SLAC National Accelerator Laboratory
E-mail: mokhtar@slac.stanford.edu

The BABAR Collaboration performed a search for $\xi(2220)$ production in the initial-state radiation process $e^{+} e^{-} \rightarrow \gamma J / \psi, J / \psi \rightarrow \gamma K^{+} K^{-}$or $J / \psi \rightarrow \gamma K_{S}^{0} K_{S}^{0}$. No evidence for the $\xi(2220)$ resonance has been found. The $90 \%$ confidence level upper limits on the product of branching fractions are sensitive to the spin and helicity hypotheses. These upper limits are of the order $10^{-5}$, below the values reported in previous experiments. Also at $B A B A R$, the decays $B \rightarrow J / \psi \pi^{+} \pi^{-} \pi^{0} K$ are studied to search for the decay $X(3872) \rightarrow J / \psi \omega$. This search yields a four standard deviation evidence for $X(3872) \rightarrow J / \psi \omega$, with product branching fractions of $\mathscr{B}\left(B^{+} \rightarrow X(3872) K^{+}\right) \times \mathscr{B}(X(3872) \rightarrow J / \psi \omega)=[0.6 \pm 0.2($ stat $) \pm 0.1($ syst $)] \times 10^{-5}$, and $\mathscr{B}\left(B^{0} \rightarrow X(3872) K^{0}\right) \times \mathscr{B}(X(3872) \rightarrow J / \psi \omega)=[0.6 \pm 0.3($ stat $) \pm 0.1($ syst $)] \times 10^{-5}$. A detailed study of the $\pi^{+} \pi^{-} \pi^{0}$ mass distribution from $X$ (3872) decay favors a negative-parity assignment but does not rule out the positive-parity hypothesis.

35th International Conference of High Energy Physics - ICHEP2010,
July 22-28, 2010
Paris France

[^0]
## 1. Introduction

The $\xi(2220)$ resonance is a glue-ball candidate whose existence is not yet established. The $X(3872)$ has been observed in several decay modes and by several Collaborations. However, the nature of the $X(3872)$ is still not yet understood. We present the BABAR results on the search for $\xi(2220)$ in radiative $J / \psi$ decays [迆, and on the evidence for the decay $X(3872) \rightarrow J / \psi \omega\left[\begin{array}{l}\text { [ }] .\end{array}\right.$

## 2. Search for $\xi(2220)$ in Radiative $J / \psi$ Decays

In 1986, the Mark III Collaboration reported [3]] a narrow resonance with a mass of $\sim 2.2$ $\mathrm{GeV} / c^{2}$ in the radiative decay $J / \psi \rightarrow \gamma \xi(2220), \xi(2220) \rightarrow K^{+} K^{-}$and $\xi(2220) \rightarrow K_{S}^{0} K_{S}^{0}$. A 3.6 and 4.7 standard deviation significance for $J / \psi \rightarrow \gamma K^{+} K^{-}$and $J / \psi \rightarrow \gamma K_{S}^{0} K_{S}^{0}$ modes were reported. The BES Collaboration also reported evidence for the $\xi(2220)$ in $J / \psi$ radiative decays at a comparable level of significance [ 4$]$. Moreover, there are indications for a similar structure in $\pi^{-} p$ and $K^{-} p$ collisions [5], 6, 7]. On the other hand, searches for $\xi(2220)$ in $p \bar{p}$ collisions [8, 97], or two photon production [10, 11], have been inconclusive.

In a recent BABAR search [】], the initial-state radiation (ISR) events $e^{+} e^{-} \rightarrow \gamma_{\text {ISR }} J / \psi, J / \psi \rightarrow$ $\gamma K K$ ( $K K$ indicates $K^{+} K^{-}$or $K_{S}^{0} K_{S}^{0}$ ), were studied to search for the $\xi(2220)$. The BABAR data sample is equivalent to an integrated luminosity of $460 \mathrm{fb}^{-1}$, recorded at or slightly below 10.58 GeV .

The $\gamma K^{+} K^{-}$and $\gamma K_{S}^{0} K_{S}^{0}$ mass distributions are shown in Fig. [1] where a large $J / \psi$ signal is observed in both decay modes. The background under the signal arises mainly from partially reconstructed $J / \psi \rightarrow K K X$ or $e^{+} e^{-} \rightarrow q \bar{q} \gamma_{\text {ISR }}$ events, where $X$ can be any final state system and $q=u, d, s, c$. The $\gamma K K$ candidates are required to originate from a common vertex and are kinematically constrained to the $J / \psi$ nominal mass. Each $K_{S}^{0}$ candidate in the decay $J / \psi \rightarrow \gamma K_{S}^{0} K_{S}^{0}$ is reconstructed from two oppositely charged tracks identified as pions. The photon emitted from the $J / \psi$ has a minimum energy of 300 MeV .

The $K^{+} K^{-}$and $K_{S}^{0} K_{S}^{0}$ mass distributions are shown in Fig. 8 . The inclusive background and background events corresponding to $J / \psi \rightarrow \gamma f_{2}^{\prime}(1525)$ and $J / \psi \rightarrow \gamma f_{0}(1710)$, are present. The small data excess at $\sim 1.25 \mathrm{GeV} / c^{2}$ in the charged mode may be due to the process $J / \psi \rightarrow \rho^{0} \pi^{0}$, with $\rho^{0} \rightarrow \pi^{+} \pi^{-}$, where both pions are misidentified as kaons, and one of the photons from the $\pi^{0}$ is undetected. To extract the $\xi(2220)$ yield, unbinned-maximum likelihood fits in the range $1.9 \leq$ $m_{K K} \leq 2.6 \mathrm{GeV} / c^{2}$ are performed. The signal is described as a Breit-Wigner function convolved with a Gaussian resolution function. The background is parametrized as a second-order Chebychev polynomial. Both the mass and width of the $\boldsymbol{\xi}(2220)$ are fixed. There is no evidence for $\boldsymbol{\xi}(2220)$ state. The upper limits on the product of branching fractions depend on the spin and helicity assignment. For all hypotheses of spin and helicity, the $90 \%$ confidence level upper limits for the $J / \psi \rightarrow \gamma \xi(2220), \xi(2220) \rightarrow K K$ product branching fractions are in the range $(1.2-3.6) \times 10^{-5}$, smaller or close to the values reported by the Mark III Collaboration.

## 3. Evidence for $X(3872) \rightarrow J / \psi \omega$

With the discovery [12] of the $X(3872)$ by the Belle Collaboration in 2003, interest in charmonium spectroscopy has been renewed. Confirmation of this state was obtained by CDF, D0, and

Figure 1: The mass distribution of (a) $\gamma K^{+} K^{-}$and (b) $\gamma K_{S}^{0} K_{S}^{0}$ for the final sample. The dots represent the data and the histograms show the fits to the data when requiring a fit probability above 0.01 . The shaded histograms represent the estimated background.

Figure 2: The fitted mass distribution for (a) $K^{+} K^{-}$and (b) $K_{S}^{0} K_{S}^{0}$. The contributions of the inclusive background (open histograms), $J / \psi \rightarrow \gamma f_{2}^{\prime}(1525)$ (cross hatched histograms), and $J / \psi \rightarrow \gamma f_{0}(1710)$ (hatched histograms) are shown. The insets show the fit results in the $\xi(2220)$ region.
$B A B A R$ experiments [13, 14, 15, 16, 17]. Since then, several other charmonium-like states have been discovered [18]. The $X(3872)$ is the most-studied state and the only one which has been identified in more than one decay mode, assuming that the reported $X, Y$, and $Z$ states are actually different states. A great deal of effort has been expended to understand the nature of the $X(3872)$ especially its spin-parity assignment $\left(J^{P C}\right)$. So far, $J^{P C}=1^{++}$or $2^{-+}$can be assigned to the $X(3872)$. The radiative decays $X(3872) \rightarrow \gamma J / \psi$ [19, 20, 21] and $X(3872) \rightarrow \gamma \psi(2 S)$ [21] indicate positive $C$ parity. At BABAR, no charged-partner for the $X(3872)$ has been observed [22]. This establishes $I=0$.

In a previous BABAR analysis [23] of $B \rightarrow J / \psi \omega K$ decays, the observation of the $Y(3940)$ meson in the decay $Y(3940) \rightarrow J / \psi \omega$, as reported by the Belle Collaboration [24], was confirmed. In this analysis, $\omega \rightarrow \pi^{+} \pi^{-} \pi^{0}(\omega \rightarrow 3 \pi)$ candidates were required to satisfy $0.7695 \leq m_{3 \pi} \leq$ $0.7965 \mathrm{GeV} / c^{2}$, and no evidence for the decay $X(3872) \rightarrow J / \psi \omega$ was found.

Figure 3: The $J / \psi \omega$ mass distribution for (a) $B^{+} \rightarrow J / \psi \omega K^{+}$and (b) $B^{0} \rightarrow J / \psi \omega K_{S}^{0}$ decays; (c) shows the region $m_{J / \psi \omega}<3.95 \mathrm{GeV} / c^{2}$ of (a). The curves show the fit results and the individual fit contributions.

In a more recent $B A B A R$ analysis [2] the same decay mode $B \rightarrow J / \psi \omega K$ has been revisited using a slightly larger dataset and extending the range of the $\omega$-mass region to $0.74 \leq m_{3 \pi} \leq 0.7965$ $\mathrm{GeV} / c^{2}$. All other selection criteria are the same as in the previous analysis [23]. The efficiency as a function of $m_{J / \psi \omega}$ varies between 5 and $7 \%$, and the mass resolution degrades from $6.5 \mathrm{MeV} / c^{2}$ to $9 \mathrm{MeV} / c^{2}$, over the accessible mass range. The $J / \psi \omega$ mass $\left(m_{J / \psi \omega}\right)$ distribution, after background subtraction, shows a clear signal corresponding to $Y(3940) \rightarrow J / \psi \omega$, and evidence for $X(3872) \rightarrow$ $J / \psi \omega$. These signals are present in both $B^{+}$and $B^{0}$ samples [25] as shown in Fig. B. The $m_{J / \psi \omega}$ distributions are fitted simultaneously after correcting for efficiency and branching fractions. The function used in the fit has three components: an $X(3872)$ component which is a Gaussian function with fixed $\sigma=6.7 \mathrm{MeV} / c^{2} ;$ a $Y(3940)$ contribution described by a relativistic $S$-wave Beit-Wigner function; and a nonresonant contribution given by a broad Gaussian function multiplied by $m_{J / \psi \omega}$. The $Y(3940)$ and nonresonant components are multiplied by the phase space factor $p q$, where $p$ is the kaon momentum in the $B$ rest frame and $q$ is the $J / \psi$ momentum in the $J / \psi 3 \pi$ system. A good fit is obtained ( $\chi^{2} / N D F=54.7 / 51$ ). The fit results are summarized in Table [1.

When combined with the product branching fraction for $B \rightarrow X(3872) K, X(3872) \rightarrow J / \psi \pi^{+} \pi^{-}$ [17], the BABAR ratio of branching fractions $\mathscr{B}(X(3872) \rightarrow J / \psi \omega) / \mathscr{B}\left(X(3872) \rightarrow J / \psi \pi^{+} \pi^{-}\right)$has the value $0.7 \pm 0.3$ and $1.7 \pm 1.3$ (combined uncertainties) for $B^{+}$and $B^{0}$, respectively. These results provide an average ratio of $0.8 \pm 0.3$, which is in agreement with the Belle result [19] of $1.0 \pm 0.4 \pm 0.3$.

To judge whether the $3 \pi$ originate from $\omega$ decays or not, $3 \pi$ events in the mass range of $\omega$ and $\eta$ signals are selected. The sum of the $\omega$-Dalitz-plot weights [23] is consistent with the number of $3 \pi$ events around the $\omega$ signal. The same sum for the events around $\eta$ signal is consistent with zero. The sum for the weighted $3 \pi$ mass distribution associated with the $X(3872)$ is consistent with the number of events observed. This justifies the $\omega$ interpretation of the events in the $X(3872)$ region.

| Quantity | Measurement |
| :--- | :--- |
| Mass $X(3872)\left(\mathrm{MeV} / c^{2}\right)$ | $3873.0_{-1.6}^{+1.8} \pm 1.3$ |
| Mass $Y(3940)\left(\mathrm{MeV} / c^{2}\right)$ | $3919.1_{-3.4}^{+3.8} \pm 2.0$ |
| Width $Y(3940)(\mathrm{MeV})$ | $31_{-8}^{+10} \pm 5$ |
| $\mathscr{B}\left(B^{0} \rightarrow X(3872) K^{0}\right) \times \mathscr{B}(X(3872) \rightarrow J / \psi \omega)\left(10^{-5}\right)$ | $0.6 \pm 0.3 \pm 0.1$ |
| $\mathscr{B}\left(B^{+} \rightarrow X(3872) K^{+}\right) \times \mathscr{B}(X(3872) \rightarrow J / \psi \omega)\left(10^{-5}\right)$ | $0.6 \pm 0.2 \pm 0.1$ |
| $\mathscr{B}\left(B^{0} \rightarrow Y(3940) K^{0}\right) \times \mathscr{B}(Y(3940) \rightarrow J / \psi \omega)\left(10^{-5}\right)$ | $2.1 \pm 0.9 \pm 0.3$ |
| $\mathscr{B}\left(B^{+} \rightarrow Y(3940) K^{+}\right) \times \mathscr{B}(Y(3940) \rightarrow J / \psi \omega)\left(10^{-5}\right)$ | $3.0_{-0.6}^{+0.7}{ }_{-0.3}^{+0.5}$ |
| $\mathscr{B}\left(B^{0} \rightarrow J / \psi \omega K^{0}\right)\left(10^{-4}\right)$ | $2.3 \pm 0.3 \pm 0.3$ |
| $\mathscr{B}\left(B^{+} \rightarrow J / \psi \omega K^{+}\right)\left(10^{-4}\right)$ | $3.2 \pm 0.1_{-0.3}^{+0.6}$ |
| $R_{X}$ (ratio of $B^{0}$ to $B^{+}$branching fraction to $\left.B \rightarrow X(3872) K\right)$ | $1.0_{-0.6}^{+0.0}+0.2$ |
| $R_{Y}$ (ratio of $B^{0}$ to $B^{+}$branching fraction to $\left.B \rightarrow Y(3940) K\right)$ | $0.7_{-0.3}^{+0.4} \pm 0.1$ |
| $R_{\mathrm{NR}}$ (ratio of $B^{0}$ to $B^{+}$branching fraction to nonresonant $\left.J / \psi \omega K\right)$ | $0.7 \pm 0.1 \pm 0.1$ |

Table 1: Results obtained from the most recent $B A B A R$ analysis of $B \rightarrow J / \psi \omega K$ decays [ 2 Z$]$.

Figure 4: The $m_{3 \pi}$ distribution for events that satisfy $3.8625 \leq m_{J / \psi \omega} \leq 3.8825 \mathrm{GeV} / c^{2}$ for (a) $B^{+}$, (b) $B^{0}$, and (c) combined. The vertical line shows the $\omega$ nominal mass. In (c), the solid (dashed) histogram shows the $P$-wave ( $S$-wave) Monte Carlo events normalized to the number of data events.

The events with $3.8625 \leq m_{J / \psi \omega} \leq 3.8825 \mathrm{GeV} / c^{2}$ are selected for further investigation of the $X(3872)$ parity. For those events, the $m_{3 \pi}$ distributions are shown in Fig. $\forall$ and compared with the Monte Carlo simulation for different spin assignment. The $P$-wave assignment is favored $\left(\chi^{2} / N D F=3.53 / 5\right)$ over the $S$-wave $\left(\chi^{2} / N D F=10.17 / 5\right)$, hence $J^{P}=2^{-}$is favored over $J^{P}=$ $1^{+}$, but the latter cannot be ruled out. Clearly this analysis would benefit greatly from the much larger datasets available from future facilities such as the Super $B$-factories.

## 4. Acknowledgments

I would like to thank my BABAR Collaborators, especially Vera Lüth, Bill Dunwoodie, and Bryan Fulsom, for their contributions to the presentation at the ICHEP meeting, and to these proceedings.
