is needed to describe the Dalitz plot, they all provide small contributions and lead to smaller χ^2 probabilities.

Angular distributions provide a more detailed information on specific features of the amplitudes used in the description of the Dalitz plot. We define the helicity angle θ_H for the decay $D^0 \rightarrow (r \rightarrow AB)C$ as the angle between the momentum of A in the AB rest frame and the momentum of AB in the D^0 rest frame. The moments of $\cos \theta_H$, defined as the efficiency-corrected and background-subtracted invariant mass distributions of events weighted by spherical harmonic functions, $Y_l^0(\cos \theta_H) = \sqrt{\frac{2l+1}{4\pi}} P_l(\cos \theta_H)$, where the P_l are Legendre polynomials of order l , are shown in Fig. 4 for the $K^+ \pi^0$ and $K^- K^+$ channels, for $l = 0 - 7$. The $K^- \pi^0$ moments are similar to those for $K^+ \pi^0$.

The mass dependent $K^- K^+$ S - and P -wave complex amplitudes can also be obtained directly from our data in a model independent way in a limited mass range around 1 GeV/ c^2 . In a region of the Dalitz plot where S - and P -waves in a single channel dominate, their amplitudes are given by the following Legendre polynomial moments,

$$P_0 = \frac{|S|^2 + |P|^2}{\sqrt{2}}, \quad P_1 = \sqrt{2} |S| |P| \cos \theta_{SP}, \quad P_2 = \sqrt{\frac{2}{5}} |P|^2, \quad (8)$$

using $\int_{-1}^1 P_l P_m d(\cos \theta_H) = \delta_{lm}$. Here $|S|$ and $|P|$ are, respectively, the magnitudes of the S - and P -wave am-

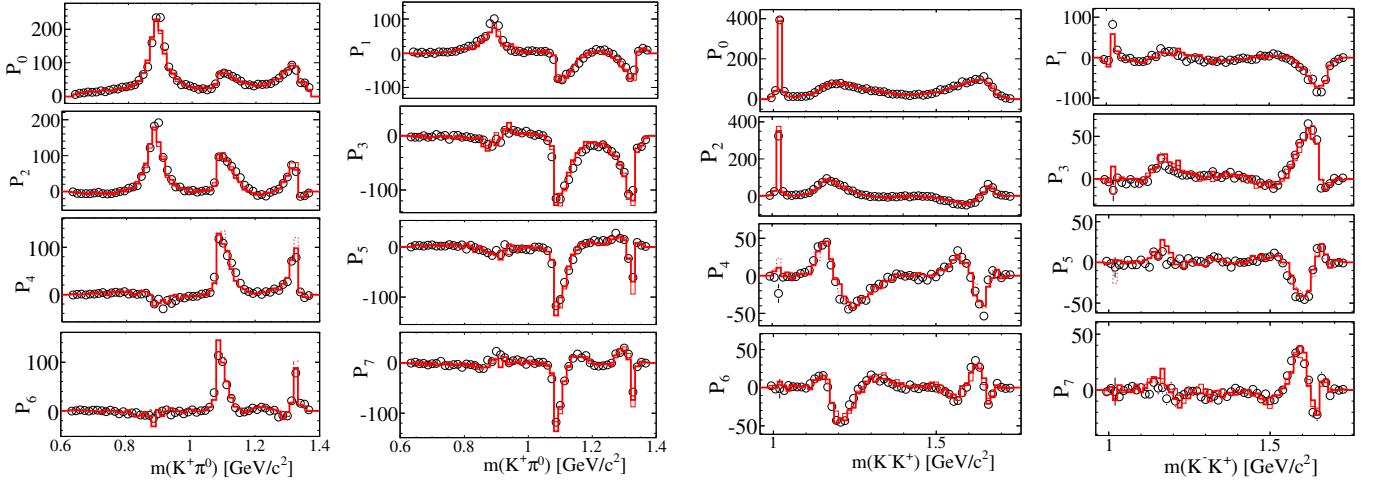

FIG. 4: (Color online) The mass dependence of the spherical harmonic moments of $\cos \theta_H$ after efficiency corrections and background subtraction: $K^+\pi^0$ (columns I, II) and K^-K^+ (columns III, IV). The circles with error-bars are data points and the curves (red) are derived from the fit functions (see text). For the sake of visibility, we do not show error bars on the curves.

plitudes, and $\theta_{SP} = \theta_S - \theta_P$ is the relative phase between them. We use these relations to evaluate $|S|$ and $|P|$, shown in Fig. 3, for the K^-K^+ channel in the mass range $m_{K^-K^+} < 1.15$ GeV/ c^2 . The measured values of $|S|$ agree well with those obtained in the analysis of the decay $D^0 \rightarrow K^-K^+K^0$ [18]. They also agree well with either the $f_0(980)$ or the $a_0(980)$ lineshape. The measured values of $|P|$ are consistent with a Breit-Wigner lineshape for $\phi(1020)$. Results for $\cos \theta_{SP}$ and θ_{SP} are shown in Figs. 5a–5b. A two-fold ambiguity in the sign of θ_{SP} exists, as shown in Fig. 5b. It is, however, straightforward to choose the physical solution. In this region, the $\phi(1020)$ meson (P -wave) has a very rapidly rising phase, while we expect the S -wave phase to be relatively slowly varying. Thus, the upper solution, in which $\theta_S - \theta_P$ is rapidly falling, is the physical solution. We take the Breit-Wigner phase of $\phi(1020)$, shown in Fig. 5c, to be a good model for θ_P and obtain θ_S , as plotted in Fig. 5d. These results show little variation in S -wave phase up to about 1.02–1.03 GeV/ c^2 , then a rapid rise above that. Also, in Fig. 3b, we observe that $|P|$ follows the $\phi(1020)$ curve well up to about the same mass, with a significant deviation above that. The behavior observed matches well to that obtained from the isobar model I or II. No distinction between them appears possible from this analysis. The partial wave analysis described above is valid, in the absence of higher spin states, only if no interference occurs from the crossing $K\pi$ channels. The behavior observed in both S - and P -waves above ~ 1.03 GeV/ c^2 can, therefore, be attributed to high mass tails of the $K^*(892)$ and low mass tails of possible higher K^* resonances.

Systematic uncertainties in quantities in Table I arise from experimental effects, and also from uncertainties in the nature of the models used to describe the data. We determine these separately and add them in quadrature. In both cases, we assign the maximum deviation

in the observed quantities (i.e., a_r , ϕ_r , and f_r) from the central value as a systematic uncertainty, taking correlations among fit-parameters into account. We characterize the uncertainties due to $K\pi$ S -wave amplitudes and resonance mass-width values as model dependent. We estimate them from the variation that results when either the LASS amplitude in the fit is replaced by the E-791 amplitude, or the resonance parameters are changed by one standard deviation (σ). Similarly, we estimate the experimental uncertainty from the variation in result when either the signal efficiency parameters are varied by 1σ , or the background shape is taken from simulation instead of the data sideband, or the ratio of particle-identification rates in data and simulation is varied by 1σ . Model and experimental systematics contribute almost equally to the total uncertainty.

Neglecting CP violation, the strong phase difference, δ_D , between the \bar{D}^0 and D^0 decays to $K^*(892)^+K^-$ state and their amplitude ratio, r_D , are given by

$$r_D e^{i\delta_D} = \frac{a_{D^0 \rightarrow K^*+K^-}}{a_{D^0 \rightarrow K^*+K^-}} e^{i(\delta_{K^*-K^+} - \delta_{K^*+K^-})}. \quad (9)$$

Combining the results of models I and II, we find $\delta_D = -35.5^\circ \pm 1.9^\circ$ (stat) $\pm 2.2^\circ$ (syst) and $r_D = 0.599 \pm 0.013$ (stat) ± 0.011 (syst). These results are consistent with the previous measurements [19], $\delta_D = -28^\circ \pm 8^\circ$ (stat) $\pm 11^\circ$ (syst) and $r_D = 0.52 \pm 0.05$ (stat) ± 0.04 (syst).

In conclusion, we have studied the amplitude structure of the decay $D^0 \rightarrow K^-K^+\pi^0$, and measured δ_D and r_D . We find that two isobar models give excellent descriptions of the data. Both models include significant contributions from $K^*(892)$, and each indicates that $D^0 \rightarrow K^*+K^-$ dominates over $D^0 \rightarrow K^*-K^+$. This suggests that, in tree-level diagrams, the form factor for D^0 coupling to K^{*-} is suppressed compared to the corresponding K^- coupling. While the measured fit-fraction

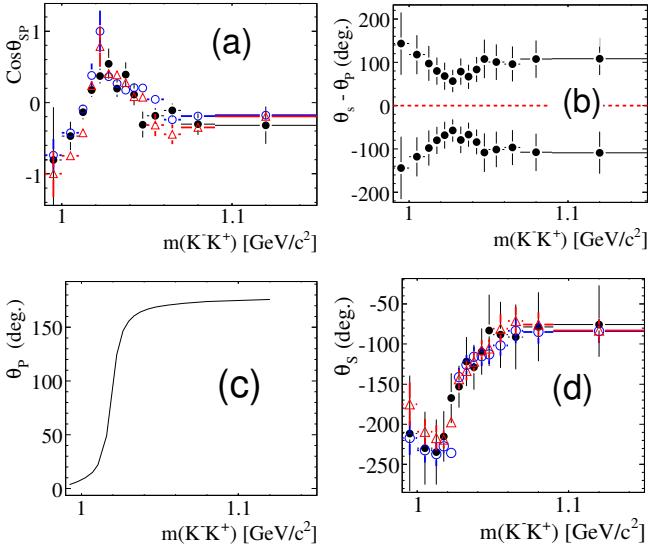

FIG. 5: (Color online) Results of the partial-wave analysis of the K^-K^+ system using Eq. 8 described in the text. (a) Cosine of relative phase $\theta_{SP} = \theta_S - \theta_P$, (b) two solutions for θ_{SP} , (c) P -wave phase taken from Eqs. 3–4 for the $\phi(1020)$ meson, and (d) S -wave phase derived from the upper solution in (b). Solid bullets are data points, and open circles (blue) and open triangles (red) correspond, respectively, to isobar models I and II. The number of simulated events used for the two models is 10 times larger than data. Errors for quantities from the isobar models arise from Monte Carlo statistical limitations, and differ from errors derived from Eq. 8.

for $D^0 \rightarrow K^{*+}K^-$ agrees well with a phenomenological prediction [20] based on a large SU(3) symmetry breaking, the corresponding results for $D^0 \rightarrow K^{*-}K^+$ and the color-suppressed $D^0 \rightarrow \phi\pi^0$ decays differ significantly from the predicted values. It appears from Table I that the $K^+\pi^0$ S -wave amplitude can absorb any $K^*(1410)$ and $f'_2(1525)$ if those are not in the model. The other components are quite well established, independent of the model. The $K\pi$ S -wave amplitude is consistent with that from the LASS analysis, throughout the available mass range. We cannot, however, completely exclude the behavior at masses below ~ 1.15 GeV/ c^2 observed in the decay $D^+ \rightarrow K^-\pi^+\pi^+$ [3, 14]. The K^-K^+ S -wave amplitude, parametrized as either $f_0(980)$ or $a_0(980)^0$, is required in both isobar models. No higher mass f_0 states are found to contribute significantly. In a limited mass range, from threshold up to 1.02 GeV/ c^2 , we measure this amplitude using a model independent partial wave analysis. Agreement with similar measurements from $D^0 \rightarrow K^-K^+\bar{K}^0$ decay [18], and with the isobar models considered here, is excellent.

We are grateful for the excellent luminosity and machine conditions provided by our PEP-II colleagues, and for the substantial dedicated effort from the computing
