Fermilab Single Arm Spectrometer Group ${ }^{\dagger}$

#### Abstract

The ratio of $\pi^{+} p$ to $p p$ elastic scattering is found to be smoothly varying over the range $-t=0.03$ to $0.4 \mathrm{GeV}^{2}$. It is well fit by a single exponential, indicating the forward behavior must be quite similar for the two reactions.

It has been known for sometime that the logarithmic slope for pp elastic scattering is steeper at small momentum transfers, $-\mathrm{t} \leqslant 0.15 \mathrm{GeV}^{2}$, than at 1 larger momentum transfers. Although some increase at small $t$ is expected on the basis of quadratic fits of the type

$$
\frac{d \sigma}{d t}=A e^{B t}+C t^{2}
$$

[^0]2
a high statistics experiment at the CERN ISR indicated a break, or more rapid change in slope, near $-t=0.15 \mathrm{GeV}^{2}$ of about $1.5 \mathrm{GeV}^{-2}$. At Fermilab energies a comparison of the slopes observed in the gas jet experiment ${ }^{3}$ in the range $0.005 \leq-t \leq 0.09 \mathrm{GeV}^{2}$ with our ${ }^{4}$ and other ${ }^{5}$ results at an effective $-t=0.2 \mathrm{GeV}^{2}$ gives a slope change of about $1.3 \mathrm{GeV}^{-2}$. This can be compared with a change of $0.8 \mathrm{GeV}^{-2}$ expected on the basis of the quadratic fits to the spectrometer data, where typically $\mathrm{C}=2$ and is positive.

To further investigate the small $t$ behavior of the $\pi^{+} p$ and $p p$ elastic scattering, systematic errors must be reduced to a minimum. To this end, we have examined the ratio

$$
\mathrm{R}=\frac{\mathrm{d} \sigma}{\mathrm{dt}}\left(\pi^{+}{\mathrm{p} \rightarrow \pi^{+}}^{+}\right) / \frac{\mathrm{d} \sigma}{\mathrm{dt}}(\mathrm{pp} \rightarrow \dot{\mathrm{p}} \mathrm{p})
$$

in the region $-t \leq 0.4 \mathrm{GeV}^{2}$. Since the $\pi^{+} p$ and $p p$ data were taken simultaneously, this ratio is insensitive to many systematic effects and gives a highly reliable result on the relative behavior of the two processes.

The experiment used the Fermilab M6E high precision beam line and the Single Arm Spectrometer Facility to detect scattered particles. Proton and $\pi^{+}$ scattering off hydrogen were measured simultaneously under identical conditions using the same acceptance and detectors. The apparatus has been previously described ${ }^{4}$ and we will only discuss those features germane to the $\pi^{+} / \mathrm{p}$ ratio.

The beam line contained scintillation hodoscopes to tag the incoming momenta and angles. Pions were identified with a threshold gas Cerenkov counter, while protons were identified with a gas differential counter, and kaons with a DISC counter. A pion trigger required both that the threshold counter fired and that no proton or kaon accompanied the pion. A proton trigger required a proton coincidence and no accompanying pion or kaon. The elastic scattering angle was varied by changing the angle of incidence of the beam on the target, the $t$ range
being covered in a series of steps. No Cerenkov information was used in the trigger requirement for particles scattered into the spectrometer, leaving the trigger equally efficient for protons and pions aside from losses of pions from decays. To check that the beam line trigger requirements introduced no systematic biases, a sample of beam triggers was simultaneously recorded along with the beam spectrometer events. The phase space distribution of these beam triggers could be determined from the hodoscope information and was essentially the same for pions and protons.

Several potential sources of error were considered. The momentum resolution ( $0.1 \%$ ) was sufficient for the elastic scattering peak to be almost completely separated from the inelastic processes with at most a few percent contamination. Since the inelastic cross sections in the neighborhood of the elastic peak scale 6 proportional to the elastic cross sections, the effects of this contamination cancel in the ratio. Another source of potential error arose from possible changes in the $\mu$ and e contaminations in the beam. This small contamination was misidentified as pions by the Cerenkov trigger requirement and could thus cause a variation in the pion cross section. The contamination was checked periodically, amounted to a few percent and remained constant to better than $1 \%$. A possible source of error came from two beam particles separated in time by less than the resolving time of the electronics (same rf bucket). This was largely eliminated by the requirements of "one particle only" in the beam hodoscopes and at most $1 \%$ of the triggers contained two particles. Radiative and target empty corrections were made and amounted to at most $10 \%$. Estimates were made for Coulomb interference effects and were never more than $3 \%$. Corrections of a few percent were made to the ratios to take into account double scattering pion Bremsstrahlung, pion decay, and target attenuation. These corrections are $\operatorname{small}(54 \%)$ and only slowly varying in $t$.

Accordingly, we believe the systematic errors affecting the $t$ dependence of cross section ratios were less than $1.5 \%$.

Figure 1 shows plots of the ratios of $\pi^{+} p$ to $p p$ scattering at each energy. It is clear from visual inspection that a simple exponential fit provides an excellent representation of the data. The use of more complex fitting functions does not significantly improve the quality of the fits. The results of fitting to various $t$ ranges are shown in Table $I$.

Figure 2 compares the exponential slopes found at small -t ( 0.03 to $0.15 \mathrm{GeV}^{2}$ ) with those at larger $-\mathrm{t}\left(0.15\right.$ to $\left.0.40 \mathrm{GeV}^{2}\right)$. Although the small -t slope has considerable statistical uncertainty and some fluctuations, the two slopes agree with one another to within $\pm 0.25 \mathrm{GeV}^{2}$ when averaged over momentum. Given this result and the smoothness of the $\pi^{+} / \mathrm{p}$ ratios, we conclude that structure, if any, must be quite similar for the two reactions in this $t$ region.

We would like to express our thanks to the many people at Fermi National Accelerator who have contributed to the successful operation of the Single Arm Spectrometer and of the accelerator and beam lines. We would also like to express appreciation to our technical support personnel for their invaluable assistance.

${ }^{7}$ In a separate analysis of the $\pi^{+} p, \pi^{-} p$ and $p p$ elastic data from this experiment, it was found that at 50 and $70 \mathrm{GeV} / \mathrm{c}$ the forward slopes of these processes increase by typically $(0.3 \pm 0.2) \mathrm{GeV}^{-2}$ over that given by a quadratic fit to the data at $-t>0.12 \mathrm{GeV}^{2}$.
