# PHOTON AMPLITUDES PREDICTED BY THE TRANSFORMATION BETWEEN CURRENT AND CONSTITUENT QUARKS* 

Frederick J. Gilman and Inga Karliner
Stanford Linear Accelerator Center Stanford University, Stanford, Calif. 94305

#### Abstract

The transformation between current and constituent quarks is discussed as it applies to real photon transitions. The general algebraic structure of such transitions is presented, and a resulting set of selection rules is derived. Many specific amplitudes for both mesons and baryons are worked out, and both their magnitudes and signs are compared with available experimental data.

## I. INTRODUCTION

A complete knowledge of the nature of the transformation from constituent to current quark states, together with the identification of the observed hadrons with simple (constituent) quark model states, would permit one to calculate all current induced transitions between hadrons. A major step in this direction has been taken by Melosh ${ }^{1}$ who was able to formulate and explicitly calculate such a transformation in the free quark model. While the details of such a transformation certainly depend on strong interaction dynamics, it is possible that certain general algebraic properties of the transformation abstracted from the free quark model may hold in Nature.

We shall assume that such a transformation does indeed exist, and that some of its algebraic properties can be abstracted from the free quark model. For the case of the axial-vector charge, the many consequences of this for pion transitions have already been extensively worked out and compared with experiment. ${ }^{2,3}$ Here we report the results for real $\left(q^{2}=0\right)$ photon transitions.

In the next section we present the origin and the basic properties of the theory along with the assumptions involved in applying it to actual hadrons. The general algebraic structure of photon amplitudes is discussed, as well as the method of calculating specific matrix elements. We derive a set of selection rules which include, and generalize, the old result ${ }^{4}$ that the transition from the nucleon to 3-3 resonance should be magnetic dipole in character. This general discussion of the theory is completed by a comparison with other theories with a related algebraic structure.

In Section III the photon transitions between meson states are detailed, along with a comparison of the predictions with the available experimental data. Then we turn to a detailed exposition of baryon electromagnetic transition
amplitudes in Section IV. A comparison of the predicted amplitudes with experiment, in both their magnitude and sign, is found in Section V. The signs are testable through a multipole analysis of pion photoproduction $\gamma \mathrm{N} \rightarrow \mathrm{N}^{*} \rightarrow \pi \mathrm{~N}$, where the signs of the previously calculated pion decay amplitudes ${ }^{2,3}$ also come into play. As reported in a previous paper, ${ }^{5}$ consistency of experiment and theory is found, including agreement with the relative signs of pion decay amplitudes obtained from analyzing $\pi \mathrm{N} \rightarrow \mathrm{N}^{*} \rightarrow \pi \Delta$. A summary and some conclusions are found in Section VI. The general outlook is very good, encouraging further study of the underlying dynamics and the extension to the $q^{2} \neq 0$ region.

## II. PHOTON AMPLITUDES AND THE TRANSFORMATION FROM CURRENT TO CONSTITUENT QUARKS

As we shall be concerned with current induced transitions between hadrons, let us first consider the algebra formed by the 16 vector and axial-vector charges, $Q^{\alpha}(t)$ and $Q_{5}^{\alpha}(t)$, which are simply integrals over all space of the time components of the corresponding currents measurable in weak and electromagnetic interactions:

$$
\begin{align*}
& Q^{\alpha}(t)=\int d^{3} x V_{0}^{\alpha}(\vec{x}, t)  \tag{1a}\\
& Q^{\alpha}(t)=\int d^{3} \times A_{0}^{\alpha}(\vec{x}, t) \tag{1b}
\end{align*}
$$

Here $\alpha$ is an $\operatorname{SU}(3)$ index which runs from 1 to 8 . At equal times these charges commute to form the algebra abstracted from the quark model by Gell-Mann, ${ }^{6}$

$$
\begin{align*}
& {\left[Q^{\alpha}(\mathrm{t}), \mathrm{Q}^{\beta}(\mathrm{t})\right]=\text { if }^{\alpha \beta \gamma} \mathrm{Q}^{\gamma}(\mathrm{t})}  \tag{2a}\\
& {\left[\mathrm{Q}^{\alpha}(\mathrm{t}), \mathrm{Q}^{\beta}(\mathrm{t})\right]=\text { if }^{\alpha \beta \gamma} \mathrm{Q}_{5}^{\gamma}(\mathrm{t})}  \tag{2b}\\
& {\left[\mathrm{Q}_{5}^{\alpha}(\mathrm{t}), \mathrm{Q}_{5}^{\beta}(\mathrm{t})\right]=\text { if }^{\alpha \beta \gamma}{ }_{\mathrm{Q}}{ }^{\gamma}(\mathrm{t})} \tag{2c}
\end{align*}
$$

This is the algebra of chiral $\operatorname{SU}(3) \times \operatorname{SU}(3)$, for it can be easily shown that Eqs. (2) are equivalent to the statement that the right-handed charges, $Q^{\alpha}+Q_{5}^{\alpha}$, and the left-handed charges, $Q^{\alpha}-Q_{5}^{\alpha}$, each form an $\operatorname{SU}(3)$, and that they commute with each other - hence, chiral $\operatorname{SU}(3) \times \operatorname{SU}(3)$. For $\alpha=1,2,3$ the $\mathrm{Q}^{\alpha{ }_{\prime}} \mathrm{s}$ are the generators of isospin rotations; for $\alpha=1, \ldots, 8$, they are the generators of SU(3). The last of Eqs. (2), sandwiched between nucleon states moving at infinite momentum in the $z$ direction, yields the Adler-Weisberger sum rule. ${ }^{7}$

Taken between states at infinite momentum, ${ }^{8}$ the $Q^{\alpha \rho_{s}}$ and $Q_{5}^{\alpha \prime_{s}}$ are "good" operators, i. $e_{0}$, they have finite (generally non-vanishing) values as $p_{z} \rightarrow \infty$ 。 These values are the same as those of space integrals over the z components of the respective currents. If we adjoin to the integrals of the time component of the vector currents and the z -component of the axial-vector currents (which commute like $\frac{\lambda^{\alpha}}{2}$ and $\frac{\lambda^{\alpha}}{2} \sigma_{z}$ ), integrals over certain "good" tensor current densities, the $\operatorname{SU}(3) \times \operatorname{SU}(3)$ algebra between states at infinite momentum can be enlarged still further. Letting the index $\alpha$ correspond to an $\operatorname{SU}(3)$ singlet when $\alpha=0$, we have 36 charges which commute like the products of $\mathrm{SU}(3)$ and Dirac matrices: $\frac{\lambda^{\alpha}}{2}, \frac{\lambda^{\alpha}}{2} \beta \sigma_{\mathrm{x}}, \frac{\lambda^{\alpha}}{2} \beta \sigma_{\mathrm{y}}$, and $\frac{\lambda^{\alpha}}{2} \sigma_{\mathrm{z}}$, where $\alpha-0,1, \ldots, 8$. These act as an identity operator plus an $\operatorname{SU}(6){ }_{W}$ algebra of 35 generators. We refer to this algebra, introduced by Dashen and Gell-Mann ${ }^{9}$ in 1965, as the $\operatorname{SU}(6)_{W}$ of currents. We denote these generators collectively by $\mathrm{F}^{\mathrm{i}}$, and use them to label the transformation properties of our states and operators. Note that $\beta \sigma_{\mathrm{x}}, \beta \sigma_{\mathrm{y}}$ and $\sigma_{\mathrm{z}}$, which commute with z boosts and are "good" operators, are not the same as the spin components $\sigma_{\mathrm{x}}, \sigma_{\mathrm{y}}$ and $\sigma_{\mathrm{z}}$. The appropriate algebra to use is that of $\mathrm{SU}\left({ }^{(6)} \mathrm{W}\right.$ and not $\mathrm{SU}(6)$ 。For quarks, $\beta=+1$ and quark spin and "W-spin" are the same; but for antiquarks, $\beta=-1$, we have $-\sigma_{\mathrm{x}},-\sigma_{\mathrm{y}}$ and $\sigma_{\mathrm{z}}$ instead of the antiquark spin components $\sigma_{\mathrm{x}}, \sigma_{\mathrm{y}}$ and $\sigma_{\mathrm{z}}{ }^{\circ}$

In what follows we will label states and operators by their transformation properties under this $\mathrm{SU}(6)_{\mathrm{W}}$ algebra of currents. For this purpose we shall often use just the $\operatorname{SU}(3) \times \operatorname{SU}(3)$ subalgebra of the whole $\mathrm{SU}(6)_{\mathrm{W}}$ algebra of currents, as this subalgebra has elements which are known to be directly measurable in weak and electromagnetic interactions. The overall $\mathrm{SU}(6)_{\mathrm{W}}$ representation will either be obvious or be made explicit. We will write

$$
\left\{(\mathrm{A}, \mathrm{~B})_{\mathrm{S}_{\mathrm{z}}}, \mathrm{~L}_{\mathrm{z}}\right\}
$$

where $A$ is the $\operatorname{SU}(3)$ representation under $Q^{\alpha}+Q_{5}^{\alpha}$, B the representation under $Q^{\alpha}-Q_{5}^{\alpha}$, and $S_{z}$ is the eigenvalue of $Q_{5}^{o}$, the singlet axial-vector charge ${ }^{10}$ The quantity $L_{z}$ is then defined in terms of the $z$ component of the total angular momentum $J$, as $L_{z}=J_{z}-S_{z}$. The "ordinary" $\operatorname{SU}(3)$ content (under $Q^{\alpha}$ ) of such a representation is just that of the direct product $\mathrm{A} \times \mathrm{B}$.

All representations of chiral $\operatorname{SU}(3) \times \operatorname{SU}(3)$ can be built up from $(3,1) 1 / 2$, $(1,3)_{-1 / 2},(1, \overline{3})_{1 / 2}$ and $(\overline{3}, 1){ }_{-1 / 2}$ which we define to be the current quark and current antiquark states with spin projection $\pm 1 / 2$ in the $z$ direction. The quarks form a 6 and the antiquarks a $\overline{6}$ in the full $\mathrm{SU}(6)_{\mathrm{W}}$ of currents.

Consider next combining three current quarks to form a baryon. If we take $L_{Z}=0$ and a symmetrical quark wave function, then we find the states with net $\operatorname{spin} S=1 / 2$ and $S=3 / 2$ transform as:

$$
\begin{array}{ll}
S=3 / 2, S_{z}=3 / 2: & \left\{(10,1)_{3 / 2}, 0\right\} \\
S=3 / 2, S_{z}=1 / 2: & \left\{(6,3)_{1 / 2}, 0\right\} \\
S=1 / 2, S_{z}=1 / 2: & \left\{(6,3)_{1 / 2}, 0\right\} \\
S=1 / 2, S_{z}=-1 / 2: & \left\{(3,6)_{-1 / 2}, 0\right\} \\
S=3 / 2, S_{z}=-1 / 2: & \left\{(3,6)_{-1 / 2}, 0\right\} \\
S=3 / 2, S_{z}=-3 / 2: & \left\{(1,10)_{-3 / 2}, 0\right\}
\end{array}
$$

and they all lie in a 56 of the full $\mathrm{SU}(6)_{\mathrm{W}}$ of currents. In particular, if a nucleon at infinite momentum with $J_{z}=1 / 2$ acted under the algebra of currents as if it were simply composed of two current quarks with $S_{z}=1 / 2$ and one current quark with $S_{z}=-1 / 2$ in a symmetrical wave function, we would have

$$
\begin{equation*}
|N\rangle=\mid \underline{56},\left\{(6,3)_{1 / 2}, 0\right\}> \tag{3}
\end{equation*}
$$

However, the $\operatorname{SU}(3)$ content of $(6,3)_{1 / 2}$ is just that of an octet (including the nucleon) and decuplet (including the $\Delta(1236)$ ). Since $Q_{5}^{\alpha}$ is a generator of $\mathrm{SU}(3) \times \mathrm{SU}(3)$, it can only connect this representation to itself, $\mathrm{i}_{\mathrm{\circ}} \mathrm{e}_{\mathrm{\circ}}$, for $\alpha=1$, 2,3 it can only connect the nucleon to the nucleon or to the $\Delta(1236)$. Furthermore, such a classification of the nucleon gives $\mathrm{g}_{\mathrm{A}}=5 / 3$. Both these results are in glaring contradiction with experiment. The nucleon cannot be in such a simple representation. This is already apparent from the Adler-Weisberger sum rule ${ }^{7}$ itself, for it shows that the nucleon is connected by a generator of the algebra of currents, the axial-vector charge $Q_{5}^{\alpha}$ (in the guise of the pion field) to many higher mass $\mathrm{N}^{*}$ 's. Thus the nucleon and these $\mathrm{N}^{*}$ 's must be in the same representation of $\mathrm{SU}(3) \times \mathrm{SU}(3)$ 。 Conversely, the nucleon state must span many different representations ${ }^{11}$ of the $\operatorname{SU}(3) \times \operatorname{SU}(3)$ and $\operatorname{SU}(6){ }_{W}$ of currents.

Therefore physical hadron states like the nucleon are not simple in terms of current quarks, i.e., they are not in the irreducible representations (I.R.) of the $\operatorname{SU}(6)_{W}$ of currents prescribed by the naive construction of baryons out of three current quarks (or out of quark-antiquark for mesons). As the next simplest possibility, let us assume instead that there exists a unitary operator, V, which transforms an irreducible representation (I.R.) of the algebra of currents into the physical state:

$$
\begin{equation*}
\mid \text { Hadron }\rangle=\text { V|I. R., currents }\rangle \text {. } \tag{4}
\end{equation*}
$$

The state |I.R., currents > corresponds to baryons being built from just three current quarks and mesons from quark-antiquark. Thus, for example, the complicated nucleon state is written as

$$
\begin{equation*}
|N>=V| \underline{56}, \quad\left\{(6,3)_{1 / 2}, 0\right\}>. \tag{5}
\end{equation*}
$$

All the complicated mixing of the real hadron states has been subsumed in the operator V .

In the following we will be interested in evaluating the hadronic matrix elements of charge or current operators, $\mathscr{O}^{\alpha}$ 。Using Eq。(4) we have

$$
\begin{equation*}
\left.<\text { Hadron }\left|\mathscr{O}^{\alpha}\right| \text { Hadron }\right\rangle=<\text { I.R.', currents } \mid V^{-1} \mathscr{O}^{\alpha} \text { VII. R. }, \text { currents }> \tag{6}
\end{equation*}
$$

The complexity of hadronic states under the algebra of currents has been transferred to the effective operator $\mathrm{V}^{-1} \mathscr{O}^{\alpha} \mathrm{V}$ which may be studied as an independent object. Moreover, if the operator $\mathrm{V}^{-1} \mathscr{O}^{\alpha} \mathrm{V}$ has definite and simple transformation properties under the algebra of currents, the way is open to systematically evaluate the matrix elements of $\mathscr{O}^{\alpha}$ between any two hadronic states.

The operator $V$ can be viewed in another way. It is easy to see that if we define a new set of generators

$$
\begin{equation*}
W^{i}=V F^{i} V^{-1} \tag{7}
\end{equation*}
$$

then the $W^{i}$ also form an $\operatorname{SU}(6)_{W}$ algebra. Furthermore, from the definition of $V$ in Eq. (4), hadron states transform under the $W^{i}$ as those irreducible representations which correspond to the naive constituent quark model of hadrons. We therefore call the quark states of this new $\mathrm{SU}(6)_{\mathrm{W}}$ constituent quarks, and identify this new algebra with that of the $\mathrm{SU}(6)_{\mathrm{W}}$ of strong interactions. ${ }^{12}$

Equation (4) can therefore be rewritten as

$$
\begin{equation*}
\text { - |Hadron } \left.\left.\rangle=\mid I_{.} \text {R. }_{\circ}, \text { constituents }\right\rangle=\text { V|I.R., currents }\right\rangle \text {, } \tag{8}
\end{equation*}
$$

while Eq. (6) becomes

$$
\begin{align*}
& \left.<\text { Hadron' }\left|\mathscr{O}^{\alpha}\right| \text { Hadron }\right\rangle \\
& \left.\quad=\langle\text { I.R.', constituents }| \mathscr{O}^{\alpha} \mid \text { I.R., constituents }\right\rangle \\
& \left.\quad=\langle\text { I.R.' , currents }| V^{-1} \mathscr{O}^{\alpha} \text { V|I.R., currents }\right\rangle . \tag{9}
\end{align*}
$$

From this standpoint the operator $V$ just takes one from one set of basis states to another, or alternately, from one set of generators to another.

In the free quark model, the $\operatorname{SU}(6)_{W}$ of strong interactions would be identical with the $S U(6)_{W}$ of currents if the quarks were restricted to have momentum purely in the $z$ direction $\left(p_{\perp}=0\right)$. This is intuitive if we keep in mind that the $\mathrm{SU}(6)_{\mathrm{W}}$ of strong interactions was conceived of as a collinear . symmetry. As we will see shortly, it is not symmetry respected in strong interaction transitions its conservation is badly violated in both pion and photon decays. In the present paper we are interested in current induced transitions between hadrons at $\mathrm{q}^{2}=0$ 。 For the axial-vector current, which is not conserved, the axial-vector charge induces non-trivial transitions and one wants to know the algebraic properties of the transformed charge, $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$. For the vector current, however, the corresponding charges $Q^{\alpha}$ generate $\operatorname{SU}(3)$, which is taken as exact, so that $V$ is an $\operatorname{SU}(3)$ singlet and

$$
\begin{equation*}
\mathrm{V}^{-1} \mathrm{Q}^{\alpha} \mathrm{V}=\mathrm{Q}^{\alpha} \tag{10}
\end{equation*}
$$

The first non-trivial operator involving the vector current is

$$
\begin{equation*}
D_{ \pm}^{\alpha}=i \int d^{3} x\left[\frac{\mp(x \pm i y)}{\sqrt{2}}\right] v_{0}^{\alpha}(\vec{x}, t) \tag{11}
\end{equation*}
$$

Matrix elements of $D_{ \pm}^{\alpha}$ between states at infinite momentum are proportional to vector current transition amplitudes where the $q^{2}=0$ current carries $J_{z}=\overrightarrow{ \pm} 1$, and we will then want to know the algebraic properties of $V^{-1} D_{ \pm}^{\alpha} V$. Taken between states at infinite momentum, commutators of $Q_{5}^{\alpha}$ lead to AdlerWeisberger sum rules, ${ }^{7}$ while commutators of $\mathrm{D}_{ \pm}^{\alpha}$ lead to Cabibbo-Radicati sum rules. ${ }^{13}$

The algebraic properties of the untransformed operators are that

$$
\begin{align*}
& Q_{5}^{\alpha} \text { transforms as }\left\{(8,1)_{0}-(1,8)_{0}, 0\right\}  \tag{12}\\
& \mathrm{D}_{ \pm}^{\alpha} \text { transforms as }\left\{(8,1)_{0}+(1,8)_{0}, \pm 1\right\} \tag{13}
\end{align*}
$$

For guidance on what might be the algebraic properties of $V^{-1} Q_{5}^{\alpha} V$ and $V^{-1} D_{ \pm}^{\alpha} V$, we turn to the free quark model. There Melosh ${ }^{1}$ has been able to construct an explicit form of the operator $V$. The transformation $V$ bears a strong similarity to the Foldy-Wouthuysen transformation, only restricted to transverse directions. In a free quark model, both $V^{-1} Q_{5}^{\alpha} V$ and $V^{-1} D_{ \pm}^{\alpha} V$ must connect only single quark states to single quark states; they thus have the general form:

$$
\begin{equation*}
\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V} \quad \text { or } \quad \mathrm{V}^{-1} \mathrm{D}_{ \pm}^{\alpha} \mathrm{V}=\int \mathrm{d}^{3} \mathrm{xq}^{+}(\mathrm{x}) \mathscr{\mathscr { H }}\left(\partial_{\perp}, \gamma_{\mathrm{i}}\right) \mathrm{q}(\mathrm{x}) \tag{14}
\end{equation*}
$$

where $\mathscr{F}$ is some function of the transverse derivatives $\left(\partial_{\perp}\right)$ and the gamma matrices $\left(\gamma_{i}\right)$ 。An explicit form of $\mathscr{F}$ was originally determined by Melosh, ${ }^{1}$ while Eichten et $\underline{\text { al }}^{14}$ argued that a large class of such functions exist. More recently, Melosh ${ }^{1}$ has restricted this class by imposing angular momentum transformation properties on the "rotated" currents. Without having a detailed dynamical theory we are unable to make use of an explicit form, even if it were given to us. What is important here is that the operator is a "single quark"
operator; i.e., it depends only on the coordinates of a single quark and it does not create connected $q \bar{q}$ pairs.

It is this property that we abstract from the free quark model and assume to hold in Nature. In general, we assume that: The operators $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$ and $\mathrm{V}^{-1} \mathrm{D}_{ \pm}^{\alpha} V$ have the transformation properties of the most general linear combination of single quark operators consistent with $\operatorname{SU}(3)$ and Lorentz invariance.

This is verified in the explicit free quark model calculations. The operator $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$, with $J_{\mathrm{z}}=0$, contains two terms which transform under $\operatorname{SU}(3) \times \operatorname{SU}(3)$ as $\left\{(8,1)_{0}-(1,8)_{0}, 0\right\}$ and $\left\{(3, \overline{3})_{1},-1\right\}-\left\{(\overline{3}, 3)_{-1}, 1\right\}$ and behave as components of 35 's of the full $\mathrm{SU}(6)_{\mathrm{W}}$ of currents. To apply this to observed hadron transitions in the case of $Q_{5}^{\alpha}$, as few axial-vector weak decays are measured, one needs to relate matrix elements of $Q_{5}^{\alpha}$ between states at infinite momentum to matrix elements of the pion field via the Partially Conserved Axial-Vector Current Hypothesis ${ }^{15}$ (PCAC) hypothesis. One then has a theory of the algebraic structure of pion amplitudes. ${ }^{16}$

As matrix elements of $D_{ \pm}^{3}+(1 / \sqrt{3}) D_{ \pm}^{8}$ are directly proportional to photon amplitudes, no additional assumption is necessary. Furthermore, matrix elements of $D_{+}^{\alpha}$ are equal, up to a sign, to those of $D_{-}^{\alpha}$ via parity conservation. We need then only consider the properties of $\mathrm{D}_{+}^{\alpha}$. Algebraically, the operator $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$, with $\mathrm{J}_{\mathrm{z}}=1$, is slightly more complicated than $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$. In general, as pointed out by Hey and Weyers, ${ }^{17}$ there are four possible terms: $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\}$, $\left\{(3, \overline{3})_{1}, 0\right\},\left\{(\overline{3}, 3)_{-1}, 2\right\}$, and $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$. It appears that all four occur in the operator $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ in the free quark model. ${ }^{1,14}$ However, the last term, which corresponds to $q \bar{q}$ in a net quark $\operatorname{spin} S=0$, unnatural spin-parity state, has no analogue with any natural spin-parity (in particular, vector meson) state of the quark model. Moreover, under a generalized parity transformation,
$P e^{-i \pi J_{y}}$, which takes $\left\{(A, B)_{S_{z}}, L_{z}\right\} \rightarrow\left\{(B, A)_{-S_{z}},-L_{z}\right\}$, the first three terms do not change sign while the last one does. For the longitudinal ( $\left.J_{z}=0\right)$ component of the current this would eliminate the possibility of such a term. Therefore the $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$ term in $D_{+}^{\alpha}$ has no correspondence with any natural spin-parity meson state and can not occur in the longitudinal component of the vector current. In the past we have therefore neglected such a term。 ${ }^{2,3,5}$ While we will carry all four terms in the remainder of this paper, we will at various times indicate experimental limits on the size of the $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$ term's contribution to various transitions and indicate what situation ensues if it is totally absent.

For photon decays, we have directly that in the narrow resonance approximation,
$\Gamma\left(\right.$ Hadron $^{\prime} \rightarrow$ Hadron $\left.+\gamma\right)$

$$
\begin{equation*}
\left.=\frac{\mathrm{e}^{2}}{\pi} \frac{\mathrm{p}_{\gamma}^{3}}{2 J^{\prime}+1}<\frac{-}{\lambda} \right\rvert\,<\text { Hadron', } \lambda\left|\mathrm{D}_{+}^{3}+\left(\frac{1}{\sqrt{3}}\right) \mathrm{D}_{+}^{8}\right| \text { Hadron, } \lambda-1>\left.\right|^{2} \tag{15}
\end{equation*}
$$

where $e$ is the proton charge, $p_{\gamma}$ the photon momentum, and the sum extends over all possible helicities $\lambda$. Matrix elements of $D_{\text {_ }}$ have been eliminated from Eq. (15) by relating them to those of $D_{+}$via parity. Note that although the definition of $D_{+}^{\alpha}$ in Eq. (11) involves only a first moment of the current, between states at infinite momentum all multipole amplitudes consistent with the spin and parity of the states enter matrix elements of $D_{+}^{\alpha}$. Equation (15) may also be obtained from consideration of the narrow resonance approximation to the "Hadron" " contribution to the Cabibbo-Radicati sum rule ${ }^{13}$ on "Hadron" states. We have no arbitrary phase space factors.

For the present we shall use the narrow resonance approximation expression, Eq. (15), for photon decay widths in order to make a comparison of the theory with experiment. For broad resonances in the initial and/or final state, or for decays of resonances where the physically available phase space is small, such an approximation introduces non-negligible errors. However, we view the present comparison as being sufficiently accurate as a first test of the theory, particularly in view of the experimental errors on values for photon (as well as pion) decay widths. When the situation eventually warrants it, the values of $\mid<$ Hadron' $\left|Q_{5}^{\alpha}\right|$ Hadron $>1^{2}$ and $\mid<$ Hadron' $\left|D_{+}^{\alpha}\right|$ Hadron $>\left.\right|^{2}$ should be determined irrespective of any approximation in terms of contributions to Adler-Weisberger and Cabbibo-Radicati sum rules respectively.

Thus, in spite of the enormous complication of $V$ itself, we abstract simple algebraic properties of $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$ and $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ from the free quark model and postulate them to hold in the real world. Namely, we assume that in Nature $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$ transforms as $\left\{(8,1)_{0}-(1,8)_{0}, 0\right\}$ and $\left\{(3, \overline{3})_{1},-1\right\}-\left\{(\overline{3}, 3)_{-1}, 1\right\}$ while $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ transforms as $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\},\left\{(3, \overline{3})_{1}, 0\right\},\left\{(\overline{3}, 3)_{-1}, 2\right\}$, and $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$, all components of 35 's of the full $\operatorname{SU}(6)_{W}$ of currents.

We are now almost in a position to apply the theory to actual decays. Recalling that, for example,

$$
\begin{align*}
&\left.<\text { I. R. })^{\prime}, \text { constituents }\left|D_{+}^{\alpha}\right| \text { I.R., constituents }\right\rangle \\
&\left.=\langle\text { I.R.', currents }| V^{-1} D_{+}^{\alpha} V \mid \text { I.R., currents }\right\rangle, \tag{16}
\end{align*}
$$

we see that with the assumed algebraic properties of $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ (as abstracted from the free quark model), we know the transformation properties under the $\mathrm{SU}(6)_{\mathrm{W}}$ of currents of all quantities in a given matrix element of $\mathrm{D}_{+}^{\alpha}$ between quark model states. To make contact with experiment we make one physical
assumption. Namely, we assume that we can identify the observed (non-exotic) hadrons with constituent quark states. In other words, we assume that there is a portion of the physical Hilbert space which is well approximated by the single particle states of the constituent quark model. For baryons, composed of qqq, we have candidates ${ }^{18}$ which fit very well into the $\operatorname{SU}(6)_{W} \times 0(3)$ representations $\underline{56} \mathrm{~L}=0, \underline{70} \mathrm{~L}=1$, and $\underline{56} \mathrm{~L}=2$. For mesons we have correspondingly the $\mathrm{q} \bar{q}$ states $35 \mathrm{~L}=0, \underline{1} \mathrm{~L}=0, \underline{35} \mathrm{~L}=1$, etc. As we assume that states with different values of the quark spin as well as $L_{z}$ and $S_{z}$ are related as in the constituent quark model, i.e., by the $\operatorname{SU}(6)_{W}$ of strong interactions, we relate different helicity states of a given hadron to each other.

With this physical assumption, we know the algebraic properties (under the algebra of currents) of all terms of a transformed matrix element of the current operators taken between physically observed states. Therefore we may use the Wigner-Eckart theorem and tables of Clebsch-Gordan coefficients to carry out the calculation from this point onward. Note that $\underline{S U(6)} \mathrm{W}$ invariance of the transition operator under either the algebra of currents or that of strong interactions is not assumed - only the transformation properties of the various terms are needed in the calculation.

More explicitly, for a given matrix element of $D_{+}^{\alpha}$ we write the initial and final hadron state with $J_{z}=\lambda-1$ and $\lambda$, respectively, in terms of states with definite quark $L_{Z}$ and $S_{z}$. This involves coupling internal $L$ and $S$ to form total $J$ for each hadron. After transforming to an $\operatorname{SU}(6)_{W}$ of currents basis using $V$, the matrix element of any particular term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ can then be written, using the Wigner-Eckart theorem applied to representations of the $\mathrm{SU}(6)_{\mathrm{W}}$ of currents, as a reduced matrix element times the product of quark angular momentum, ${ }^{\operatorname{SU}(6)_{W}}$, $\operatorname{SU}(3)$, and W -spin Clebsch-Gordan coefficients. ${ }^{19,20}$ For example,
suppose we were calculating the matrix element of the $\left\{(3, \overline{3})_{1}, 0\right\}$ piece of $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ between initial and final states with helicity $\lambda-1$ and $\lambda$, total angular momentum $J$ and $J^{\prime}$, internal quark orbital angular momentum $L$ and $L^{\prime}$, quark spin $S$ and $S^{\prime}, S U(6)_{W}$ representation $R$ and $R^{\prime}$, and $S U(3)$ representation $A$ and A' respectively. Then we have that
$<R^{\prime}, A^{\prime}, L^{\prime}, S^{\prime}, J^{\prime}, \lambda$, currents $\left|\left\{(3, \overline{3})_{1}, 0\right\}\right| R, A, L, S, J, \lambda-1$, currents $>$

$$
=\sum_{S_{z}, S_{7}^{\prime}}\left(L^{\prime} S_{z} S_{z} \mid J \lambda-1\right)\left(L^{\prime} S^{\prime} L_{Z}^{\prime} S_{Z}^{\prime} \mid J^{\prime} \lambda\right)\left\langle R^{\prime}\right| \underline{35}|R\rangle
$$

$S_{z}, S_{z}^{\prime} \quad$ quark angular momentum $\quad S U(6)_{W}$ Clebsch$L_{Z}, L_{Z}^{\prime} \quad$ Clebsch-Gordan coefficients Gordan coefficient.

$$
\left(A^{\prime}|\underline{8}| A\right) \quad\left(1 W 1 W_{z} \mid W^{\prime} W_{z}^{\prime}\right) \quad<R^{\prime}, L^{\prime}, L_{Z}^{\prime}\left\|\left\{(3, \overline{3})_{1}, 0\right\}\right\| R, L, L_{z}>
$$

SU(3) Clebsch- W-spin Clebsch-
Gordan coefficient Gordan coefficient Reduced matrix element

The W-spin Clebsch-Gordan coefficient follows since the $(3, \overline{3})$ operator has $W=1$ and $W_{z}=1$. For any state, $W_{z}=S_{z}$. For baryons, $\vec{W}=\vec{S}$, while for mesons we have the conventional correspondence ( $W$ - S flip), ${ }^{12}$

$$
\begin{align*}
& 1 \mathrm{~W}=1, \mathrm{~W}_{\mathrm{z}}=1>=1 \mathrm{~S}=1, \mathrm{~S}_{\mathrm{z}}=1> \\
& 1 \mathrm{~W}=1, \mathrm{~W}_{\mathrm{z}}=0>=-\mid \mathrm{S}=0, \mathrm{~S}_{\mathrm{z}}=0> \\
& 1 \mathrm{~W}=1, \mathrm{~W}_{\mathrm{z}}=-1>=-\mid \mathrm{S}=1, \mathrm{~S}_{\mathrm{z}}=-1> \\
& 1 \mathrm{~W}=0, \mathrm{~W}_{\mathrm{z}}=0>=-\mid \mathrm{S}=1, \mathrm{~S}_{\mathrm{z}}=0> \tag{18}
\end{align*}
$$

The signs which result from using Eq. (18) to convert states from quark spin to W -spin are understood to be included in Eq. (17) in the $S U(6)_{W}$ ClebschGordan coefficient.

The reduction of the other terms in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ proceeds just as above, and we need only recall that $(8,1)_{0}+(1,8)_{0} ;(8,1)_{0}-(1,8)_{0}$; and $(\overline{3}, 3)_{-1}$ transform as $\mathrm{W}=\mathrm{W}_{\mathrm{z}}=0 ; \mathrm{W}=1, \mathrm{~W}_{\mathrm{z}}=0$; and $\mathrm{W}=1, \mathrm{~W}_{\mathrm{z}}=-1$ objects respectively. Pion decays (matrix elements of $Q_{5}^{\alpha}$ ) are handled in an analogous manner, except, of course, the initial and final states have $J_{z}=\dot{\lambda}$. Note that since total $J_{z}$ is conserved for either Hadron' $\rightarrow$ Hadron $+\pi$ or Hadron' $\rightarrow$ Hadron $+\gamma$ decays, and since the net value of $W_{z}=S_{z}$ must also be the same by the $W$-spin ClebschGordan coefficient in Eq. (17) and its analogues, it follows that $L_{z}=J_{z}-S_{z}$ must also be additively conserved between the initial and final state (including the pion or photon operator).

The general structure of the results is now apparent. A matrix element of $D_{+}^{\alpha}\left(Q_{5}^{\alpha}\right)$ between hadron states will be equal to the sum of four (two) terms, each of which is a product of Clebsch-Gordan coefficients and a reduced matrix element which depends on the $\operatorname{SU}(6)_{W}$ multiplet (and $L_{z}$ values) of the external state components and the particular term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}\left(\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}\right)$ involved.

If $L$ is zero, as is the case in essentially all cases of physical interest at the present time, then of course $L_{z}=0$ and the $L_{z}^{\prime}$ dependence of the $\operatorname{SU}(6){ }_{W}$ reduced matrix element becomes trivial due to conservation of $L_{z}$. In such a case ( $L=0$ ), all photon decays from one $\mathrm{SU}(6)_{W}$ multiplet to another are related to the same four reduced matrix elements (dropping the trivial $L_{z}$ labels):
and

$$
\begin{aligned}
& <R^{\prime}, L^{\prime}\left\|(8,1)_{0}+(1,8)_{0}\right\| R, 0> \\
& <R^{\prime}, L^{\prime}\left\|(3, \overline{3})_{1}\right\| R, 0> \\
& <R^{\prime}, L^{\prime}\left\|(\overline{3}, 3)_{-1}\right\| R, 0> \\
& <R^{\prime}, L^{\prime}\left\|(8,1)_{0}-(1,8)_{0}\right\| R, 0>
\end{aligned}
$$

some of which may be zero or have zero coefficients due to selection rules. All pion decays (matrix elements of $Q_{5}^{\alpha}$ ) similarly depend on two reduced matrix elements

$$
\begin{aligned}
& <R^{\prime}, L^{\prime}\left\|(8,1)_{0}-(1,8)_{0}\right\| R, 0> \\
& <R^{\prime}, L^{\prime}\left\|(3, \overline{3})_{1}-(\overline{3}, 3)_{-1}\right\| R, 0>
\end{aligned}
$$

for given $\operatorname{SU}(6)_{W}$ multiplets $R^{\prime}, L^{\prime}$ and $R, L=0$.
This algebraic structure of photon matrix elements already leads to interesting and powerful selection rules. Consider the $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\}$ term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$, which has W spin zero. The W -spin Clebsch-Gordan coefficient in the analogue of Eq. (17) implies,

$$
\begin{equation*}
\overrightarrow{\mathrm{W}}^{\prime}=\overrightarrow{\mathrm{W}} \tag{19}
\end{equation*}
$$

which is the same as

$$
\begin{equation*}
\overrightarrow{\mathrm{S}}^{\prime}=\overrightarrow{\mathrm{S}} . \tag{20}
\end{equation*}
$$

Now, for the Hadron' and Hadron states we have

$$
\begin{equation*}
\overrightarrow{\mathrm{J}^{\prime}}=\overrightarrow{\mathrm{L}^{\prime}}+\overrightarrow{\mathrm{S}^{\prime}} \tag{21}
\end{equation*}
$$

and

$$
\begin{equation*}
\vec{J}=\overrightarrow{\mathrm{L}}+\overrightarrow{\mathrm{S}}, \tag{22}
\end{equation*}
$$

while angular momentum conservation for the total decay demands

$$
\begin{equation*}
\overrightarrow{\mathrm{J}}^{\prime}=\overrightarrow{\mathrm{J}}+\overrightarrow{\mathrm{j}}_{\gamma}, \tag{23}
\end{equation*}
$$

where $\mathrm{j}_{\gamma}$ is the net angular momentum carried by the photon and determines the multipole character of the decay.

Combining Eqs. (20) - (23) results in

$$
\begin{equation*}
\left|L-L^{\prime}\right| \leq j_{\gamma} \leq\left|L+L^{\prime}\right| \tag{24}
\end{equation*}
$$

and in the case $L=0$,

$$
\begin{equation*}
\mathrm{j}_{\gamma}=\mathrm{L}^{\prime} \tag{25}
\end{equation*}
$$

Thus decays through the $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\}$ term in $V^{-1} D_{+}^{\alpha} V$ to $L=0$ baryons or mesons always have $\mathrm{j}_{\gamma}=\mathrm{L}^{\prime}$ of the decaying hadron. As the parity change is $(-1)^{L^{\prime}-L}=(-1)^{L^{\prime}}=(-1)^{j_{\gamma}}$, this always corresponds to an electric $2 L^{\prime}$-pole transition in the usual multipole notation.

For the $\left\{(3, \overline{3})_{1}, 0\right\},\left\{(\overline{3}, 3)_{-1},+2\right\}$, and $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$ terms in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$, all of which have W -spin one, Eq. (20) is modified to ${ }^{21}$

$$
\begin{equation*}
\overrightarrow{\mathrm{S}^{\prime}}=\overrightarrow{\mathrm{S}}+\overrightarrow{1} \tag{26}
\end{equation*}
$$

and as a result one finds in place of Eq. (24) that

$$
\begin{equation*}
\left|\left|L-L^{\prime}\right|-1\right| \leq j_{\gamma} \leq\left|\left|L+L^{\prime}\right|+1\right| . \tag{27}
\end{equation*}
$$

For $L=0$ this simplifies to

$$
\begin{equation*}
\left|L^{\prime}-1\right| \leq j_{\gamma} \leq\left|L^{\prime}+1\right|, \tag{28}
\end{equation*}
$$

so that

$$
\begin{equation*}
j_{\gamma}=L^{\prime}-1, L^{\prime}, L^{\prime}+1 \tag{29}
\end{equation*}
$$

As the parity change is again $(-1)^{L^{\prime}}$, these correspond to magnetic $2\left(L^{\prime}-1\right)$-pole, electric $2 L^{\prime}$-pole, and magnetic $2\left(L^{\prime}+1\right)$-pole transitions, respectively.

The actual correspondence between reduced matrix elements and a set of multipole amplitudes can also be proven using Racah coefficients to rewrite Eq. (17) and its analogues. For example, baryon transitions from $R, L=0$ to
$R^{\prime}, L^{\prime}$ are describable in terms of multipole amplitudes

$$
\begin{equation*}
M\left(j_{\gamma}=L^{\prime}\right)=\left\langle R^{\prime}, L^{\prime}\left\|(8,1)_{0}+(1,8)_{0}\right\| R, L=0\right\rangle \tag{30a}
\end{equation*}
$$

and

$$
\begin{align*}
M\left(j_{\gamma}=L^{\prime}-1, L^{\prime}, L^{\prime}+1\right) & \left.=\left(1 L^{\prime} 10 \mid j_{\gamma} 1\right)<R^{\prime}, L^{\prime}\left\|(3, \overline{3})_{1}\right\| R, L=0\right\rangle \\
& +\left(1 L^{\prime} 01 \mid j_{\gamma} 1\right)<R^{\prime}, L^{\prime}\left\|(8,1)_{0}-(1,8)_{0}\right\| R, L=0> \\
& \left.+\left(1 L^{\prime}-12 \mid j_{\gamma} 1\right)<R^{\prime}, L^{\prime}\left\|(\overline{3}, 3)_{-1}\right\| R, L=0\right\rangle \tag{30b}
\end{align*}
$$

Note, of course, that one only has $j_{\gamma} \geq 1$. Thus for $L^{\prime}=0 \rightarrow L=0$, only $j_{\gamma}=1$ is allowed. This is just the old result ${ }^{4}$ that the nucleon to $3-3$ resonance transition is magnetic dipole in character in the case of baryons.

For pion decays a parallel analysis ${ }^{2,3}$ leads immediately to the rule

$$
\begin{equation*}
\dot{\mid} L-L^{\prime}\left|-1 \dot{1} \leq \ell \leq\left|\left|L+L^{\prime}\right|+1\right|\right. \text {, } \tag{31}
\end{equation*}
$$

where $\ell$ is the angular momentum carried by the pion. For $L=0$, this reduces to

$$
\begin{equation*}
\left|L^{\prime}-1\right| \leq \ell \leq\left|L^{\prime}+1\right|, \tag{32}
\end{equation*}
$$

and parity conservation forces the non-trivial result that

$$
\begin{equation*}
\ell=L^{\prime}-1 \quad \text { or } \quad L^{\prime}+1 \tag{33}
\end{equation*}
$$

Note that for values of $L^{\prime} \geq 3$, not only does the theory forbid values of $j_{\gamma}$ or $\ell$ larger than $L^{\prime}+1$, but it also non-trivially forbids ${ }^{22}$ values of $\mathrm{j}_{\gamma}$ or $\ell$ less than $L^{\prime}-1$ which are otherwise kinematically allowed, and even favored by angular momentum barrier arguments. The transition of a $J^{P}=3 / 2^{-}$baryon resonance in a $\underline{70} L^{\prime}=3$ multiplet into a nucleon plus a photon with $\mathrm{j}_{\mu}=1$ is forbidden, for example, even though this is the lowest allowed multipole on spinparity grounds.

The algebraic structure of the theory of photon transitions presented above is closely related to various quark model calculations, both non-relativistic ${ }^{23}$ and relativistic, ${ }^{24}$ done in the past. They may be put into one to one correspondence if the $(8,1)_{0}+(1,8)_{0}$ term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ is identified with the photon interacting with the quark convection current, and the $(3, \overline{3})_{1}$ term identified with the photon interacting with the quark magnetic moments. The $(\overline{3}, 3)-1$ and $(8,1)_{0}-(1,8)_{0}$ terms in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ do not appear in these quark models. ${ }^{23,24}$ Therefore one can make a complete algebraic correspondence with the identification of certain combinations of parameters there with the reduced matrix elements discussed here. However, the assumption of a "potential" and the resulting wave functions for the bound states in the quark model calculations yield definite predictions for the reduced matrix elements themselves as they depend on masses and other parameters of the model. This is something we do not obtain, since we consider only the algebraic structure.

A similar correspondence occurs for pion decays. The results of the nonrelativistic quark model ${ }^{25}$ (no recoil) correspond to keeping only the $(8,1)_{0}-(1,8)_{0}$ term in $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$ while the relativistic quark model ${ }^{24}$ yiclds amplitudes corresponding to the presence of both the $(8,1)_{0}-(1,8)_{0}$ and $(3, \overline{3})_{1}-(\overline{3}, 3)_{-1}$ reduced matrix elements discussed here.

Closely related to the quark model results are those following from various versions of $\mathrm{SU}(6)_{\mathrm{W}}$ (of strong interactions) invariance. ${ }^{12}$ The results of assuming $\mathrm{SU}(6)_{\mathrm{W}}$ conservation for pion transitions are reproduced in the present theory by retaining only the $\left\{(8,1)_{0}-(1,8)_{0}, 0\right\}$ term in $V^{-1} Q_{5}^{\alpha} V$ and using PCAC. The assumption of $\operatorname{SU}(6)_{\mathrm{W}}$ conservation plus vector dominance is equivalent to keeping only the $\left\{(3, \overline{3})_{1}, 0\right\}$ term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$.

As we will soon see, this is totally contradicted by the data. As a result, various broken $\mathrm{SU}(6)_{W}$ schemes were developed. ${ }^{26}$ Some of these are very similar to the present theory in algebraic structure, particularly for decays to $L=0$ hadrons.

The relation of such schemes for pion decays, and in particular $\ell$-broken $S U(6)_{W}$, to the present theory is discussed in detail in Ref. 27. For vector meson decays, and via vector dominance for photon decays, one such scheme ${ }^{28}$ corresponds in algebraic structure to the one presented here if the reduced matrix element of the $\left\{(\overline{3}, 3)_{-1}, 2\right\}$ term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ vanishes and those of the $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\}$ and $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$ terms are equal.

## II. PHOTON TRANSITIONS OF MESONS

Now that the basic properties of the theory and the manner of its application to actual hadrons have been spelled out, we begin the discussion of detailed predictions with radiative meson decays. We limit our listing of amplitudes to those corresponding to non-strange mesons; the extension to transitions involving strange mesons is easily accomplished using $\mathrm{SU}(3)$.

Let us begin with the photon transitions from $L^{\prime}=0$ to $L=0$ mesons, i.e., among the members of the $\operatorname{SU}(6)_{W} 35$ and 1 , whose non-strange members are the $\rho, \omega, \phi, \pi, \eta$, and (presumably) $X^{0} \operatorname{As~}^{0} L_{\mathrm{Z}}^{\prime}=\mathrm{L}_{\mathrm{Z}}=0$ for the external states follows from $L=L^{\prime}=0$, only the term with $L_{z}=0$ and transforming as $\left\{(3, \overline{3})_{1}, 0\right\}$ in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ can contribute. The selection rule in Eq 。(28) immediately gives the result that $j_{\gamma}=1$ only. This is already non-trivial, as $j_{\gamma}=2$ transitions are possible from $\rho^{ \pm}$to $\rho^{ \pm}$in general, and the theory then predicts zero electric quadrupole moment for the $\rho$ meson.

Since W-spin zero octets and singlets belong to the $\underline{35}$ and $\underline{1}$ representations of $S U(6)_{W}$, respectively, decays involving meson states which are mixtures of $\dot{W}=0 \overrightarrow{\mathrm{~S}} \mathrm{U}(3)$ octets and singlets may be used to fix the ratio of the $<\underline{1} \mathrm{~L}^{\prime}=0\left\|(3, \overline{3}){ }_{1}\right\| \underline{35} \mathrm{~L}=0>$ and $\left\langle\underline{35} \mathrm{~L}^{\prime}=0\|(3, \overline{3}) \underline{1}\| \underline{\mathrm{35}} \mathrm{L}=0>\right.$ 。 In particular, for this purpose we use Zweig's rule ${ }^{29}$ to forbid the decay $\phi \rightarrow \gamma \pi$, where the $\phi$ is assumed to be the usual ideal mixture of singlet and octet so as to be composed of purely strange quarks. All amplitudes are then multiples of a single magnetic dipole amplitude, or alternatively, are proportional to the single reduced matrix element,

$$
\left\langle\underline{35} \mathrm{~L}^{\prime}=0\left\|(3, \overline{3})_{1}\right\| \underline{35} \mathrm{~L}=0>.\right.
$$

One observed transition then fixes all the other decay rates. ${ }^{30}$ The results of the computation of transition matrix elements are given in Table I where the $\eta$ and $\mathrm{X}^{\mathrm{O}}$ are assumed to be $\mathrm{SU}(3)$ octet and singlet respectively while the $\omega$ and $\phi$ are ideal mixtures of octet and singlet:

$$
\begin{align*}
& \omega=\cos \theta \omega^{(1)}+\sin \theta \omega^{(8)} \\
& \phi=-\sin \theta \omega^{(1)}+\cos \theta \omega^{(8)} \tag{34}
\end{align*}
$$

where

$$
\sin \theta=+\sqrt{1 / 3} .
$$

Table II contains the corresponding predictions for all the $L^{\prime}=0 \rightarrow L=0$ radiative decay widths using $\Gamma(\omega \rightarrow \gamma \pi)=890 \mathrm{KeV}$ as input. ${ }^{31}$ The sparse experimental data 31,32 are also given. Note that the predictions in the first column are for unmixed pseudoscalar mesons. Taking a mixing angle ${ }^{33}$ $\theta_{\mathrm{p}}=-10.5^{\circ}$, as suggested by a quadratic mass formula, gives the second column. The predicted width for $\phi \rightarrow \gamma \eta$ is reduced to 170 KeV , agreeing with
experiment within errors。 ${ }^{34}$ The corresponding prediction in this case for $\Gamma\left(\mathrm{X}^{0} \rightarrow \gamma \rho\right)$ is 120 KeV . Assuming that $\mathrm{X}^{0} \rightarrow \gamma \pi^{+} \pi^{-}$is dominated by $\mathrm{X}^{0} \rightarrow \gamma \rho$, and taking the branching ratio ${ }^{31}$ for this mode to be $26 \%$, we find a total $\mathrm{X}^{\mathrm{O}}$ width of 460 KeV . This is also consistent with the $\mathrm{X}^{\circ}$ width obtained from the branching ratio ${ }^{31}$ for $\mathrm{X}^{\circ} \rightarrow \gamma \gamma$ plus $\mathrm{SU}(3)$ and the new value ${ }^{35}$ of $\Gamma(\eta \rightarrow \gamma \gamma)$ 。The overall situation for $L^{\prime}=0 \rightarrow L=0$ decays is thus quite satisfactory, although many pieces of information are absent in comparing theory and experiment.

When we go to $L^{\prime}=1$ to $\mathrm{L}=0$ decays, there is no experimental information available, although there are both many amplitudes and many predictions. Of the four terms generally present in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$, only $\left\{(\overline{3}, 3)_{-1}, 2\right\}$ can not contribute (since it changes $L_{z}$ by two units). The selection rules of Section II show that the $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\}$ term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ leads to purely electric dipole $\left(j_{\gamma}=1\right)$ transitions, and only $j_{\gamma}=1$ and 2 can arise from the $\left\{(3, \overline{3})_{1}, 0\right\}$ $\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$ terms. In fact it is possible to express linear combinations of their reduced matrix elements as electric dipole and magnetic quadrupole amplitudes, multiples of which occur in all decays from $L^{\prime}=1$ to $L=0$ mesons.

All possible radiative decay amplitudes for non-strange $L^{\prime}=1$ mesons ${ }^{36}$ to $\mathrm{L}=0$ mesons are given in Table III in terms of the reduced matrix elements

$$
\begin{aligned}
& \left\langle\underline{35} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{35} \mathrm{~L}=0>,\left\langle\underline{35} \mathrm{~L}^{\prime}=1\left\|(3, \overline{3})_{1}\right\| \underline{35} \mathrm{~L}=0>,\right.\right. \\
& \text { and }\left\langle\underline{35} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{35} \mathrm{~L}=0>\right.
\end{aligned}
$$

Matrix elements of $\operatorname{SU}(6)_{\mathrm{W}}$ singlet states are related to those in the $\underline{35}$ by using Zweig's rule, ${ }^{29}$ as was done above for $L^{\prime}=0$ to $L=0$ decays. The $\eta$ and H are assumed to be purely octet members, while the $\mathrm{f}, \mathrm{D}, \sigma$, and $\omega$ are all taken to be ideal mixtures of singlets and octets, so as to be composed of only non-strange quarks. Note that in the decay $2^{+} \rightarrow \gamma 1^{-}, e_{.} g_{\circ}, A_{2} \rightarrow \gamma \rho$, an
electric octupole amplitude could be present in principle, as well as electric dipole and magnetic quadrupole amplitudes. However, the selection rule limiting $j_{\gamma}$ to 1 or 2 eliminates the octupole amplitude and results in the linear relation

$$
\begin{equation*}
\mathrm{A}_{\lambda=2}\left(\mathrm{~A}_{2} \rightarrow \gamma \rho\right)=2 \sqrt{2} \mathrm{~A}_{\lambda=1}\left(\mathrm{~A}_{2} \rightarrow \gamma \rho\right)-\sqrt{6} \mathrm{~A}_{\lambda=0}\left(\mathrm{~A}_{2} \rightarrow \gamma \rho\right), \tag{35}
\end{equation*}
$$

among the three helicity amplitudes for $2^{+} \rightarrow \gamma 1^{-}$。Almost any experimental information on these decays would be helpful in sorting out the relative importance of the various (3) possible amplitudes, and in testing the theory.

## IV. PHOTON TRANSITIONS BETWEEN BARYONS

The electromagnetic transitions of baryons provide a second and very rich area of predictions for the theory. As before, we restrict our attention primarily to non-strange baryons decaying into $\mathrm{L}=0$ states, this being by far the main area for experimental comparison. In this section wंe will enumerate the possible decay amplitudes, deferring an experimental comparison to the next section.

The case of transitions from $56 \mathrm{~L}^{\prime}=0$ to $56 \mathrm{~L}=0$, i.e., within the $\mathrm{L}=0$ baryon multiplet, is particularly simple. As for mesons, only magnetic dipole transitions are allowed by the theory and all amplitudes are proportional to a single reduced matrix element, that of the term transforming as $\left\{(3, \overline{3})_{1}, 0\right\}$ in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$. The results are presented in Table IV for the three possible transitions $N \rightarrow N, N \rightarrow \Delta$ and $\Delta \rightarrow \Delta$. It can be explicitly checked that all the transitions are magnetic dipole in character, as demanded by the selection rule (Eq. (28)), including those for $\Delta \rightarrow \Delta$ where both electric quadrupole and magnetic octupole transitions are also possible in principle.

For decays from the next identified baryon multiplet, the $70 L^{\prime}=1$, to the ground state $56 \mathrm{~L}=0$ we have the three possible reduced matrix elements

$$
\begin{aligned}
& <\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0> \\
& <\underline{70} \mathrm{~L}^{\prime}=1\left\|(3, \overline{3})_{1}\right\| 56 \mathrm{~L}=0>
\end{aligned}
$$

and

$$
<\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>0
$$

The matrix elements of $D_{+}^{\alpha}$ for decays into both $\gamma \mathrm{N}$ and $\gamma \Delta$ are enumerated ${ }^{37}$ in Table V in terms of these reduced matrix elements.

By the selection rules of Section II, the $(8,1)_{0}+(1,8)_{0}$ term in $V^{-1} D_{+}^{\alpha} V$ acts as an electric dipole transition operator, while the two remaining terms act as a combination of electric dipole ( $\mathrm{j}_{\gamma}=1$ ) and magnetic quadrupole ( $\mathrm{j}_{\gamma}=2$ ). According to the discussion around Eq. (30) in Section II we can in fact write amplitudes,

$$
\begin{align*}
\mathrm{E}^{\prime}= & \left\langle\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56}, \mathrm{~L}=0\right\rangle \\
\mathrm{E} 1= & \left.\sqrt{1 / 2}<\underline{70} \mathrm{~L}^{\prime}=1\left\|(3, \overline{3})_{1}\right\| \underline{56}, \mathrm{~L}=0\right\rangle \\
& \left.-\sqrt{1 / 2}<\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56}, \mathrm{~L}=0\right\rangle \\
\mathrm{M} 2= & \left.\sqrt{1 / 2}<\underline{70} \mathrm{~L}^{\prime}=1\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0\right\rangle \\
& \left.+\sqrt{1 / 2}<\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}-(1,8)_{0}\right\| 56 \mathrm{~L}=0\right\rangle, \tag{36}
\end{align*}
$$

which are electric dipole and magnetic quadrupole amplitudes in terms of which all the helicity decay amplitudes given in Table V may be alternately expressed. Note that $\mathrm{N}^{*}\left(\mathrm{~J}^{\mathrm{P}}=5 / 2^{-}\right) \rightarrow \gamma \mathrm{N}$, for example, could in general go via $\mathrm{j}_{\gamma}=2$ or 3 , but only $\mathrm{j}_{\gamma}=2$ (magnetic quadrupole) is allowed by the theory. Similarly, $\mathrm{N}^{*}\left(5 / 2^{-}\right) \rightarrow \gamma \Delta$ could proceed with $\mathrm{j}_{\gamma}=1,2,3$ or 4 in general, but only $j_{\gamma}=1$ and 2 are allowed by the theory. Note also that the Moorhouse quark model
selection rule ${ }^{38}$ forbidding $\gamma \mathrm{p} \rightarrow \mathrm{N}^{*^{+}}$, where the $\mathrm{N}^{*}$ has quark spin $\mathrm{S}=3 / 2$, is reflected in Table V.

For $56 L^{\prime}=2$ decays to $56 \mathrm{~L}=0$ we have reached a high enough value of $L^{\prime}$ that all four terms in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ can contribute to the decay amplitudes. In this case the $(8,1)_{0}+(1,8)_{0}$ term is electric quadrupole $\left(j_{\gamma}=2\right)$ in character, while linear combinations of the other three terms act as $j_{\gamma}=1,2$, and 3 transitions:

$$
\begin{align*}
\mathrm{E} 2^{\prime}= & \left\langle\underline{56} \mathrm{~L}=2^{\prime}\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0\right\rangle \\
\mathrm{M} 1= & \sqrt{1 / 10}<\underline{56} \mathrm{~L}=2^{\prime}\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0> \\
& -\sqrt{3 / 10}<\underline{56} \mathrm{~L}=2^{\prime}\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0> \\
& +\sqrt{3 / 5}<\underline{56} \mathrm{~L}^{\prime}=2\left\|(\overline{3}, 3)_{-1}\right\| \underline{56} \mathrm{~L}=0> \\
\mathrm{E} 2= & \sqrt{1 / 2}<\underline{56} \mathrm{~L}=2^{\prime}\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0> \\
& -\sqrt{1 / 6}<\underline{56} \mathrm{~L}=2^{\prime}\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0> \\

\mathrm{M} 3= & \sqrt{6 / 15}<\underline{56} \mathrm{~L}=2^{\prime}\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0> \\
& +\sqrt{8 / 15}<\underline{56} \mathrm{~L}=2^{\prime}\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0> \\
& +\sqrt{1 / 15}<\underline{56} \mathrm{~L}^{\prime}=2\left\|(\overline{3}, 3)_{-1}\right\| \underline{56} \mathrm{~L}=0>0 \tag{37}
\end{align*}
$$

The various amplitudes for resonances in the $56 \mathrm{~L}^{\prime}=1$ to decay into $\gamma \mathrm{N}$ are listed ${ }^{37}$ in Table VI. The $\gamma \Delta$ amplitudes are straightforward to work out, ${ }^{39}$ but at present add little of interest. Again, the selection rules derived in Section II have clear and direct consequences: $\Delta\left(7 / 2^{+}\right) \rightarrow \gamma \mathrm{N}$, for example, which could go by $j_{\gamma}=3$ or 4 is restricted to be purely magnetic octupole $\left(j_{\gamma}=3\right)$.

Decays from higher $L^{\prime}$ multiplets are easily computable, but little in the way of experimental tests is available at present. For the $56 L^{\prime}=0, \underline{70} \mathrm{~L}^{\prime}=1$, and
$56 \mathrm{~L}^{\prime}=2$ photon transition amplitudes to $\underline{56} \mathrm{~L}=0$ which we have enumerated, however, photoproduction data permits many direct experimental comparisons. To the $\overrightarrow{\text { se }}$ we now turn.

## V. EXPERIMENTAL TESTS OF BARYON AMPLITUDES

The predictions for transitions within the $56 \mathrm{~L}=0$ multiplet are already testable using the magnetic moments of the neutron and proton, for a direct evaluation of $D_{+}^{\alpha}$ between nucleon states at infinite momentum gives

$$
\begin{equation*}
\left.\mu_{\mathrm{A}}=+\left(\frac{1}{\sqrt{2}}\right)<\mathrm{N}, \lambda=1 / 2\left|\mathrm{D}_{+}^{\alpha}\right| \mathrm{N}, \lambda=-1 / 2\right\rangle, \tag{38}
\end{equation*}
$$

where $\mu_{\mathrm{A}}$ is the anomalous magnetic moment of the nucleon. However, a careful calculation of $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ between one nucleon states at infinite momentum gives a result ${ }^{1}$ which has the transformation properties of the four terms discussed in Section II minus a term which is exactly the Dirac moment. Adding the Dirac to the anomalous moment, we see that the four terms in $V^{-1} D_{+}^{\alpha} V$ discussed before should be interpreted as being proportional to the total moment when taken between the same initial and final state. Thus, the matrix elements in Table IV are to be interpreted as predicting,

$$
\begin{equation*}
\mu_{\mathrm{T}}(\mathrm{n}) / \mu_{\mathrm{T}}(\mathrm{p})=-2 / 3, \tag{39}
\end{equation*}
$$

the $\operatorname{SU}(6)$ result, ${ }^{40}$ which is within $5 \%$ of the experimental value of $-1.91 / 2.73$ $=-0.70$.

For the transition from $\Delta$ to $N$ the ratio of $\sqrt{3}$ between the $\lambda=3 / 2$ and $\lambda=1 / 2$ matrix elements corresponds to a pure magnetic dipole transition, as we already know must occur from the discussion in the last section. All photoproduction analyses ${ }^{41}$ agree that the electric quadrupole amplitude is at most a few percent of the magnetic dipole amplitude for excitation of the 3-3 resonance.

The strength of this transition, $\mu^{*}$, is conventionally defined so that

$$
\begin{equation*}
\mu^{*}=\sqrt{2}\langle\Delta, \lambda=1 / 2| D_{+}^{\alpha}|N, \lambda=-1 / 2\rangle . \tag{40}
\end{equation*}
$$

The results in Table IV then translate to

$$
\begin{equation*}
\mu^{*} / \mu_{\mathrm{T}}(\mathrm{p})=+(2 / 3) \sqrt{2} . \tag{41}
\end{equation*}
$$

An older phenomenological analysis ${ }^{42}$ of the data for pion photoproduction gave a result for $\mu^{*} / \mu_{\mathrm{T}}(\mathrm{p})$ which is $1.28 \pm 0.03$ times the right hand side of Eq. (41) by finding the residue at the $\Delta$ pole in $\gamma \mathrm{N} \rightarrow \pi \mathrm{N}$. By considering the contribution ${ }^{43}$ of the $\Delta$ to the Cabibbo-Radicati sum rule we find a value of $\mu^{*} / \mu_{\mathrm{T}}$ (p) which is $0.9 \pm 0.1$ times the right hand side of Eq. (41), and in quite satisfactory agreement with the theory. While the sign of $\mu^{*} / \mu_{\mathrm{T}}(\mathrm{p})$ can not be measured, the product of the $\gamma \mathrm{N}$ and $\pi \mathrm{N}$ couplings of the nucleon can be compared with that of the 3-3 resonance in pion photoproduction. As the theory ${ }^{2,3}$ also predicts the relative sign of the $\pi \mathrm{N}$ couplings, it makes an unambiguous prediction of the sign of the resonance excitation amplitude relative to the nucleon Born terms. This sign is correctly given by the theory. 44

For the transition from $\Delta$ to $\Delta$, which is also purely magnetic in character, we should again interpret the results in Table IV as being for the total moment. The relation between matrix elements of $D_{+}$and the conventional anomalous magnetic moment of the $\Delta, \mu_{A}^{* *}$, is

$$
\begin{equation*}
\mu_{\mathrm{A}}^{* * i}=-\sqrt{3 / 2}<\Delta, \lambda=3 / 2\left|\mathrm{D}_{+}^{\alpha}\right| \Delta, \lambda=1 / 2>. \tag{42}
\end{equation*}
$$

From this we see that we have from Table IV,

$$
\begin{align*}
& \mu_{\mathrm{T}}^{* *}\left(\Delta^{++}\right) / \mu_{\mathrm{T}}(\mathrm{p})=2 \\
& \mu_{\mathrm{T}}^{* *}\left(\Delta^{+}\right) / \mu_{\mathrm{T}}(\mathrm{p})=1 \\
& \mu_{\mathrm{T}}^{* *}\left(\Delta^{\mathrm{o}}\right) / \mu_{\mathrm{T}}(\mathrm{p})=0 \\
& \mu_{\mathrm{T}}^{* *}\left(\Delta^{-}\right) / \mu_{\mathrm{T}}(\mathrm{p})=-1 \tag{43}
\end{align*}
$$

As with Eqs. (39) and (41), all these are standard $\operatorname{SU}(6)$ results, ${ }^{40}$ as is to be expected since the $\{(3, \overline{3}), 0\}$ term in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ has the same transformation properties as the magnetic moment operator used in $\operatorname{SU}(6)$.

The transitions from the $\underline{70} \mathrm{~L}^{\prime}=1$ to the ground state $\underline{56} \mathrm{~L}=0$ provide a much richer set of amplitudes for comparison of theory and experiment. Rather than carry out a statistical "best fit" to all the data, in Table VII we have fixed the possible reduced matrix elements allowed by the theory in terms of a some relatively well determined amplitudes for the process $\gamma \mathrm{N} \rightarrow \mathrm{D}_{13}(1520) \rightarrow \pi \mathrm{N}$.

The quantities in the table are the matrix elements of $D_{+}^{3}+(1 / \sqrt{3}) D_{+}^{8}$ taken between identified resonant states ${ }^{18}$ in the $\underline{70}$ with $J_{z}=\lambda$ and nucleon states with $J_{z}=\lambda-1$. The signs are those found in the specific processes $\gamma p \rightarrow \mathbb{N}^{*^{+}} \rightarrow \pi^{+} n$ and $\gamma \mathrm{n} \rightarrow \mathrm{N}^{*^{\circ}} \rightarrow \pi^{-} \mathrm{p}$. To make a theoretical prediction of these signs we need a theory of both the $\gamma \mathrm{NN}^{*}$ and $\pi \mathrm{NN}^{*}$ vertices. The $\gamma \mathrm{NN}^{*}$ couplings are taken from Table $V$ while for $\underline{70} \mathrm{~L}^{\prime}=1 \rightarrow \underline{56} \mathrm{~L}=0$ pion transitions we may express the reduced matrix elements of the two terms in $\mathrm{V}^{-1} \mathrm{Q}_{5}^{\alpha} \mathrm{V}$ as linear combinations of amplitudes $S$ and $D$, corresponding to $\ell-0$ and $2:{ }^{45}$

$$
\begin{align*}
& <\underline{70}, L^{\prime}=1\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56}, \mathrm{~L}=0>=\frac{1}{3}(\mathrm{~S}+2 \mathrm{D}) \\
& <\underline{70}, \mathrm{~L}^{\prime}=1\left\|(3, \overline{3})_{1}-(\overline{3}, 3)_{-1}\right\| \underline{56}, \mathrm{~L}=0>=\frac{1}{3}(\mathrm{~S}-\mathrm{D}) . \tag{44}
\end{align*}
$$

Then $\mathrm{S}=+\mathrm{D}$ if only the $(8,1)_{0}-(1,8)_{0}$ term in $\mathrm{V}^{-1} Q_{5}^{\alpha} \mathrm{V}$ is present, while $\mathrm{S}=-2 \mathrm{D}$ if only $(3, \overline{3})_{1}-(\overline{3}, 3)_{-1}$ is present. While an earlier phase shift solution ${ }^{46}$ to the $\pi N \rightarrow \vec{\pi} \Delta$ data disagreed with the signs predicted for pion transitions, a new solution agrees completely ${ }^{47}$ and shows that the signs of $S$ and $D$ are opposite, i.e., it appears the $(3, \overline{3})_{1}-(\overline{3}, 3)_{-1}$ reduced matrix element is dominant for $\underline{70} \mathrm{~L}^{\prime}=1 \rightarrow \underline{56} \mathrm{~L}=0$ pion decays. In constructing Table VII we have taken the $\pi$ NN* couplings from Table $V$ of Ref. 3 and have assumed that the signs of $S$ and $D$ are opposite in calculating the $\pi N_{N *}$ vertex sign. Mixing between the two $S_{11}$ or two $\mathrm{D}_{13}$ states in the 70 has been neglected in calculating the predicted amplitudes.

The "data" is taken from a very recent analysis ${ }^{48}$ of electromagnetic couplings of $\mathrm{N}^{*}$ resonances from single pion photoproduction data. In terms of amplitudes $A_{\lambda}$ for $\gamma N \rightarrow N^{*}$ of that analysis, ${ }^{48}$ matrix elements of $D_{+}^{3}+(1 \sqrt{3}) D_{+}^{8}$ are related by

$$
\begin{equation*}
\left\langle N^{*}, \lambda\right| D_{+}^{3}+(1 \sqrt{3}) D_{+}^{8}|N, \lambda-1\rangle=\left(\frac{M_{N}}{2 \pi \alpha M_{N}{ }^{*} P_{\gamma}}\right)^{1 / 2} A_{\lambda} \tag{45}
\end{equation*}
$$

where $\mathrm{p}_{\gamma}$ is the photon momentum in the $\mathrm{N}^{*}$ rest frame, and $\lambda$ can take the values $1 / 2$ and $3 / 2$. The results of Ref. 48 generally agree well with those of another recent ${ }^{49}$ analysis, although the "errors" on the amplitudes quoted in the latter are much larger. Judging from the differences between successive or independent analyses, we would opt for larger "errors" than those of Ref. 48, which are reproduced in Table VII.

As a first comparison, we set the reduced matrix element $<\underline{70} \mathrm{~L}^{\prime}=1 \|(8,1)_{0}$ $-(1,8)_{0} \| 56 \mathrm{~L}=0>$ equal to zero, so that we are left with only the two terms in $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ which are present in quark model calculations. ${ }^{23,24}$ The well-determined amplitude for $\gamma \mathrm{p} \rightarrow \mathrm{D}_{13}^{+}(1520)$ with $\lambda=3 / 2$ then determines
$<\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>$ directly and fixes an overall free sign。 The $\lambda=1 / 2$ transition to the same resonance then fixes $<\underline{70} \mathrm{~L}^{\prime}=1\|(3, \overline{3}) 1\| 56 \mathrm{~L}=0>$ 。 In fact, the smallness of the $\lambda=1 / 2$ amplitude means that

$$
\begin{align*}
<\underline{70} L^{\prime} & \left.=1 \|(8,1)_{0}+(1,8)\right)_{0} \| \underline{56} \mathrm{~L}=0> \\
& \simeq 2<\underline{70} \mathrm{~L}^{\prime}=1\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0> \tag{46}
\end{align*}
$$

The signs of the resulting amplitudes are exactly those discussed by us previously. ${ }^{5}$ All the well determined ones agree in sign with experiment (nine in addition to the input). However, the magnitudes of a number of the predicted amplitudes are not in such great agreement with experiment. The $\lambda=3 / 2 \mathrm{ampli}-$ tude for $\gamma \mathrm{n} \rightarrow \mathrm{D}_{13}^{0}(1520)$ is too large. Mixing, at least with the small mixing angles otherwise suggested, ${ }^{50}$ will not cure this, although it could well help improve the situation with regard to the poorly-known $\mathrm{D}_{13}(1700)$ amplitudes.

For the two $\mathrm{S}_{11}$ states, a fairly large mixing angle is known to be necessary from other considerations, ${ }^{50}$ and would give $S_{11}(1700)$ amplitudes which agree with experiment in sign. The predicted $\mathrm{S}_{11}(1535)$ amplitudes would still be much too large, however. The amplitudes predicted for the $S_{31}$ and $D_{33}$ also are all too large, and no mixing (within the 70) is possible in these cases. A fit to all the data would of course scale down the reduced matrix elements, making the agreement better for the magnitudes of the $\mathrm{S}_{31}, \mathrm{D}_{33}$, and $\mathrm{S}_{11}$ amplitudes, at some cost to those of the $\mathrm{D}_{13}(1520)$.

A second comparison of the theory with experiment is also found in Table VII where all three possible reduced matrix elements are allowed to be non-zero, and fixed by the transitions $\gamma \mathrm{p} \rightarrow \mathrm{D}_{13}^{+}(1520)$ with $\lambda=1 / 2$ and $3 / 2$, and $\gamma \mathrm{n} \rightarrow \mathrm{D}_{13}^{o}(1520)$ with $\lambda=3 / 2$. Again, all the well determined signs agree with experiment, although the predicted (and poorly determined experimentally) signs for the $\mathrm{D}_{13}(1700)$ and $S_{11(1700)}$ are opposite to those discussed above.

There is still trouble in this case with the magnitudes of various amplitudes. The $\lambda=1 / 2, \gamma \mathrm{n} \rightarrow \mathrm{D}_{13}^{\circ}$ amplitude is too small, as is the amplitude for $\gamma \mathrm{p} \rightarrow \mathrm{S}_{11}^{+}(1535)$. Mixing only hurts here, as the $\gamma \mathrm{p}$ transition to the other $\mathrm{S}_{11}$ is forbidden, resulting in an even smaller prediction for $\gamma \mathrm{p} \rightarrow \mathrm{S}_{11}^{+}(1535)$ and too small a result as well for $\gamma \mathrm{p} \rightarrow \mathrm{S}_{11}^{+}(1700)$. Although the $\mathrm{D}_{33}$ amplitude predictions now agree well with experiment, that for the $S_{31}$ is still much too large.

It is interesting to note that for this second fit we have

$$
\begin{align*}
<\underline{70} \mathrm{~L}^{\prime} & =1\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0> \\
& \simeq<\underline{70} \mathrm{~L}^{\prime}=1\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>, \\
<\underline{70} \mathrm{~L}^{\prime} & =1\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0>\simeq 0 . \tag{47}
\end{align*}
$$

Equality of the first two reduced matrix elements is exactly what is forced by vector dominance plus the scheme of Petersen and Rosner ${ }^{28}$ for vector meson decays. The reason why $<\underline{70} \mathrm{~L}=1\|(3, \overline{3})\|_{1} \underline{56} \mathrm{~L}=0>$ should be so small, which in the fit is forced by the smallness of the amplitude for $\gamma \mathrm{p} \rightarrow \mathrm{D}_{13}^{+}(1520)$ with $\lambda=1 / 2$, is possibly an interesting theoretical problem.

At the present time, given the uncertainties we feel exist in the electromagnetic couplings of the $\mathrm{N}^{* /} \mathrm{s}$, either set of predictions should be regarded as in fair agreement with experiment as far as magnitudes are concerned. The signs in either case are a triumph of the theory for both photon and pion transitions and verify that the S and D amplitudes have opposite sign.

For transitions from the $\underline{56} \mathrm{~L}^{\prime}=2$ to the ground state $\underline{56} \mathrm{~L}=0$ we also have in principle a large set of amplitudes for comparison with experiment. In practice the amplitudes are less well known, as seen in Table VIII. The quantities in the Table, as in the previous one, are matrix elements of $D_{+}^{3}+(1 / \sqrt{3}) D_{+}^{8}$ with signs appropriate to $\gamma \mathrm{p} \rightarrow \mathrm{N}^{*^{+}} \rightarrow \pi^{+} \mathrm{n}$ and $\gamma \mathrm{n} \rightarrow \mathrm{N}^{*^{\circ}} \rightarrow \pi^{-} \mathrm{p}$. For the $\pi \mathrm{NN}^{*}$ vertex we
express the two reduced matrix elements for $5 \underline{66} L^{\prime}=2 \rightarrow \underline{56} \mathrm{~L}=0$ pion decays as ${ }^{45}$

$$
\begin{align*}
& \left\langle\underline{56} \mathrm{~L}^{\prime}=2\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>=\frac{1}{5}(2 \mathrm{P}+3 \mathrm{~F})\right. \\
& \left.<\underline{56} \mathrm{~L}^{\prime}=2\left\|(3, \overline{3})_{1}-(\overline{3}, 3)_{-1}\right\| \underline{56} \mathrm{~L}=0\right\rangle=\frac{\sqrt{3}}{5}(\mathrm{P}-\mathrm{F}), \tag{48}
\end{align*}
$$

where the amplitudes $P$ and $F$ correspond to $\ell=1$ and 3 pion orbital angular momenta, respectively. The relative signs of P and F are the same (opposite) if the $(8,1)_{0}-(1,8)_{0}\left((3, \overline{3})_{1}-(\overline{3}, 3)_{-1}\right)$ matrix term dominates. The reaction ${ }^{46,47}$ $\pi N \rightarrow \pi \Delta$ indicates that $P$ and $F$ have the same sign, and we use this together with Table VI of Ref. 3 in constructing Table VIII. The "data" is again from Ref. 48.

To compare theory and experiment, we simplify the situation for the photon vertex by setting both the $<\underline{56} \mathrm{~L}^{\prime}=2\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>$ and < $56 \mathrm{~L}^{\prime}=2\left\|(\overline{3}, 3)_{-1}\right\| \underline{56} \mathrm{~L}=0>$ reduced matrix elements to zero. This leaves only $<\underline{56}, \mathrm{~L}^{\prime}=2\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>$ and $<\underline{56} \mathrm{~L}^{\prime}=2\left\|(3, \overline{3})_{1}\right\| 56 \mathrm{~L}=0>$, as would be the case in most quark model calculations. ${ }^{23,24}$ Rather than making a fit to all the amplitudes, we use the well measured $\gamma \mathrm{p} \rightarrow \mathrm{F}_{15}^{+}$amplitudes to fix the two reduced matrix elements, and then calculate the remaining amplitudes.

All the predicted signs agree with our previous results, ${ }^{5}$ and, with the possible exception of the $\mathrm{F}_{35}$ amplitude with $\lambda=3 / 2$, the experimentally welldetermined signs agree with the theory. In a previous analysis, ${ }^{51}$ both the $\mathrm{F}_{35}$ amplitudes also agreed. The signs of the $\mathrm{P}_{33}(2000)$ amplitudes, among the pwave $\pi \mathrm{N}$ resonances, provide some (marginal) support for the $P$ and $F$ amplitudes at the pion vertex having the same sign, as the $\pi N \rightarrow \pi \Delta$ analysis ${ }^{41,47}$ shows much more definitely.

The magnitudes of the predicted amplitudes are in fair agreement with what is observed. There is no need to allow $<\underline{56} \mathrm{~L}^{\prime}=2\left\|(8,1)_{0}-(1,8)_{0}\right\| 56 \mathrm{~L}=0>$ and $<\underline{56} L^{\prime}=2\left\|(\overrightarrow{3}, 3)_{-1}\right\| 56 \mathrm{~L}=0>$ to be non-zero. In fact, fitting all four reduced matrix elements to $\gamma \mathrm{p} \rightarrow \mathrm{F}_{15}^{+}$with $\lambda=1 / 2$ and $3 / 2, \gamma \mathrm{n} \rightarrow \mathrm{F}_{15}^{\mathrm{O}}$ with $\lambda=3 / 2$, and $\gamma \mathrm{p} \rightarrow \mathrm{P}_{33}^{+}$with $\lambda=1 / 2$ results in essentially the same predictions; the two additional reduced matrix elements have values more than an order of magnitude smaller than either $<\underline{56} \mathrm{~L}^{\prime}=2\left\|(8,1)_{0}+(1,8)_{0}\right\| 56 \mathrm{~L}=0>$ or $<\underline{56} \mathrm{~L}^{\prime}=2\left\|(3, \overline{3})_{1}\right\| \underline{56} \mathrm{~L}=0>$. The smallness of the $\lambda=3 / 2$ amplitude for $\gamma \mathrm{n} \rightarrow \mathrm{F}_{15}^{\mathrm{o}}$ by itself assures the strong constraint on the two additional reduced matrix elements

$$
\begin{equation*}
-\frac{4}{45}<\underline{56} \mathrm{~L}^{\prime}=2\left\|(\overline{3}, 3)_{-1}\right\| \underline{56} \mathrm{~L}=0>\simeq+\frac{4 \sqrt{2}}{45}<\underline{56} \mathrm{~L}^{\prime}=2\left\|(8,1)_{0}-(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0> \tag{49}
\end{equation*}
$$

There is thus fairly good evidence in this case that only the two reduced matrix elements found in the quark model are present at a significant strength, and, in particular, that equality of $<\underline{56} L^{\prime}=2\left\|(8,1)_{0}+(1,8)_{0}\right\| \underline{56} \mathrm{~L}=0>$ and $<56 L^{\prime}=2\left\|(8,1)_{0}-(1,8)_{0}\right\| 56 \mathrm{~L}=0>$ is ruled out.

Finally, we examine the transitions from a "radially excited" $56 \mathrm{~L}^{\prime}=0$ back to the ground state $\underline{56} \mathrm{~L}=0$. The $\underline{56} \mathrm{~L}^{\prime}=0$ includes the Roper resonance, $P_{11}(1470)$, and the $P_{33}(1718)$. We fit the one possible reduced matrix element, $<56 \mathrm{~L}^{\prime}=0\|(3, \overline{3})\| \underline{56} \mathrm{~L}=0>$, to the amplitude for $\gamma \mathrm{p} \rightarrow \mathrm{P}_{11}^{+}(1470)$, and predict the other amplitudes in Table IX using the $56 \mathrm{~L}^{\prime}=0 \rightarrow \underline{56} \mathrm{~L}=0$ matrix elements from Table IV. Again the signs are those in $\gamma p \rightarrow \pi^{+} n$ and $\gamma n \rightarrow \pi^{-} p$. The experimental results of both the Berkeley ${ }^{48}$ and Lancaster ${ }^{49}$ analyses are shown, there being some discrepancy between the two. It appears, at least from the latter
analysis, that both the signs and magnitudes of the experimental and theoretical amplitudes are in agreement. Note that this is a case where the explicit quark model_results of Feynman et al. ${ }^{24}$ fail by predicting the wrong sign ${ }^{48,51}$ for the $\mathrm{P}_{11}(1470)$ excitation.

## V. SUMMARY AND CONCLUSION

The operator $V$, which by definition takes us from a current to constituent quark basis, contains in principle all the information about matrix elements of the weak and electromagnetic currents when taken between hadron states, assuming that the hadrons can be treated as if constructed out of (constituent) quarks. Lacking a complete knowledge of $V$, we have abstracted only certain of its algebraic properties from the free quark model and assumed them to hold in the real world. In particular, in this paper we have abstracted properties of the operators $\mathrm{V}^{-1} \mathrm{D}_{ \pm}^{\alpha} \mathrm{V}$, which correspond to those which induce real photon transitions between hadrons.

In our case, abstraction from the free quark model leads to $\mathrm{V}^{-1} \mathrm{D}_{+}^{\alpha} \mathrm{V}$ being assumed to be the sum of four terms which transform as: $\left\{(8,1)_{0}+(1,8)_{0}, 1\right\}$, $\left\{(3, \overline{3})_{1}, 0\right\},\left\{(8,1)_{0}-(1,8)_{0}, 1\right\}$, and $\left\{(\overline{3}, 3)_{-1}, 2\right\}$, all of which belong to $35{ }^{\prime}$ s of the full $\mathrm{SU}(6)_{\mathrm{W}}$ of currents. In Section II we have shown how matrix elements of $D_{+}^{3}+(1 / \sqrt{3}) D_{+}^{8}$ are related to real photon amplitudes and how they may be related to a sum of $\left(\mathrm{SU}(6)_{\mathrm{W}}\right)$ Clebsch-Gordan coefficients times at most four reduced matrix elements for photon transitions from one hadronic $\operatorname{SU}(6)_{W}$ multiplet to another. We have also shown that the theory leads to multipole selection rules, a particular example of which is the old $\operatorname{SU}(6)$ result ${ }^{4}$ that the transition from the nucleon to $3-3$ resonance should be magnetic dipole in character. In fact, we may generally express the four reduced matrix elements for transitions between two given multiplets in terms of four multipole amplitudes, two electric (of the same multipolarity) and two magnetic. These selection rules yield very
interesting predictions, which may be subject to a qualitative experimental test in that low values of $j_{\gamma}$ (or $\ell$ for pions) are forbidden for $L^{\prime} \geq 3 \rightarrow L=0$ transitions, even though they are otherwise allowed by spin-parity considerations and favored by angular momentum barrier arguments.

When applied to mesons there are many amplitudes which are related, but little to compare with experiment besides the transitions between the vector and pseudoscalar mesons, both of which lie in the 35 and $\underline{1}$ with $\mathrm{L}=0$. The available data is consistent with the theory, but little else can be said at the moment.

For baryons on the other hand, we have years of experimental effort that has been devoted to pion photoproduction in the resonance region, from which baryon electromagnetic couplings may be extracted by phase shift analysis. For the $\underline{70}$ $L=1$ baryon states, not only do we find agreement of all the experimentally well determined signs with the theory, but the photopion matrix elements, which contain information on both the $\gamma \mathrm{NN}^{*}$ and $\pi \mathrm{NN}^{*}$ vertices, indicate that the S and D wave amplitudes at the pion vertex have opposite sign. This is in agreement with the results ${ }^{46,47}$ from the reaction $\pi N \rightarrow \pi \Delta$. For the $\underline{56} \mathrm{~L}=2$ baryon resonances, again all signs agree with the theory, except for possibly one of the $\gamma \mathrm{N} \rightarrow \mathrm{F}_{35}^{+}$ amplitudes. There is also an indication from $\gamma \mathrm{N} \rightarrow \pi \mathrm{N}$ that the P and F amplitudes at the $\pi N N^{*}$ vertex have the same sign, in agreement with results ${ }^{46,47}$ from $\pi N \rightarrow \pi \Delta$. While the signs are in good shape, the magnitudes, particularly for $\underline{70} \mathrm{~L}=1 \rightarrow \underline{56} \mathrm{~L}=0$ transitions, leave something to be desired. Given the uncertainties in the experimental analyses, however, we feel the present situation is fairly satisfactory.

The general outlook then is extremely good. Between the phase shift analyses of $\pi \mathrm{N} \rightarrow \pi \Delta$ and $\gamma \mathrm{N} \rightarrow \pi \mathrm{N}$, more than 25 signs predicted by the theory agree with experiment. For the first time we have some good evidence that not only is the
multiplet structure of the quark model found in Nature, but further that the wave functions of the states resemble those of the constituent quark model, in that the relative signs (and more roughly, magnitudes) of amplitudes are correctly predicted. However, neither the results at the $\pi N^{\prime} N^{*}$ nor $\gamma N_{N}{ }^{*}$ vertices corresponds to the hypothesis of $\operatorname{SU}(6)_{W}$ conservation, the most direct and powerful evidence being the signs and magnitudes of amplitudes for $70 \mathrm{~L}^{\prime}=1$ baryon resonances to decay into $\pi \mathrm{N}, \pi \Delta$ and $\gamma \mathrm{N}$. The predictions resulting from the quark model, ${ }^{23,24}$ where the reduced matrix elements are explicitly calculable, are wrong in places also - in particular in the signs of pion transition amplitudes for $56 \mathrm{~L}^{\prime}=2$ to $\underline{56} \mathrm{~L}=0$ baryons and in the signs of photoproduction amplitudes for $\gamma \mathrm{N} \rightarrow \mathrm{P}_{11}(1470)$ $\rightarrow \pi \mathrm{N}$ 。

With the success of the theory, it may now be used as a tool to help in classifying new resonances into multiplets by using information on their signs in $\pi \mathrm{N} \rightarrow \pi \Delta$ and $\gamma \mathrm{N} \rightarrow \pi \mathrm{N}$. What is still needed is a dynamics, or possibly an even higher symmetry, which will correctly give the magnitude and sign of the reduced matrix elements. This, and the extension to $q^{2} \neq 0$, remain as important problems for the future。

## Acknowledgments

We thank F. Close, M. Kugler, S. Meshkov, J. Rosner, J. Weyers and J. Willemsen for valuable discussions during the course of this work.

TABLE I

- Matrix elements for photon transitions among $\underline{35}$ and $\underline{1} \mathrm{~L}=0$ states. The $\omega$ and $\phi$ are assumed to be ideally mixed, while the $\eta$ and $X^{0}$ are taken as the $\operatorname{SU}(3)$ octet and singlet pseudoscalar mesons (see text).

Coefficient of

## Transition

$\left\langle\underline{35} \mathrm{~L}^{\prime}=0\left\|(3,3)_{1}\right\| \underline{35} \mathrm{~L}=0>\right.$

$$
\begin{array}{lc}
\omega \rightarrow \gamma \pi & \sqrt{3} / 6 \\
\rho \rightarrow \gamma \pi & \sqrt{3} / 18 \\
\phi \rightarrow \gamma \pi & 0
\end{array}
$$

$$
\rho \rightarrow \gamma \eta
$$

$$
1 / 6
$$

$\omega \rightarrow \gamma \eta$
1/18
$\phi \rightarrow \gamma \eta$
$-\sqrt{2} / 9$
$X^{0} \rightarrow \gamma \rho$
$\sqrt{2} / 6$
$X^{0} \rightarrow \gamma \omega$
$\sqrt{2} / 18$
$\phi \rightarrow \gamma \mathrm{X}^{0}$
$1 / 9$

TABLE II
Predicted and experimental widths for radiative transitions among $\underline{35}$ and $1 \mathrm{~L}=0$ mesons.

| Decay | Predicted Width (KeV) (no mixing) | Predicted Width (KeV) $\left(\theta_{\mathrm{P}}=-10.5^{\circ}\right)$ | $\begin{gathered} \text { Experimental } \\ \text { Width }(\mathrm{KeV}){ }^{31,32} \end{gathered}$ |
| :---: | :---: | :---: | :---: |
| $\omega \rightarrow \gamma \pi$ | 890 (input) | 890 (input) | $890 \pm 90$ |
| $\rho \rightarrow \gamma \pi$ | 94 | 94 | $<730$ |
| $\phi \rightarrow \gamma \pi$ | 0 | 0 | $<14$ |
| $\rho \rightarrow \gamma \eta$ | 37 | 57 | < 160 |
| $\omega \rightarrow \gamma \eta$ | 5 | 7 | < 49 |
| $\phi \rightarrow \gamma \eta$ | 230 | 170 | $126 \pm 46$ |
| $\mathrm{X}^{0} \rightarrow \gamma \rho$ | 160 | 120 | $0.26 \Gamma\left(\mathrm{X}^{\mathrm{O}} \rightarrow\right.$ all $)$ |
| $\mathrm{X}^{0} \rightarrow \gamma \omega$ | 15 | 11 |  |
| $\phi \rightarrow \gamma \mathrm{X}^{0}$ | 0.5 | 0.6 |  |

TABLE III
Photon transition amplitudes from non-strange mesons ${ }^{36}$ with $L^{\prime}=1$ and $J_{z}=\lambda$ to those with $L=0$ and $J_{z}=\lambda-1$ 。The $\omega, f, D$, and $\sigma$ are assumed to be ideal mixtures of singlets and octets, so as to be composed purely of nonstrange quarks; the $\eta$ and H are purely octet, and the $\mathrm{X}^{\mathrm{o}}$ a pure singlet. Zweig's rule ${ }^{29}$ is used to relate $\mathrm{SU}(6)_{\mathrm{W}} \underline{35}$ and $\underline{1}$ reduced matrix elements (see text), and forbids decays like $A_{2}, A_{1}, \delta, f, D, \sigma \rightarrow \gamma \phi$ and $\mathrm{f}^{\prime} \rightarrow \gamma \rho$ or $\gamma \omega$ 。
