#### Abstract

The spin dependence of $\psi$ photoproduction is analyzed in the context of a quark-gluon model. The $\psi$ is treated as a nonrelativistic bound state of a ce pair, with exchange of two colored vector gluons to the spinless target. Effects due to the binding of the ce pair are ignored, resulting in a simple, parameter-free model for $\psi$ photoproduction. A detailed calculation of the helicity amplitudes and density matrix elements to leading order in $s$ is given. The scalar gluon exchange case is also analyzed, and the decay angular distribution for $\psi \rightarrow \varrho^{+}{ }^{-}{ }^{-}$is discussed in terms of the $\psi$ density matrix.

(Submitted for publication.)

[^0]
## I．INTRODUCTION

\＃゙photoproduction exhibits the characteristics of diffraction or Pomeron ex－ change，namely，an almost constant total cross section for asymptotic energies and an exponentially decreasing differential cross section．This kind of be－ havior was also found to hold in photoproduction of $\rho, \omega$ ，and $\phi$ ．Experimen－ tally，the latter processes conserve s－channel helicity and，indeed，it is com－ monly thought that s－channel helicity conservation（SCHC）is an intrinsic char－ acteristic of Pomeron exchange。

In previous papers ${ }^{1,2}$ we have investigated whether SCHC also holds true for $\psi$ photoproduction by undertaking a systematic spin analysis of various models for $\psi$ photoproduction at asymptotic energies and near threshold．Two of the models are phenomenological parametrizations of the data for $\rho$ photopro－ duction，analytically continued in the vector meson mass to $m_{V}=m_{\psi^{\circ}}$ Alterna－ tively，we assumed the $\psi$ to consist of a pair of constituents interacting with the nucleon via vector or scalar gluon exchange。 The main result of this analysis is that at asymptotic energies all models predict SCHC，whereas at moderate en－ ergies，substantial violation of SCHC is possible．In particular，however，in this subasymptotic region vector gluon exchange obeys SCHC almost exactly，in contrast to the predictions of all other models．

This fact is especially significant in that the two vector gluon exchange model is perhaps the most attractive model we consider．When combined with a relativistic bound－state interpretation of the $\psi$ ，it provides a well－defined，physi－ cally reasonable＂Quantum Chromodynamics＂－type mechanism for photoproduc－ tion．Calculations can be carried out which are limited in pre－ cision only by the technical difficulties involved in dealing with Feynman graphs． For these reasons，we devote the bulk of the present work to a detailed
examination of the two-gluon exchange picture. We include a complete discus-sion-of the calculation of the helicity amplitudes to leading order in $s$, as well as detailed results for the density matrix. For a comparison of the predictions of various photoproduction models we refer the reader to Refs. 1 and 2 .

The paper is organized as follows. In Section II we discuss the connection between the decay angular distribution for $\gamma \mathrm{N} \rightarrow \psi \mathrm{N}\left(\psi \rightarrow \mathrm{e}^{+} \mathrm{e}^{-}\right)$and the density matrix. We consider the case of the most general $\psi \mathrm{e}^{+} \mathrm{e}^{-}$coupling, and its reduction to a purely transverse coupling. The scalar and vector gluon exchange models are introduced in Section III, and calculation of the resulting Feynman graphs is discussed. Section IV presents the results of the analysis for helicity amplitudes and density matrix elements. Conclusions appear in Section V. Finally, many of the technical details of the two-gluon exchange calculation are reserved for the appendices.

## II. ANGULAR DISTRIBUTION AND DENSITY MATRIX

The spin density matrix of the created vector meson $V$ in the process $\gamma \mathbb{N} \rightarrow$ VN determines the angular distribution of its decay products. Since $\psi \rightarrow e^{+} e^{-}, \mu^{+} \mu^{-}$are the most important single $\psi$-decay modes, these can be used to determine the helicity of the created $\psi$-meson in the same way as the $\pi^{+} \pi^{-}$ mode in $\rho$-photoproduction contains information about the spin of the created $\rho$ meson. In this section we therefore analyze the decay angular distribution for $V \rightarrow e^{+} e^{-}-1$

The process we are describing is shown in Fig. 1 and its matrix element can be written as a product

$$
\begin{equation*}
\left\langle l^{+} l^{-} \mathrm{N}_{2}\right| \mathrm{T}\left|\gamma \mathrm{~N}_{1}\right\rangle=\left\langle l^{+} l^{-}\right| \mathrm{M}|\mathrm{~V}\rangle\langle\mathrm{V}| \mathrm{T}|\gamma\rangle . \tag{2,1}
\end{equation*}
$$

The first term describes the decay $\mathrm{V} \rightarrow \ell^{+} \ell^{-}$whereas the second is the helicity amplitude for $\gamma \mathrm{N} \rightarrow \mathrm{VN}$. The decay angular distribution of the vector meson in its rest frame is obtained by squaring the matrix element and summing over the helicities

$$
\begin{equation*}
\frac{\mathrm{dN}}{\mathrm{~d} \cos \theta \mathrm{~d} \phi} \equiv \mathrm{~W}(\theta, \phi)=\sum_{\mathrm{VV}}{ }^{\prime} \sigma_{\mathrm{VV}^{\prime}}(\theta, \phi) \circ \rho_{\mathrm{VV}^{\prime}} \tag{2.2}
\end{equation*}
$$

Here $\rho_{\mathrm{VV}^{\prime}}$ is the spin density matrix for $\gamma \mathrm{N} \rightarrow \mathrm{VN}$; it is connected with the photon density matrix and the helicity amplitudes through

$$
\begin{equation*}
\rho_{\mathrm{VV}}{ }^{\prime}=\sum_{\gamma \gamma^{\prime}}\langle\mathrm{V}| \mathrm{T}|\gamma\rangle \rho_{\gamma \gamma^{\prime}},\langle\mathrm{V}| \mathrm{T}\left|\gamma^{\prime}\right\rangle^{*} \tag{2,3}
\end{equation*}
$$

The above Eq. (2.1) is useful since it permits separation of the decay $\mathrm{V} \rightarrow \ell^{+} \ell^{-}$ from the creation process $\gamma \mathrm{N} \rightarrow \mathrm{VN}$. Once the decay is specified it provides information on the production process by use of the decay angular distribution. Assuming that $\psi \rightarrow e^{+} e^{-}, \mu^{+} \mu^{-}$proceeds through a photon, we have

$$
\begin{equation*}
\left\langle l^{+} \ell^{-}\right| M|V\rangle=e^{2} \cdot g_{V} \cdot\left(\bar{u}_{2} \gamma^{\mu} v_{1}\right) \cdot \epsilon_{\mu}(\mathrm{V}), \tag{2,4}
\end{equation*}
$$

where $g_{V}$ is the vector meson-photon coupling constant and $\epsilon$ is the vector mesorwave function. The vector meson is, of course, assumed to be on its mass shell. Once the decay mechanism is specified it is straightforward to determine

$$
\begin{equation*}
\sigma_{\mathrm{VV}},(\theta, \phi)=\sum_{\alpha}\left\langle V^{\curlyvee}\right| \mathrm{M}|\alpha\rangle\langle\alpha| \mathrm{M}|\mathrm{~V}\rangle, \tag{2,5}
\end{equation*}
$$

where $\alpha$ refers to both lepton helicities. One might ask what changes would be expected if the lepton pair were directly coupled to $\psi$. This can easily be calculated by inserting

$$
\begin{equation*}
\left\langle l^{+} l^{-}\right| \mathrm{M}|\mathrm{~V}\rangle=c_{\lambda_{\alpha}} \cdot \mathrm{D}_{\lambda_{\mathrm{V}} \lambda_{\alpha}}^{1}(\phi, \theta,-\phi) \tag{2.6}
\end{equation*}
$$

into Eq。 2.5 ) and by going through the same analysis with the result:

$$
\sigma_{V V^{\prime}}=\frac{\left|c_{1}\right|^{2}}{2}\left[\begin{array}{lll}
-\left(1+\cos ^{2} \theta\right)+2 \delta \sin ^{2} \theta & \frac{\sin 2 \theta}{\sqrt{2}} \mathrm{e}^{\mathrm{i} \phi}(1-2 \delta) & \sin ^{2} \theta \mathrm{e}^{2 \mathrm{i} \phi}(1-2 \delta)  \tag{2.7}\\
\frac{\sin 2 \theta}{\sqrt{2}} \mathrm{e}^{-\mathrm{i} \phi}(1-2 \delta) & 2 \sin ^{2} \theta+4 \delta \cos ^{2} \theta & \frac{-\sin 2 \theta}{\sqrt{2}} \mathrm{e}^{\mathrm{i} \phi}(1-2 \delta) \\
\sin ^{2} \theta \mathrm{e}^{-2 \mathrm{i} \phi}(1-2 \delta) & \frac{-\sin 2 \theta}{\sqrt{2}} \mathrm{e}^{-\mathrm{i} \phi}(1-2 \delta) & \left(1+\cos ^{2} \theta\right)+2 \delta \sin ^{2} \theta
\end{array}\right]
$$

where $\delta=\left|\frac{c_{0}}{c_{1}}\right|^{2}$. Note that $\sigma_{V V}{ }^{\text {® }}$ for the photon coupling Eq. $(2.4)$ is obtained by setting $\delta \equiv 0$, corresponding to a transverse coupling. Let us concentrate on the density matrix $\rho_{\mathrm{VV}}$, and go back to Eq。(2.3). So far we have not specified the form of the photon density matrix. It can be chosen in a particularly suitable form such that the photon polarization vector becomes explicit. This 'standard decomposition' is

$$
\begin{equation*}
\rho(\mathrm{V})=\rho^{\circ}+\sum_{\alpha=1}^{3} \mathrm{P}_{\gamma}^{\alpha} \cdot \rho^{\alpha} ; \tag{2.8}
\end{equation*}
$$

so that the corresponding decay angular distribution reads

$$
\begin{equation*}
\mathrm{W}(\theta, \phi)=\mathrm{W}^{\mathrm{o}}(\theta, \phi)+\sum_{\alpha=1}^{3} \mathrm{P}_{\gamma}^{\alpha} \cdot \mathrm{W}^{\alpha}(\theta, \phi) \tag{2,9}
\end{equation*}
$$

with the $W^{i}(\theta, \phi)$ given by ${ }^{1}$

$$
\begin{align*}
\mathrm{W}^{0}(\theta, \phi)= & \frac{1}{2}\left(1+\rho_{00}^{0}\right)+\frac{1}{2}\left(1-3 \rho_{00}^{0}\right) \cos ^{2} \theta \\
& +\sqrt{2} \operatorname{Re}^{2} \rho_{10}^{0} \sin 2 \theta \cos \phi+\rho_{1-1}^{0} \sin ^{2} \theta \cos 2 \phi  \tag{2.10}\\
\mathrm{~W}^{1}(\theta, \phi)= & \rho_{11}^{1}\left(1+\cos ^{2} \theta\right)+\rho_{00}^{1} \sin ^{2} \theta \\
& +2 \operatorname{Re}^{1} \rho_{10}^{1} \sin 2 \theta \cos \phi+\rho_{1-1}^{1} \sin ^{2} \theta \cos 2 \phi  \tag{2.11}\\
\mathrm{~W}^{2}(\theta, \phi)= & -\sqrt{2} \operatorname{Im} \rho_{10}^{2} \sin 2 \theta \sin \phi-\operatorname{Im} \rho_{1-1}^{2} \sin ^{2} \theta \sin 2 \phi  \tag{2.12}\\
\mathrm{~W}^{3}(\theta, \phi)= & -\sqrt{2} \operatorname{Im} \rho_{10}^{3} \sin 2 \theta \sin \phi-\operatorname{Im} \rho_{1-1}^{3} \sin ^{2} \theta \sin 2 \phi \tag{2.13}
\end{align*}
$$

## III. GLUON EXCHANGE MODEL

In this section we assume the $\psi$ to consist of a pair of heavy quarks (c-quarks) which interact via gluon exchange with the conventional $S U(3)$-quarks (q-quarks) of the nucleon as drawn in Fig. 2. Such a picture is natural in a quark-gluon theory of hadrons and their interactions, particularly in the case of $\psi$ photoproduction, where quarks cannot be interchanged between the $\psi$ and the nucleon. Furthermore, we assume that it is reasonable to retain only the lowest order, two gluon exchange graphs. This is particularly well-justified in the large -t region, where asymptotic freedom ${ }^{3}$ arguments suggest that the quark-gluon coupling constant may be small due to the large momentum carried by the gluons. At small $t$, lowest order perturbation theory may not be valid, as is indicated by the diffractive t-dependence of photoproduction. Nevertheless, a two gluon exchange picture may still be tenable in this region if one invokes a quark-bag interaction to provide the exponential $t$ dependence. This is the case in the Low-Nussinov model ${ }^{4}$ of the Pomeron. Therefore, we consider it worthwhile to investigate the consequences of the two gluon exchange picture for the spin dependence of $\psi$ photoproduction. Having chosen a model for the Pomeron, we now consider the nature of the $\psi$. Motivated by the success of the charmonium model ${ }^{5}$ in describing the spectrum and decays of the pions, we assume that the $\psi$ is a nonrelativistic bound state of a c-c pair. Due to the large charmed quark mass, the quarks are almost free and the $\psi^{\top}$ s momentum is equipartitioned between them. Thus our model is defined by the diagrams
shown in Fig. 3. In what follows, we perform the loop integrations, and devełop a technique to find the asymptotic form of the helicity amplitudes. We proceed in three steps: we first perform the loop integration for the case in which all particles are scalars (for clearness of presentation), subsequently the c-quarks are taken to be fermions whereas the gluons are still treated as scalars and, finally, the gluons are taken to be vectors. The nucleon is treated as a scalar throughout. The six Feynman diagrams in Fig. 3 form the smallest set of diagrams compatible with photon gauge invariance; the exchanged gluons are not gauge invariant. Since the external particles are color singlets, the calculation is performed according to the rules for QED. The infrared problem is escaped by giving the gluons a finite mass $\mathrm{m}_{\mathrm{G}}$ in the propagator denominator. The dependence of the results on the value of $m_{G}$ is discussed in detail in Section IV.

## A. All Scalars

The essential difficulty in calculating the Feynman diagrams drawn in Fig. 3 is the loop integration. It can be explicitly performed by use of Feynman parametric integrals. In Appendix A we explain the method and give details of the calculation, whereas we simply state our results here:

$$
\begin{array}{ll}
T_{j}=G \cdot \frac{2}{t-m_{\psi}^{2}} & j=(a, b, c, d) \\
L_{j} \equiv \int_{0}^{1}(d \alpha)^{4} I_{j}(\alpha), & I_{j}(\alpha) \equiv \frac{\delta(1-\Sigma \alpha)}{D_{j}^{2}} \tag{3.2}
\end{array}
$$

The index j indicates which diagram we are describing and $G$ contains all coup－ ling cönstants and i－factors appearing in the vertices and propagators，as well as factors due to the loop－integration：

$$
\begin{equation*}
\mathrm{G} \equiv(-\mathrm{ie})(-\mathrm{ig})^{4}(\mathrm{i})^{5} \frac{1}{(2 \pi)^{4}}\left(-\frac{\pi^{2}}{\mathrm{i}}\right) \tag{3.3}
\end{equation*}
$$

Similarly，the amplitudes for diagrams（e）and（f）read：

$$
\begin{array}{ll}
\mathrm{T}_{\mathrm{j}}=2 \mathrm{G} \cdot \mathrm{~L}_{\mathrm{j}}(\mathrm{~s}, \mathrm{t}) & \mathrm{j}=(\mathrm{e}, \mathrm{f}), \\
\mathrm{L}_{\mathrm{j}} \equiv \int_{0}^{1}(\mathrm{~d} \alpha)^{5} \mathrm{I}_{\mathrm{j}}(\alpha), & \mathrm{I}_{\mathrm{j}}(\alpha) \equiv \frac{\delta(1-\Sigma \alpha)}{\mathrm{D}_{\mathrm{j}}^{3}} \tag{3.5}
\end{array}
$$

$D_{j}$ contains the kinematical variables $s$ and $t$ and differs for each diagram apart from the fact that $\mathrm{L}_{\mathrm{e}, \mathrm{f}}$ involve a 5 －dimensional $\alpha$－integration．We identify

$$
\begin{align*}
& \mathrm{D}_{\mathrm{a}} \equiv \mathrm{D}_{\mathrm{s}}(4), \mathrm{D}_{\mathrm{c}} \equiv \mathrm{D}_{\mathrm{u}}(4), \mathrm{D}_{\mathrm{e}} \equiv \mathrm{D}_{\mathrm{s}}(5),  \tag{3,6}\\
& \mathrm{D}_{\mathrm{b}} \equiv \mathrm{D}_{\mathrm{u}}(4), \mathrm{D}_{\mathrm{d}} \equiv \mathrm{D}_{\mathrm{s}}(4), \mathrm{D}_{\mathrm{f}} \equiv \mathrm{D}_{\mathrm{u}}(5),
\end{align*}
$$

where $D_{s}(4)$ and $D_{u}(4)$ have been defined in Eqs．（A．10）and（A．16）；similarly， the explicit forms of $D_{S}(5)$ and $D_{u}(5)$ are given in EqS。（A。18）and（A。23）。The labels（4）and（5）refer to the loop with four and five internal lines，respective－ ly．Therefore $D(4)$ appears in the amplitudes of diagrams $j=(a, b, c, d)$ ，where－ as $D(5)$ appears in the ones with $j=(e, f)$ ．Since diagrams（ $b, d, f$ ）are obtained from diagrams（a，c，e）by the exchange $p_{1} \leftrightarrow-p_{2}$ their form is obtained by the replacement $s \leftrightarrow u$ in $T_{a}, T_{c}$ ，and $T_{e}$ ．Note that in this case of all－scalar
particles diagrams (a) and (c) are also related by $s \mapsto u$ crossing; this is no longer the case for spinning particles.

Before going over to the spinning case we discuss the analytic structure of these diagrams. Diagrams (a) and (d) possess a cut along the positive real axis of the complex s-plane whose branch point is at

$$
\begin{equation*}
\mathrm{s}_{\mathrm{B}_{1}} \equiv\left(\mathrm{~m}_{\mathrm{N}}+\mathrm{m}_{\psi}\right)^{2}=16.3 \mathrm{GeV}^{2} \tag{3,7}
\end{equation*}
$$

There is no cut on the negative real axis for these two diagrams. The amplitudes corresponding to diagrams (b) and (c) have correspondingly a cut on the positive real axis in the complex u-plane, which, in the complex s-plane, gives a cut along the negative axis with its branch point at

$$
\begin{equation*}
s_{B_{2}} \equiv\left(m_{N}^{2}-2 m_{N} m_{\psi}^{-t}\right)=-t-4.937 \mathrm{GeV}^{2} \tag{3.8}
\end{equation*}
$$

A similar analysis shows that diagrams (e) and (f) possess the same cuts with the same branch points. The amplitude $\mathrm{T}_{\mathrm{e}}$ therefore has two cuts, the conventional s-cut on the positive real axis as well as the u-cut on the negative real axis. $T_{e}$ can be split up into a sum of two terms, each contributing to only the right- or only the left-hand cut. The same applies for diagram (f)。

## B. Scalar Gluons

In the preceding subsection we have set up the formalism for spinless particles and now go a step further by taking the quark-spin into account; the gluons are still treated as scalars. The amplitudes of the first three diagrams in Fig. 3 may be cast into the form

$$
\begin{align*}
& \mathrm{T}_{\mathrm{a}}=\mathrm{G} \cdot \frac{2}{\mathrm{t}-\mathrm{m}_{\psi}^{2}}\left[\overline{\mathrm{u}}_{2}\left(\epsilon \circ \mathrm{k}^{\mathrm{t}}-\not \subset \mathrm{k}\right) \not \psi_{\mathrm{a}} \mathrm{v}_{1}\right],  \tag{3,9}\\
& \mathrm{T}_{\mathrm{c}}=\mathrm{G} \cdot \frac{2}{\mathrm{t}-\mathrm{m}_{\psi}^{2}}\left[\overline{\mathrm{u}}_{2} \not{ }_{\mathrm{c}}\left(\mathbb{k} \notin-\epsilon \circ \mathrm{k}^{\mathrm{q}}\right) \mathrm{v}_{1}\right], \tag{3.10}
\end{align*}
$$

$$
\begin{equation*}
\mathrm{T}_{\mathrm{e}}=2 \mathrm{G} \cdot \overline{\mathrm{u}}_{2} \not \mathrm{~K}_{\mathrm{e}} \mathrm{v}_{1} \tag{3,11}
\end{equation*}
$$

and the corresponding ones for diagrams（b，d，f）are obtained by the replacement $\mathrm{p}_{1} \rightarrow-\mathrm{p}_{2}$ 。 The $\not_{\mathrm{j}}$ represent the loop integrals with an internal fermion line and are evaluated in Appendix A．They have the form

$$
\begin{equation*}
Z_{\mathrm{j}}=\int_{0}^{1}(\mathrm{~d} \alpha)^{4} \cdot \mathscr{D}_{\mathrm{j}} \cdot \mathrm{I}_{\mathrm{j}}(\alpha) \quad \mathrm{j}=(\mathrm{a}, \mathrm{~b}, \mathrm{c}, \mathrm{~d}), \tag{3.12}
\end{equation*}
$$

and their spin factors are defined by

$$
\begin{align*}
& \Phi_{\mathrm{a}} \equiv\left\{\mathrm{~m}_{\mathrm{c}}-\not x_{1}\right\}, \quad \Phi_{\mathrm{c}} \equiv\left\{\mathrm{~m}_{\mathrm{c}}+\not \not{x}_{2}\right\}, \\
& \Phi_{\mathrm{b}} \equiv\left\{\mathrm{~m}_{\mathrm{c}}-\not x_{2}\right\}, \quad \Phi_{\mathrm{d}} \equiv\left\{\mathrm{~m}_{\mathrm{c}}+\not x_{1}\right\}, \tag{3.13}
\end{align*}
$$

where $x_{1}$ and $x_{2}$ are defined in Eqs．（A．30）and（A。31）．The loop term for dia－ grams（e）and（f）is a 5－dimensional integral of the form given in Eq．（3．12）（ $\mathrm{j}=$ $e, f)$ with the spin factors

$$
\begin{align*}
& S_{\mathrm{e}} \equiv \notin \frac{\mathrm{D}_{\mathrm{s}}}{2}+\left\{\mathrm{m}_{\mathrm{c}}+y_{1}\right\} \notin\left\{\mathrm{m}_{\mathrm{c}}+y_{1}-\mathrm{k}\right\} \\
& S_{\mathrm{f}} \equiv \notin \frac{\mathrm{D}}{2}+\left\{\mathrm{m}_{\mathrm{c}}-\not 夕_{2}\right\} \notin\left\{\mathrm{m}_{\mathrm{c}}+y_{2}-\not k\right\}, \tag{3.14}
\end{align*}
$$

where $y_{1}$ and $y_{2}$ are defined in Eqs．（A．34）and（A．35）．We are now in a position to write the sum of all diagrams with four internal lines in a compact form：

$$
\begin{equation*}
T_{a}+T_{b}+T_{c}+T_{d}=G \cdot \frac{2}{t-m_{\psi}^{2}} \int_{0}^{1}(d \alpha)^{4}\left\{\sum_{j=a}^{d} M_{j}(p, \alpha) \cdot I_{j}(\alpha)\right\} \tag{3.15}
\end{equation*}
$$

$M_{j}(p, \alpha)$ contains all spin factors of diagram $j$ ，such as，for example，

$$
\begin{equation*}
\left.\mathrm{M}_{\mathrm{a}}(p, \alpha) \equiv \overline{\mathrm{u}}_{2}\left[\epsilon \circ \mathrm{k}^{\prime}-\notin k\right) \delta_{a}\right] \mathrm{v}_{1}, \tag{3.16}
\end{equation*}
$$

and similarly for all other diagrams $j=(a, b, c, d)$ ．The $M_{j}(p, \alpha)$ are functions of the invariant kinematical variables $s, t$ and（masses）${ }^{2}$ and depend linearly on the integration parameters $\alpha$ ．Insertion of the explicit forms of $\$_{j}$ into Eq。（3．12）
shows that it can be cast into the invariant expansion

$$
\begin{equation*}
T_{a b c d} \equiv T_{a}+T_{b}+T_{c}+T_{d}=G \cdot \frac{2}{t-\mathrm{m}_{\psi}^{2}} \sum_{i=1}^{4} Q_{i} \circ\left[W_{i}(\mathrm{~s})+W_{i}(\mathrm{u})\right] \tag{3.17}
\end{equation*}
$$

$Q_{i}$ contains all the spin factors, whereas $W_{i}$ is a sum of $\alpha$-parameter integrals。 We have defined

$$
\begin{align*}
& \left.\mathrm{Q}_{1} \equiv \overline{\mathrm{u}}_{2}\left[\epsilon \cdot \mathrm{k}^{\prime}-\notin \mathrm{k}\right) \dot{p}_{1}-\dot{p}_{1}\left(\mathrm{k} \notin-\epsilon^{\circ} \mathrm{k}^{\prime}\right)\right] \mathrm{v}_{1} \\
& Q_{2} \equiv-\bar{u}_{2}\left[\left(\epsilon \circ \mathrm{k}^{\imath}-\phi k\right) \dot{p}_{2}-\not \phi_{2}\left(k \notin-\epsilon \circ \mathrm{k}^{\mathrm{l}}\right)\right] \mathrm{v}_{1}  \tag{3,18}\\
& Q_{3} \equiv-\bar{u}_{2}\left[\left(\epsilon \cdot \mathrm{k}^{8}-\notin k\right) \frac{k^{\prime}}{2}-\frac{k^{\prime}}{2}\left(k \notin-\epsilon \cdot \mathrm{k}^{\prime}\right)\right] \mathrm{v}_{1} \\
& \left.Q_{4} \equiv \bar{u}_{2}\left[\left(\epsilon \circ \mathrm{k}^{8}-\not \subset k\right)+0 k \notin-\epsilon \circ \mathrm{k}^{\prime}\right)\right] \mathrm{v}_{1} .
\end{align*}
$$

We have calculated the matrix elements for the possible helicity combinations and list our results in Appendix B. It is straightforward to determine the $\mathrm{W}_{\mathrm{i}}{ }^{\text {is }}$, with the result

$$
\begin{align*}
& \mathrm{W}_{1 \ldots 4}(\mathrm{~s})=\int_{0}^{1}(\mathrm{~d} \alpha)^{4}\left[\alpha_{2} / \alpha_{2}+\alpha_{3} / \alpha_{2}+\alpha_{3}+\alpha_{4} / 1\right] \cdot \mathrm{I}_{\mathrm{S}}(\alpha),  \tag{3.19}\\
& \mathrm{W}_{1 \ldots 4}(\mathrm{u})=\int_{0}^{1}(\mathrm{~d} \alpha)^{4}\left[\alpha_{2}+\alpha_{3} / \alpha_{2} / \alpha_{2}+\alpha_{3}+\alpha_{4} / 1\right] \cdot \mathrm{I}_{\mathrm{u}}(\alpha), \tag{3.20}
\end{align*}
$$

where the first argument in the bracket of the integrand corresponds to $W_{1}$, the second one to $\mathrm{W}_{2}$, and so on.

We can perform the same steps for diagrams (e+f)。Writing

$$
\begin{equation*}
y_{1}^{\prime} \equiv k^{\prime} \cdot a_{1}+\not k^{\prime} \cdot a_{2}+\not p_{1} \cdot a_{3} \tag{3.21}
\end{equation*}
$$

with the $a_{i}$ determined by Eq. (A. 34), the spin factors in Eqs. (3.14) are expanded and lead to the invariant expansion:

$$
\begin{equation*}
T_{e f} \equiv T_{e}+T_{f}=2 G \cdot \sum_{i=5}^{13} Q_{i}\left[W_{i}(s)+W_{i}(u)\right] \tag{3.22}
\end{equation*}
$$

The "spin amplitudes" $Q_{i}$ have been chosen as follows:

$$
\begin{align*}
& Q_{5} \vec{\equiv} \bar{u}_{2}\left[k^{\prime} \notin k^{\prime}\right] v_{1} \quad, \quad Q_{9} \equiv \bar{u}_{2}\left[k \notin p_{1}+p_{1} \notin k\right] \mathrm{v}_{1}, \\
& Q_{6} \equiv \bar{u}_{2}\left[p_{1} \notin b_{1}\right] \mathrm{v}_{1} \quad, \quad \mathrm{Q}_{10} \equiv-\overline{\mathrm{u}}_{2}\left[k^{\prime} k k\right] \mathrm{v}_{1} \quad, \\
& Q_{7} \equiv \bar{u}_{2}\left[k^{\prime} \notin k+k \notin k^{\prime}\right] \mathrm{v}_{1} \quad, \quad Q_{11} \equiv-\bar{u}_{2}\left[p_{1} \notin k\right] \mathrm{v}_{1} \quad, \\
& Q_{8} \equiv \bar{u}_{2}\left[k^{\prime} \notin p_{1}+\not b_{1} \notin k^{\prime}\right] \mathrm{v}_{1}, \quad \mathrm{Q}_{12} \equiv-\overline{\mathrm{u}}_{2}[\notin k] \mathrm{v}_{1} \mathrm{~m}_{\mathrm{c}} \quad, \\
& \mathrm{Q}_{13} \equiv \bar{u}_{2}[\notin] \mathrm{v}_{1}, \tag{3.23}
\end{align*}
$$

and their forms, evaluated for different spin combinations, are given in Appendix $\mathrm{B}_{0}$ The invariant amplitudes read

$$
\begin{gather*}
W_{5-13}(s)=\int_{0}^{1}(d \alpha)^{5}[\ldots]^{\circ} I_{s}(\alpha) \\
{[\ldots] \equiv\left[a_{1}^{2} / a_{3}^{2} / a_{1} a_{2} / a_{1} a_{3} / a_{2} a_{3} / a_{1} / a_{3} / 1 /\left(m_{c}^{2}-D_{s} / 2\right)\right]} \tag{3,24}
\end{gather*}
$$

where again the first argument corresponds to $W_{5}$, the second to $W_{6}$, and so on. The last argument $\left(\mathrm{m}_{\mathrm{c}}^{2}-\mathrm{D}_{\mathrm{s}} / 2\right)$ corresponds to $\mathrm{W}_{13}$. The corresponding amplitudes for the $u$-channel coming from diagram (f), $W_{i}(u)$, are defined as in Eq. (3.24) with the $\mathrm{a}_{\mathrm{i}}$ (defined by Eq. (3.21)) determined by $\forall_{2}$ in Eq。(A.35), with $D_{S}$ replaced by $D_{u^{\circ}}$

Up to this point our presentation has not involved any approximations and the $\alpha$-parameter integrals $W_{i}$ could in principle be determined exactly. Since our investigation is mostly concerned with the behavior at large energies, we have chosen to introduce their high energy approximation. By applying the techniques of $\epsilon$-integration or Mellin transformation we find the asymptotic forms for the invariant amplitudes $W_{i}$ in $T_{a b c d}$

$$
\begin{align*}
& \mathrm{W}_{1}(\mathrm{~s})+\mathrm{W}_{1}(\mathrm{u}) \Longrightarrow \frac{\mathrm{s} \rightarrow \infty}{\Longrightarrow} \frac{\mathrm{i} \pi}{\mathrm{~s}} \mathrm{f}_{1}+\frac{2}{\mathrm{~s}} \mathrm{f}_{2}, \\
& \mathrm{~W}_{2}(\mathrm{~s})+\mathrm{W}_{2}(\mathrm{u}) \Longrightarrow \frac{\mathrm{i} \pi}{\mathrm{~s}} \mathrm{f}_{1}-\frac{2}{\mathrm{~s}} \mathrm{f}_{2},  \tag{3.25}\\
& \mathrm{~W}_{3}(\mathrm{~s})+\mathrm{W}_{3}(\mathrm{u}) \Longrightarrow 2 \frac{\mathrm{i} \pi}{\mathrm{~s}} \mathrm{f}_{1}, \\
& \mathrm{~W}_{4}(\mathrm{~s})+\mathrm{W}_{4}(\mathrm{u}) \Longrightarrow 2 \frac{\mathrm{i} \pi}{\mathrm{~s}} \mathrm{f}_{1},
\end{align*}
$$

$f_{1}$ and $f_{2}$ are slowly varying $t$-dependent functions whose detailed forms are found in Eqs. (3.51-3.52) 。

In the above formalism we have not yet taken into account the fact that we intend to describe photoproduction of a spin-1 particle. The amplitudes in Eqs. (3.17-3.22) describe production of a pair of c-quarks where both are assumed to have equal 4-momentum (since binding effects are ignored in this approach). Due to parity relations between the amplitudes with different helicities, we may restrict ourselves to the photon helicity: $\lambda_{\gamma}=+1$ throughout. We define the helicity amplitudes for $\mathrm{c} \overline{\mathrm{c}}$-production as $\mathrm{T}_{\mathrm{c}}\left(\lambda_{\mathrm{c}} \lambda_{\mathrm{c}} ; \lambda_{\gamma}\right)$ and similarly for $\psi$-photoproduction $\mathrm{T}\left(\lambda_{\psi}, \lambda_{\gamma}\right)$. Then

$$
\begin{align*}
& \mathrm{T}(1,1)=\mathrm{T}_{\mathrm{c}}\left(\frac{1}{2} \frac{1}{2} ; 1\right) \\
& \mathrm{T}(0,1)=\frac{1}{\sqrt{2}}\left[\mathrm{~T}_{\mathrm{c}}\left(\frac{1}{2}-\frac{1}{2} ; 1\right)+\mathrm{T}_{\mathrm{c}}\left(-\frac{1}{2}+\frac{1}{2} ; 1\right)\right]  \tag{3.26}\\
& \mathrm{T}(-1,1)=\mathrm{T}_{\mathrm{c}}\left(-\frac{1}{2}-\frac{1}{2} ; 1\right)
\end{align*}
$$

We are now able to give the asymptotic form of the amplitude $\mathrm{T}_{\text {abcd }}$ for $\psi$ photoproduction which receives contributions from diagrams with four propagators in the loop only

$$
\begin{equation*}
\mathrm{T}(1,1) \stackrel{\mathrm{S} \rightarrow \infty}{\Longrightarrow} \sqrt{2} \cdot 8 \cdot \mathrm{G} \frac{1}{\mathrm{t}-\mathrm{m}_{\psi}^{2}} \cdot \mathrm{f}_{2} \tag{3.27}
\end{equation*}
$$

$$
\begin{align*}
& T(0,1) \stackrel{\mathrm{S} \rightarrow \infty}{\Longrightarrow} \frac{\mathrm{G} \sqrt{-t}}{\mathrm{t}-\mathrm{m}_{\psi}^{2}}\left[\frac{\mathrm{i} \pi}{\mathrm{~s}} \mathrm{f}\left\{\frac{\mathrm{t}}{2 \mathrm{~m}_{\mathrm{c}}}+5 \mathrm{~m}_{\mathrm{c}}+\frac{\mathrm{m}_{\mathrm{N}}^{2}}{2 \mathrm{~m}_{\mathrm{c}}}\right\}-\frac{2}{\mathrm{~s}} \mathrm{f}_{2}\left\{-\frac{\mathrm{t}}{2 \mathrm{~m}_{\mathrm{c}}}+5 \mathrm{~m}_{\mathrm{c}}+\frac{\mathrm{m}_{\mathrm{N}}^{2}}{2 m_{\mathrm{c}}}\right\}\right]  \tag{3.28}\\
& \mathrm{T}(-1,1) \Longrightarrow \frac{4 \sqrt{2} \mathrm{G} \cdot \mathrm{t}}{\mathrm{t}-\mathrm{m}_{\psi}^{2}} \cdot \frac{\mathrm{i} \pi}{\mathrm{~s}} \cdot \mathrm{f}_{1} . \tag{3.29}
\end{align*}
$$

We carry out the same kind of analysis for diagrams (e) and (f). By use of the REDUCE computer program we determined the asymptotic s-dependence of the $\mathrm{T}_{\mathrm{ef}}$-amplitudes; since integrals with an $\alpha_{3}$ in the integrand depend asymptotically only on $|s|$ we find:

$$
\begin{align*}
& T(1,1)<\frac{s \rightarrow \infty}{<}, \\
& T(0,1) \sim \frac{1}{s}, \\
& T(-1,1) \sim \frac{1}{s}, \tag{3.30}
\end{align*}
$$

$\mathrm{W}_{8}, \mathrm{~W}_{9}$, and $\mathrm{W}_{11}$ all contain a multiplicative $\alpha_{3}$; they are of nonleading order in s (see subsection D), and we neglect their contributions. However, we find that for $T(0,1)$ and $T(-1,1)$, the contributions involving $Q_{5}, Q_{7}$, and $Q_{13}$ also behave like $1 / \mathrm{s}$ asymptotically. Specifically, the leading asymptotic contribution to $T(0,1)$ and $T(-1,1)$ is given by

$$
\begin{gather*}
\mathrm{T}_{\mathrm{ef}} \stackrel{\mathrm{~s} \rightarrow \infty}{\Longrightarrow 2 \mathrm{G}\left[\mathrm{Q}_{5}\left\{\mathrm{~W}_{5}(\mathrm{~s})+\mathrm{W}_{5}(\mathrm{u})\right\}+\mathrm{Q}_{7}\left(\left\{\mathrm{~W}_{7}(\mathrm{~s})+\mathrm{W}_{7}(\mathrm{u})\right\}+\frac{1}{2}\left\{\mathrm{~W}_{10}(\mathrm{~s})+\mathrm{W}_{10}(\mathrm{u})\right\}\right.\right.} \\
\left.\left.-\frac{1}{4}\left\{\mathrm{~W}_{12}(\mathrm{~s})+\mathrm{W}_{12}(\mathrm{u})\right\}\right)+\mathrm{Q}_{13} \cdot\left\{\mathrm{~W}_{13}(\mathrm{~s})+\mathrm{W}_{13}(\mathrm{u})\right\}\right] \tag{3.31}
\end{gather*}
$$

Taking the $Q_{i}$ and the $W_{i}$ to leading order in $s$ we find

$$
\begin{align*}
& T(0,1) \stackrel{s \rightarrow \infty}{\Longrightarrow} G \cdot \frac{i \pi}{s} \sqrt{\frac{-t}{m_{c}^{2}}}\left[m_{c}^{2}\left\{2 h_{t}\left(\alpha_{2}^{2}\right)-2 h_{t}\left(\alpha_{2} \alpha_{4}\right)+3 h_{t}(1)\right\}-\widetilde{h}_{t}(1)\right]  \tag{3.32}\\
& T(-1,1) \Longrightarrow G \cdot \frac{i \pi}{s} t \sqrt{2}\left[h_{t}\left(\alpha_{2}^{2}\right)-h_{t}\left(\alpha_{2} \alpha_{4}\right)+\frac{h_{t}(1)}{2}\right] \tag{3033}
\end{align*}
$$

where the $t$－dependent functions $h_{t}$ are defined in $(3.58)$ ．Therefore，these con－ tributions must be added to the contributions from $\mathrm{T}_{\text {abcd }}$ to obtain $\mathrm{T}(0,1)$ and $T(-1,1)$ in leading order．We note that the $T(1,1)$ amplitude decreases asymp－ totically at least one power in s faster than $\mathrm{T}_{\text {abcd }}$ ，although the $\mathrm{T}(0,1)$ and $T(-1,1)$ amplitudes contribute to order $1 / \mathrm{s}$ and so compete with $\mathrm{T}_{\mathrm{abcd}}{ }^{\circ}$

C．Spin－1 Gluons
We now extend our formalism to the case of spin－1 gluons（and spin－$\frac{1}{2} \mathrm{c}$－ quarks）．However，before going into the details，we first assert gauge invari－ ance．We cut diagrams $(a+c+e)$ at the gluon lines and consider only the $c$－quark part．The sum of these diagrams does satisfy the divergence condition $\mathrm{k} \cdot\left(\mathrm{T}_{\mathrm{a}}+\mathrm{T}_{\mathrm{c}}+\mathrm{T}_{\mathrm{e}}\right)=0$ due to the Ward－Takahashi identity。 ${ }^{6}$ An explicit proof for the model under consideration may be constructed without difficulty．

The calculation of the amplitudes here requires investigation of the spin fac－ tors $\not \psi_{j}\left(\right.$ or $\left.\$_{j}\right)$ 。 Evaluation of their structure for diagram（a）gives（see Appen－ dix A）
where the $\not \phi_{i}$ are linear combinations of the external momenta as defined in Eqs． （ $A_{0} 39$ ）。The expansion coefficients（ $a_{i}, b_{i}, c_{i}$ ）are linear functions of the integra－ tion variables and are specified in Eqs．（A．40）．Since the amplitude for diagram （b）is obtained by the exchange $p_{1} \leftrightarrow-p_{2}$ ，which can be absorbed in the $v_{i}$ by re－ defining their coefficients $a_{i}$ ，we have：$\delta_{b} \equiv \Phi_{a}\left(v_{i}\right)$ ．The $v_{i}$ are fixed as in Eq。 （A．39），but the functions $a_{i}$ are replaced by the definitions in Eq。（A．44）。

The amplitudes of diagrams（c）and（a）are connected by the exchange： $p_{1} \rightarrow-p_{2}, m_{c} \rightarrow-m_{c}$ and an overall minus sign in the amplitude leading to： $\mathbb{S}_{c}$ $\equiv-\Phi_{\mathrm{a}}\left(\mathrm{w}_{\mathrm{i}}\right)$ ．The above modification is absorbed not in the $\mathrm{a}_{\mathrm{i}}$ but in the newly de－ fined variable $W_{i}$ as given in Eq。（A．43）。The functions $a_{i}$ are the same as for
diagram（a）and are defined in Eq。（A。40）。 Diagram（d）is calculated analo－ gously， $\mathscr{X}_{d} \equiv \$_{c}\left(w_{i}\right)$ ，with the $W_{i}$ defined in Eq。（A。43）and its coefficients $a_{i}$ given by Eq。（A。44）．

The spin factors of diagrams（e）and（f）are composed of three contributions：

$$
\begin{equation*}
\mathscr{S}_{\mathrm{e}} \equiv \mathscr{D}_{\mathrm{e}_{1}}+\phi_{\mathrm{e}_{2}}+\phi_{\mathrm{e}_{3}} \tag{3.35}
\end{equation*}
$$

$$
\begin{aligned}
& \phi_{\mathrm{e}_{1}} \equiv \notin \cdot\left[3 \mathrm{D}_{\mathrm{s}}^{2}-\frac{\mathrm{D}_{\mathrm{s}}}{2} \mathrm{~m}_{\mathrm{c}}^{2}\right]+\mathrm{D}_{\mathrm{s}}\left[\left(\mathrm{v}_{2} \cdot \epsilon\right) \dot{\psi}_{4}+\left(\mathrm{v}_{3} \cdot \epsilon\right) \dot{k}_{1}\right]-\frac{\mathrm{D}_{\mathrm{s}}}{2}\left[\dot{\phi}_{3} \notin \dot{\phi}_{2}-\mathrm{m}_{\mathrm{c}}\left(\phi_{1} \notin+\notin \phi_{4}\right)\right] \\
& +\left[\left(\mathrm{m}_{\mathrm{c}}^{2}-\frac{\mathrm{D}_{\mathrm{s}}}{2}\right) \dot{y}_{1} \notin \dot{y}_{4}+\mathrm{D}_{\mathrm{s}}\left\{\dot{x}_{1} \dot{x}_{2} \notin+d \dot{x}_{3} \dot{X}_{4}\right\}\right],
\end{aligned}
$$

$$
\begin{align*}
& \Phi_{\mathrm{e}_{3}}=\not \forall_{1}^{\not \phi_{2}}{ }^{\notin \dot{\phi}}{ }_{3}^{\not \phi_{4}}, \tag{3.36}
\end{align*}
$$

where $\not{ }_{i}$ is a linear combination of the external momenta as defined in Eq．（A．47）。 The spin factor of diagram（f），$\$_{f} \equiv \$_{e}\left(v_{i}\right)$ ，differs only in the functions $a_{i} \ldots$ in $v_{i}$（apart from the replacement $D_{S} \rightarrow D_{u}$ ），which are given in Eq。（ $A_{。} 49$ ）for dia－ gram（e）and in Eq。（A．50）for diagram（f）．

In principle it is now possible to write an invariant expansion for each dia－ gram as was done in Eqs．（3．17）and（3．22）．However，in practice this is an endless undertaking．We therefore have chosen to determine the leading order approximation of the helicity amplitudes and could easily extend this analysis to any higher orders．By symbolic computing we have determined the first two terms of the spin factors dominating for asymptotic s－values．We write

$$
\begin{equation*}
T_{j}=G \cdot \frac{2}{t-m_{\psi}^{2}} \int_{0}^{1}(d \alpha)^{4} M_{j}(p, \alpha) I_{j}(\alpha) \quad j=(a, b, c, d), \tag{3.37}
\end{equation*}
$$

where

$$
\begin{equation*}
M_{a}(p, \alpha) \equiv \bar{u}_{2}\left[\left(\epsilon \cdot k^{\prime}-\notin k\right) \delta_{a}\right] v_{1}, \tag{3.38}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{M}_{\mathrm{c}}(\mathrm{p}, \alpha) \equiv \overline{\mathrm{u}}_{2}\left[\$_{\mathrm{c}}\left(k_{\dot{\prime}}-\epsilon \circ \mathrm{k}^{\prime}\right)\right] \mathrm{v}_{1} \tag{3.39}
\end{equation*}
$$

The same definitions hold for $\mathrm{M}_{\mathrm{b}}\left(\mathrm{M}_{\mathrm{d}}\right)$ which differ from $\mathrm{M}_{\mathrm{a}}\left(\mathrm{M}_{\mathrm{c}}\right)$ only in the expansion coefficients of the $\mathrm{v}_{\mathrm{i}}\left(\mathrm{w}_{\mathrm{i}}\right)$ apart from changing $\mathrm{D}_{\mathrm{S}}$ into $\mathrm{D}_{\mathbf{u}}$ 。 The analogous form applies for diagrams (e) and (f)

$$
\begin{equation*}
T_{j}=2 \cdot G \cdot \int_{0}^{1}(d x)^{5} M_{j}(p, \alpha) I_{j}(\alpha), \tag{3.40}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{m}_{\mathrm{e}}(\mathrm{p}, \alpha) \equiv \bar{u}_{2}\left(\phi_{\mathrm{e}_{1}}+\phi_{\mathrm{e}_{2}}+\mathrm{S}_{\mathrm{e}_{3}}\right) \mathrm{v}_{1} \equiv \mathrm{M}_{\mathrm{e}_{1}}+\mathrm{M}_{\mathrm{e}_{2}}+\mathrm{M}_{\mathrm{e}_{3}} \tag{3,41}
\end{equation*}
$$

The leading order contributions of the matrix elements $M_{j}(p, \alpha)$ have been evaluated by a symbolic computing program for the spin combinations

$$
\begin{equation*}
\lambda_{\gamma}=+1, \quad \lambda_{\mathrm{c}}= \pm \frac{1}{2}, \quad \lambda_{\overline{\mathrm{c}}}= \pm \frac{1}{2} \tag{3,42}
\end{equation*}
$$

All amplitudes $M_{j}(p, \alpha)(j=a, b, c, d)$ may then be expressed in the form:

$$
\begin{align*}
& M_{j}(++)=s \cdot\left(\xi_{1} \ldots \xi_{5}\right), \\
& M_{j}(-+)=\sqrt{\frac{-t}{m_{c}^{2}}} \cdot s \cdot\left(\eta_{1} \ldots \eta_{5}\right), \\
& M_{j}(--)=\quad t \cdot\left(\zeta_{1} \ldots \zeta_{5}\right), \tag{3.43}
\end{align*}
$$

where

$$
\begin{equation*}
\left(\xi_{1} \circ \cdot \xi_{5}\right) \equiv s \cdot \xi_{1}+t^{\circ} \xi_{2}+m_{c}^{2} \cdot \xi_{3}+m_{N}^{2} \cdot \xi_{4}+D \cdot \xi_{5} \tag{3.44}
\end{equation*}
$$

The expansion coefficients $\xi, \eta, \zeta$ are linear combinations of products of the integration variables $\alpha$ and $\mathrm{D} \equiv \mathrm{D}(\alpha)$ is familiar from the 'all-scalar case ${ }^{\gamma}$ and reduces the power in the denominators of $\mathrm{I}(\alpha)$. Our notation is as follows: $M_{a}( \pm, \pm)$ is the matrix element Eq。 $(3.43)$ of diagram (a). The helicity of the c-quark (wave function $\overline{\mathrm{u}}_{2}$ ) is indicated in the first argument, whereas the second argument refers to the helicity of the $\bar{c}$-quark (wave function $v_{1}$ ). We do
not consider it useful to write down all functions $(\xi, \eta, \zeta)$ (which differ for each diagram and each spin combination) but list in Appendix C those which are important for later arguments.

In the same way we have evaluated the asymptotic forms of the amplitude $M_{e}$ as given in Eq. (3.41) and found:

$$
\begin{align*}
& M_{e_{1}}{ }^{(++)}=\quad\left\{m_{c}^{2} \circ\left(\xi_{1} \ldots \xi_{4}\right)-D_{s}\left(\xi_{5} \ldots \xi_{8}\right)\right\}, \\
& M_{e_{1}}(-+)=\sqrt{\frac{-t}{m_{c}^{2}}}\left\{m_{c}^{2}\left(\eta_{1} \ldots \eta_{4}\right)-D_{s}\left(\eta_{5} \ldots \eta_{8}\right)\right\}, \\
& M_{e_{1}}(--)=\left\{m_{c}^{2} \zeta_{1} \quad-D_{s} \zeta_{2}\right\} \quad \text {, }  \tag{3.45}\\
& M_{e_{2}}(++)=\quad s \cdot\left(\xi_{1} \ldots \xi_{4}\right), \\
& M_{e_{2}}(-+)=\sqrt{\frac{-t}{m_{c}^{2}}} m_{c}^{2} \cdot\left(\eta_{1} \ldots \eta_{4}\right), \\
& M_{e_{2}}(--)=\quad t \cdot\left(\zeta_{1} \ldots \zeta_{4}\right) \text {, }  \tag{3.46}\\
& M_{e_{3}}{ }^{(++)}=\quad s \circ\left(\xi_{1} \ldots \xi_{4}\right), \\
& \mathrm{M}_{\mathrm{e}_{3}}(-+)=\sqrt{\frac{-\mathrm{t}}{\mathrm{~m}_{\mathrm{c}}^{2}}} \mathrm{~s} \cdot\left(\eta_{1} \ldots \eta_{4}\right), \\
& M_{e_{3}}(--)=\quad t \circ\left(\zeta_{1} \circ \circ \zeta_{4}\right) \text {, } \tag{3,47}
\end{align*}
$$

where

$$
\begin{equation*}
\left(\xi_{1} \cdot \cdots \cdot \xi_{4}\right)=\mathrm{s} \cdot \xi_{1}+\mathrm{t} \cdot \xi_{2}+\mathrm{m}_{\mathrm{c}}^{2} \cdot \xi_{3}+\mathrm{m}_{\mathrm{N}}^{2} \xi_{4} \tag{3.48}
\end{equation*}
$$

The functions $\xi_{i}, \eta_{i}, \ldots$, etc., are linear combinations of products formed by the integration parameters and differ for each diagram and contribution. For ease of notation we have dropped the index referring to the diagram or specific
contribution．Each should therefore carry this index，as，for instance，$\xi_{i} \equiv$ $\dot{\xi}_{i}\left(\mathrm{e}_{1} ; \vec{\alpha}\right)$ or $\eta_{i} \equiv \eta_{i}(\mathrm{a} ; \alpha)$ ，and so on。Some of the functions $\xi_{i}, \eta_{i}$ ，and $\zeta_{i}$ are listed in Appendix C．The same results hold for diagram（f），which，however， has different functions（ $\xi, \eta, \xi$ ）。

Before discussing further approximations we would like to stress that the amplitudes $M_{a} \ldots M_{f}$ given in Eqs．（3．43）and（3．45）－（3．47）are leading order approximations in the spin factors for asymptotic s－values．The invariant amp－ litudes have so far been treated exactly leading to integrals of the form

$$
\begin{equation*}
J(\xi) \equiv \int_{0}^{1}(\mathrm{~d} \alpha)^{\mathrm{n}} \cdot \xi(\alpha) \cdot \mathrm{I}(\alpha) \quad(\mathrm{n}=4,5) \tag{3.49}
\end{equation*}
$$

whose asymptotic form will be considered in the following step．

## D．Asymptotic Form of Feynman Parameter Integrals

The integrals $J(\xi)$ can in principle be calculated exactly．However we have chosen to determine their leading asymptotic behavior．Mellin transform tech－ niques can be used in order to determine the first，second，．．．correction terms．${ }^{7}$ One might question whether such an approximation is justified at ener－ gies just above the threshold rise．In order to gain some insight we have cal－ culated for some integrals their asymptotically leading contribution as well as their first correction terms and find in all cases that for $\mathrm{s} \gtrsim 30 \mathrm{GeV}^{2}$ a leading order approximation gives the correct order of magnitude of the integrals al－ though the correction terms are not yet entirely negligible．

In what follows，we present the asymptotic behavior of the integrals arising in the case of scalar gluon exchange．The evaluation of diagrams（a－d）requires
 $\mathrm{W}_{1 \ldots \ldots 4}(\mathrm{u})$ in Eq。（3．20），which are easily found by use of $\epsilon$－integration tech－ niques．${ }^{8}$ The result is

$$
\underset{\mathrm{J}(\xi)}{\rightarrow} \xrightarrow[\mathrm{s} \rightarrow \infty]{ }\left\{\begin{array}{l}
\frac{\ln \left(-\frac{\mathrm{s}}{2}\right)}{\left(+\frac{\mathrm{s}}{2}\right)} \cdot \mathrm{f}_{\mathrm{t}}(\xi) \text { for } \xi \equiv\left\{1, \alpha_{2}, \alpha_{4}\right\}  \tag{3.50}\\
\frac{1}{\left(+\frac{s}{2}\right)} \\
\mathrm{f}_{\mathrm{t}}(\xi) \text { for } \xi \equiv\left\{\alpha_{3}\right\},
\end{array}\right.
$$

where the $t$-dependent functions $f_{t}(\xi)$ are

$$
\begin{equation*}
f_{1} \equiv f_{t}(1)=2 f_{t}\left(\alpha_{2}\right)=2 f_{t}\left(\alpha_{4}\right)=\int_{0}^{1}(d \alpha)^{2} \frac{\delta(1-\Sigma \alpha)}{\left[d_{s}^{0}\right]}=-\frac{2}{t \cdot \delta} \ln \left|\frac{1-\delta}{1+\delta}\right|^{2} \tag{3.51}
\end{equation*}
$$

with

$$
\begin{gather*}
\delta \equiv \sqrt{1-\frac{4 \mathrm{~m}_{\mathrm{G}}^{2}}{\mathrm{t}}} \\
\mathrm{f}_{2} \equiv \mathrm{f}_{\mathrm{t}}\left(\alpha_{3}\right)=\int_{0}^{1}(\mathrm{~d} \alpha)^{3} \frac{\delta(1-\Sigma \alpha)}{\left[\mathrm{d}_{\mathrm{s}}^{1}\right]}=\int_{0}^{1} \mathrm{dy} \frac{1}{\delta} \ln \frac{\delta+\mathrm{t}(1-\mathrm{y})}{\delta-\mathrm{t}(1-\mathrm{y})} \tag{3,52}
\end{gather*}
$$

with

$$
\delta \equiv\left[t^{2}(1-\mathrm{y})^{2}-4 t\left\{\mathrm{ym}_{\mathrm{N}}^{2}+(1-\mathrm{y}) \mathrm{m}_{\mathrm{G}}^{2}\right\}\right]^{\frac{1}{2}}
$$

The integrals arising in the invariant amplitudes of diagrams (e) and (f) are $W_{5 \ldots 13}(\mathrm{~s})$ and $W_{5 \ldots 13}{ }^{(\mathrm{u})}$ as defined in Eqs。(3.24)。 Insertion of the explicit form for $D_{j}(5)$ from EqS. ( $A, 18$ ) and ( $A, 23$ ) shows that these integrals have two cuts; one is along the positive real axis and the other is along the negative real axis. By use of the following transformation we were able to separate the two pinching singularities in the integrand and to reexpress the resulting integrals as a sum of two terms where each contains only one cut. The transformation is

$$
\begin{align*}
& \bar{\alpha}_{5}=\alpha_{5}-\alpha_{1}, \quad\left|\frac{\partial\left(\alpha_{1}, \alpha_{5}\right)}{\partial\left(\alpha_{1}, \alpha_{5}\right)}\right|=\frac{1}{2} .  \tag{3.53}\\
& \bar{\alpha}_{1}=\alpha_{5}+\alpha_{1},
\end{align*}
$$

Note that the integration range is limited to the shaded region in Fig．4。 Ac－ cordingly the integrals arising in Eq。（3．24）can be written as

$$
\begin{equation*}
J(\xi)=\frac{1}{2} \int(\mathrm{~d} \bar{\alpha})^{5}\left[\left(\ldots \bar{\alpha}_{5 \ldots)}\right)+\left(\ldots-\bar{\alpha}_{5} \ldots\right)\right], \tag{3.54}
\end{equation*}
$$

where $\left(\ldots, \alpha_{5} \ldots\right)$ is a shorthand notation for the integrand after introducing the above transformation and the convention of writing

$$
\begin{equation*}
\int(\mathrm{d} \bar{\alpha})^{5} \equiv \int_{0}^{1} \mathrm{~d} \bar{\alpha}_{1} \ldots \mathrm{~d} \alpha_{4} \int_{-\bar{\alpha}_{1}}^{+\bar{\alpha}_{1}} \mathrm{~d} \bar{\alpha}_{5} \tag{3.55}
\end{equation*}
$$

is introduced．Each of the contributions in Eq。（3．54）has only one cut．The asymptotic behavior can therefore be determined by use of Mellin transforma－ tion．Straightforward application of this method to integrals with

$$
\begin{equation*}
\xi=\left\{1,\left(\alpha_{2}-\alpha_{4}\right), \alpha_{4}\left(\alpha_{2}-\alpha_{4}\right),\left(\alpha_{2}-\alpha_{4}\right)^{2}\right\} \tag{3.56}
\end{equation*}
$$

gives

$$
\begin{equation*}
J(\xi) \stackrel{s \rightarrow \infty}{\Longrightarrow}-\frac{i \pi}{2 s} h_{t}(\xi) \tag{3.57}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{h}_{\mathrm{t}}(\xi) \equiv \int_{0}^{1}(\mathrm{~d} \bar{\alpha})^{3} \xi \frac{\delta(1-\Sigma \alpha)}{\left[\mathrm{d}_{\mathrm{s}}^{\mathrm{o}}\right]^{2}} \tag{3.58}
\end{equation*}
$$

All other contributions with $\xi=\alpha 3$－（．．．0）were found to contribute asymptoti－ cally at least one power less in S ．

We find it useful to make a few comparative remarks about the functions $f_{t}(\xi)$ and $h_{t}(\xi)$ concerning their size，$t$－dependence，and $m_{G}$－dependence，which will be of use for our discussion in Section $V$ ．
（i）In order to illustrate the size and t－dependence of the functions $f_{t}\left(h_{t}\right)$ we give in Fig。 5 （Fig。6）their t －dependence with the masses fixed at $\mathrm{m}_{\mathrm{V}}=$ 3．1 GeV and $m_{G}=1.0 \mathrm{GeV}$ ．One notices that the size of $f_{t}$ and $h_{t}$
diminishes if more integration parameters $\alpha$ appear in $\xi$ and that the t－ dependence is flat．
（ii）In Fig。 7 we show variation of these integrals with decreasing gluon mass． $f_{t}(1)$ and $h_{t}(1)$ both increase rapidly due to the infrared singularity。
（iii）There is no $\mathrm{m}_{\mathrm{V}}$－dependence in the integrals $\mathrm{f}_{\mathrm{t}}(\xi)$ whereas the integrals $h_{t}(\xi)$ decrease with increasing vector meson mass since the factor $1 /\left(t-m_{V}^{2}\right)$ is hidden；this becomes apparent in the limit $\mathrm{m}_{\mathrm{G}} \rightarrow 0$（Fig。8）。

The integrals $J(\xi)$ appearing in the case of spin－1 gluons for diagrams（a－d）are of similar structure to those discussed above in Eq．（3．50）．Integrals with no $\alpha_{1}$ or $\alpha_{3}$ follow the asymptotic behavior of Eq．$(3.50)$ whereas integrals with $\alpha_{1}^{\mathrm{n}}$ 。（\％）or $\alpha_{3}^{\mathrm{n}}$ 。（．．．）behave asymptotically simi larly to Eq．（3．50）with modified functions $f_{t}(\xi)$ and $h_{t}(\xi)$ ，of course．Integrals with $\alpha_{1} \cdot \alpha_{3}$ in the inte－ grand do not appear．The size，mass－and t－dependence of these integrals is similar to the ones discussed above．However in this case of spin－1 gluon ex－ change there appear new integrals of the form

$$
\begin{equation*}
\widetilde{J}(1) \equiv \int_{0}^{1}(\mathrm{~d} \alpha)^{4} \frac{\delta(1-\Sigma \alpha)}{\left[\mathrm{D}_{\mathrm{s}}\right]} \stackrel{\mathrm{s} \rightarrow \infty}{\Longrightarrow} \frac{\ln ^{2}\left(-\frac{\mathrm{s}}{2}\right)}{\mathrm{s}} . \tag{3.59}
\end{equation*}
$$

The D in the denominator appears with one power less here，which is due to the multiplicative $D$ in the expansion（3．44）。 If the $\epsilon$－integration method is used in order to determine the asymptotic form，it is advantageous to use Spence func－ tions and their asymptotic behavior．For those who prefer to apply the Mellin transformation we mention that the singularity in the integrand arises in the factor $\left(\frac{1}{A^{3+\beta}}\right)$ ．Similarly one can show that

$$
\begin{equation*}
\widetilde{\mathrm{J}}\left(\alpha_{3}\right) \stackrel{\mathrm{s} \rightarrow \infty}{\Longrightarrow} \frac{\ln \left(-\frac{\mathrm{s}}{2}\right)}{\left(\frac{\mathrm{S}}{2}\right)} . \tag{3.60}
\end{equation*}
$$

## IV．FEATURES OF THE SPIN ANALYSIS

In this section，we continue our detailed analysis of the set of Feynman dia－ grams shown in Fig．3，and present results of a numerical study of the helicity amplitudes and density matrix elements．Some numerical results for the density matrix have been given in Ref． 2 and have been compared with the predictions of a variety of models；here we wish to analyze the two gluon exchange picture in more detail，with emphasis on the gluon and vector meson mass dependence of the amplitudes．We first comment on the amplitudes describing vector gluon exchange between spin－$\frac{1}{2}$ quarks and a spinless nucleon．The spin part of the amplitudes $T_{a} \ldots T_{f}$ is contained in the $M_{j}(p, \alpha)$ ．Their structure is the same for all diagrams（a－d）as given in Eqs。（3．43），and in Eqs．（3．45）－ （3．47）for diagrams（e）and（f）．The difference for each diagram arises only through the $\alpha$－dependent functions（ $\xi_{i}, \eta_{\mathrm{i}}, \zeta_{\mathrm{i}}$ ）。

We consider first the loop diagrams with 4 internal lines，$j=(a, b, c, d)$ 。In principle we should give the explicit forms of all functions $\xi(\alpha)_{\ldots} \ldots$ Due to lim－ itation of space we list those which are relevant for our discussion in Appendix C．The fact that $D_{a}=D_{d}$ and $D_{b}=D_{c}$ leads us to consider the sums（ $M_{a}+M_{d}$ ） and（ $M_{b}+M_{c}$ ）in order to spot cancellations．Let us examine the details：
1．A superficial look at Eqs．$(3,43)$ might lead one to the incorrect conclusion that some of the amplitudes grow like $\mathrm{s}^{2}$ ．Integration over the $\alpha$－param－ eters introduces at least a factor $1 / \mathrm{s}$ 。 Since there are no cancellations the amplitudes $M_{j}(++)$ indeed grow like $s^{1}$（if $\ell n s$ terms are ignored）．In the sum $\mathrm{T}_{\mathrm{abcd}}$ ，the real part $\propto \ln s$ vanishes in leading order，and the dom－ inant contribution is purely imaginary。

2．The leading contributions to $\mathrm{M}_{\mathrm{j}}(-+)$ cancel in the sums since

$$
\begin{equation*}
\eta_{1}(\mathrm{a})=-\eta_{1}(\mathrm{~d}), \quad \eta_{1}(\mathrm{~b})=-\eta_{1}(\mathrm{c}) \tag{4.1}
\end{equation*}
$$

as a quick look at Appendix C shows。 Therefore

$$
\begin{equation*}
\mathrm{M}(-+) \stackrel{\mathrm{S} \rightarrow \infty}{\Longrightarrow} \mathrm{~s}^{\mathrm{o}} . \tag{4.2}
\end{equation*}
$$

3．In $M_{j}(--)$ ，the $\zeta_{1}$－terms do not entirely cancel so that $M(--)$ is asymptoti－ cally of the same order in $s$ as $M(-+)$ ；however，numerical calculations show that for asymptotic s－values $M(--) \ll M(-+)$ because of the size of the $t-$ dependent functions $\mathrm{f}_{\mathrm{t}}(\xi)$ 。
4． $\mathrm{M}_{\mathrm{j}}(++)$ contains a term $\xi_{5} \equiv\left\{8-3 \alpha_{3}\right\}$ which is multiplied by D．The re－ sulting integral behaves asymptotically as

$$
\begin{equation*}
J\left(\xi_{5}\right) \equiv \int_{0}^{1}(\mathrm{~d} \alpha)^{4}\left(8-3 \alpha_{3}\right) \frac{\delta(1-\Sigma \alpha)^{\mathrm{S}} \rightarrow \infty}{\mathrm{D}_{\mathrm{S}}} \stackrel{\left[\ln \left(-\frac{\mathrm{S}}{2}\right)\right]^{2}}{\left(-\frac{\mathrm{S}}{2}\right)} \cdot \mathrm{f}_{\mathrm{t}} \tag{4.3}
\end{equation*}
$$

and substantially enhances $M_{j}(++)$ due to the $\ell n^{2} s$－term。 Similar terms in $M(-+)$ and $M(--)$ are much less influential。

5．We point to the explicit $m_{c}$ dependence in $M_{j}(-+)$ which tends to suppress this amplitude for increasing values of $m_{c}$ ．There is further $m_{c}$－depen－ dence hidden in the expansion coefficients $\xi_{1} \ldots$ which，however，is present in all amplitudes and is of less importance for the spin characteristics．We will elaborate more on these questions in the numerical discussions．

We now consider the amplitudes containing the loop over five internal lines．For computational convenience we have split the amplitudes into three parts：

$$
\begin{align*}
& M_{e}(p, \alpha) \equiv M_{e_{1}}+M_{e_{2}}+M_{e_{3}} \\
& M_{f}(p, \alpha) \equiv M_{f_{1}}+M_{f_{2}}+M_{f_{3}} \tag{4.4}
\end{align*}
$$

and now discuss their properties．In Appendix $C$ we give the explicit forms of the relevant functions $\xi_{i}, \eta_{i}, \zeta_{i}$ ．Inspection of Eqs。（3．45）－（3．47）leads us to the following conclusions：

1．The contributions due to $\xi_{1}$ in（ $\mathrm{T}_{\mathrm{e}_{1}}+\mathrm{T}_{\mathrm{f}_{1}}$ ）do not cancel due to the $\alpha_{5}$－inte－ gration and $\xi_{1}\left(e_{1}\right)=-\xi_{1}\left(f_{1}\right)$ ．There is a nonvanishing contribution due to $\eta_{1}$ 。

2． $\mathrm{M}_{\mathrm{e}_{1}}{ }^{(++)}$（and $\mathrm{M}_{\mathrm{e}_{1}(--) \text { ）possess a multiplicative } \mathrm{m}_{\mathrm{c}}^{2} \text {－dependence and thus }}$ grow for increasing quark masses，whereas $M_{e_{1}}(-+)$ is less affected。
3．The dominant contribution to diagrams（e）and（f）comes from（ $\mathrm{T}_{\mathrm{e}_{2}}+\mathrm{T}_{\mathrm{f}_{2}}$ ） since $\xi_{1}\left(e_{2}\right)=\xi_{1}\left(f_{2}\right)$ and the asymptotic behaviors of the Feynman param－ eter integrals $J(\xi)$ for diagrams（e）and（f）are identical．Again，the dom－ inant contribution is purely imaginary，but has opposite phase to the dom－ inant contribution from $T_{\text {abcd }}$
4．One notices that $\mathrm{M}_{\mathrm{e}_{2}}{ }^{(++)}$has no explicit $\mathrm{m}_{c^{-d e p e n d e n c e ; ~ w e ~ h a v e ~ n u m e r i-~}}$－ cally verified that the integrals $J(\xi)$ show a strong decrease as $m_{c}^{2}$ in－ creases．Therefore，to leading order diagrams（e）and（f）decrease as $m_{c}^{2}$ grows．
5．The contribution（ $\mathrm{T}_{\mathrm{e}_{3}}+\mathrm{T}_{\mathrm{f}_{3}}$ ）seemingly leads to an $\mathrm{s}^{2}$－type increase．How－ ever $\xi_{1}$ is proportional to $\alpha_{3}$ which leads，as we show in Appendix C，to a decrease $J\left(\xi_{1}\right) \sim 1 / s^{2}$ ；in addition there are cancellations．
6．$M_{e_{3}}{ }^{(-+)}$seemingly rises like $s^{1}$ in the asymptotic region．However $\eta_{1}\left(e_{3}\right)$ ， given in Appendix $C$ ，shows that most contributions are proportional to $\alpha_{3}$ ， which leads to the integral $J\left(\alpha_{3}\right) \sim 1 / s^{2}$ ．The remaining term $A_{0}$ depends on（ $\alpha_{2}-\alpha_{4}$ ）．One can show that asymptotically the integrals over $\alpha_{2}$ and over $\alpha_{4}$ cancel since $d_{s}^{o}$ is symmetrical under the exchange of $\alpha_{2}$ and $\alpha_{4}$ ． The same applies for the integral with $\alpha_{2}{ }^{\circ} \alpha_{5}$ as part of the integrand。We conclude that $\mathrm{M}_{\mathrm{e}_{3}}(-+) \stackrel{\mathrm{S} \rightarrow \infty}{\Longrightarrow} \mathrm{s}^{\mathrm{o}}$.
Our second comment concerns the $m_{G}$－dependence of the density matrix element $\rho_{00}^{0}$ for vector gluon exchange。 In our analysis we noticed that the amplitudes depend substantially on the gluon mass，which leads us to further investigate the $\mathrm{m}_{\mathrm{G}}$－dependence of $\rho_{00^{\circ}}^{0}$ Taking $\mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ ，we show this dependence for $\rho$ and $\psi$ photoproduction in Fig．9．The same results are plotted at $t=-2.0(\mathrm{GeV} / \mathrm{c})^{2}$
in Fig．10。 In each case there is a sharp bump in $\rho_{00}^{0}$ at a particular gluon mass－The position and height of the bump change when $m_{V}$ and／or $t$ are varied。 At low $t$ ，the peaks for $\rho$ and $\psi$ are of about the same height，as is the case for $\mathrm{m}_{\mathrm{V}}$ lying between the $\rho$ and $\psi$ mass．At $\mathrm{t}=-2.0(\mathrm{GeV} / \mathrm{c})^{2}$ the $\rho$ peak is much higher than the $\psi$ peak．At small $t$ ，as $m_{V}$ is decreased，the bump occurs at smaller values of $m_{G^{\circ}}$ This is illustrated in Fig。11，where the position of the peak is plotted in the $\mathrm{m}_{\mathrm{G}} \mathrm{m}_{\mathrm{V}}$ plane for $\mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ 。

To reveal the origin of this dramatic behavior，we plot in Fig。 12 the amp－ litudes $\mathrm{T}(1,1)$ and $\mathrm{T}(0,1)$ versus $\mathrm{m}_{\mathrm{G}}$ for $\psi$ photoproduction at $\mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ ． This shows that $\operatorname{Im} T(1,1)$ has a zero at $m_{G}=0.55 \mathrm{GcV}$ ．Therefore，$|T(1,1)|$ is reduced at this point and $\rho_{00}^{0} \approx|\mathrm{~T}(0,1)|^{2} /|\mathrm{T}(1,1)|^{2}$ is enhanced．The van－ ishing of $\operatorname{Im} T(1,1)$ is due to a cancellation between $\operatorname{Im} T(1,1)$ of diagrams（ $a-d$ ） and $\operatorname{Im} T(1,1)$ of diagrams $(\theta+f)$ ，which are plotted in Fig．13。．Since $\operatorname{Im} T(1,1)$ ef $\approx-\operatorname{Im} \mathrm{T}(1,1)_{\text {abcd }}$ ，the resulting nonflip amplitude $|\operatorname{Im} \mathrm{T}(1,1)|$ is much smaller than either of its component amplitudes．

To analyze this phenomenon further，we note that for both $T(1,1)$ abcd and $T(1,1)_{\text {ef }}$ terms involving the invariant integrals $f_{t}(1)$ and $h_{t}(1)$ dominate（see Figs．5，6）；of course other terms contribute as well，but they are smaller． Therefore，we examine the behavior of the functions $f_{t}(1)$ and $h_{t}(1)$ ．In Fig． 7 we exhibit the $m_{G}$－dependence of $f_{t}(1)$ and $h_{t}(1)$ for $t=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ 。 This be－ havior is mirrored in the nonflip amplitudes（Fig。13）and the general result that $T(1,1)_{\text {ef }} \approx-T(1,1)_{\text {abcd }}$ is a consequence of the sign and magnitude of these integrals．The detailed pattern of cancellation in $\operatorname{Im} T(1,1)$ is governed by these terms，and also，to a lesser extent，by the other terms in the invariant expansion of the amplitude．

When the gluon mass is of the same order of magnitude as the other vari－ ables s，$t, m_{V}^{2}, m_{N}^{2}$ in the problem（i．$e_{\circ}, m_{G} \rightarrow 1 \mathrm{GeV}$ ）the behavior of $f_{t}(1)$ and $h_{t}(1)$ is complicated。 In the limit $m_{G} \rightarrow 0, f_{t}$ and $h_{t} \propto \ln \left(m_{G}^{2}\right)$ as might be guessed from Fig．7，

$$
\begin{align*}
& \mathrm{f}_{\mathrm{t}} \quad \mathrm{~m}_{\underset{\mathrm{G}}{ } \rightarrow 0}^{\approx} \frac{2}{-\mathrm{t}} \ln \left(\mathrm{~m}_{\mathrm{G}}^{2}\right)+(\text { finite terms })  \tag{4.5}\\
& \mathrm{h}_{\mathrm{t}} \quad \mathrm{~m}_{\mathrm{G}} \rightarrow 0 \\
& \approx \frac{2}{-\mathrm{t}} \frac{1}{\left(\frac{t}{4}-\mathrm{m}_{\mathrm{c}}^{2}\right)} \ln \left(\mathrm{m}_{\mathrm{G}}^{2}\right)+(\text { finite terms }) . \tag{4.6}
\end{align*}
$$

It is easy to show that the contributions of these terms to the nonflip amplitude cancel（apart from the finite terms）in the limit $\mathrm{m}_{\mathrm{G}} \rightarrow 0$ ，so that there is no $\ln \left(\mathrm{m}_{\mathrm{G}}^{2}\right)$－type divergence in the overall amplitude。

In Figs． 9 and 10 we saw that the position of the bump in $\rho_{00}^{0}$ depends on t 。 This suggests that，for certain values of $\mathrm{m}_{\mathrm{G}}$ ，the t －dependence of $\rho_{00}^{0}$ might ex－ hibit unexpected behavior．As an example of such behavior we show in Fig． 14 the t－dependence of $\rho_{00}^{0}$ for $\rho$－photoproduction at $m_{G}=0.045 \mathrm{GeV}$ ．Note that this value of $m_{G}$ is in the region of the peak at $t=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$（Fig。9）。Fig。 14 shows that the expected peak is quite narrow in $t$ ，and represents a signifi－ cant deviation from the general behavior of $\rho_{00^{\circ}}^{0}$ ．Again，the position of the peak depends on $\mathrm{m}_{\mathrm{G}}$ ，so that the t －dependence of $\rho_{00}^{0}$ could，in principle，be used to determine $\mathrm{m}_{\mathrm{G}}$ ．

As the vector meson mass increases，peaks in the t－dependence of $\rho_{00}^{0}$ be－ come broader．In Fig． 15 we show $\rho_{00}^{0}$ for $\psi$ photoproduction with $\mathrm{m}_{\mathrm{G}}=1 \mathrm{GeV}$ ． There is a broad enhancement centered at $\mathrm{t}=-2.0(\mathrm{GeV} / \mathrm{c})^{2}$ ，after which $\rho_{00}^{0}$ resumes its usual monotonic t－dependence．Again，this effect is rather sen－ sitive to the value of $\mathrm{m}_{\mathrm{G}}$ ，so that the results presented in Figs． 14 and 15 should be regarded as illustrative of the kind of behavior that can be expected in this model．

We conclude this section with some comments on the results described above. Since $\psi$ photoproduction is not an elastic process, the indefinite sign of Im $\mathrm{T}(1,1)$ does not necessarily imply a violation of unitarity. Note, however, that gluon gauge invariance is violated due to the use of a nonzero gluon mass. Since gauge invariance and unitarity are intimately connected it may be that violation of gluon gauge invariance manifests itself by flipping the sign of $\operatorname{Im} T(1,1)$ when $m_{G}$ becomes of the order of the other masses in the problem. We resorted to a study of the massive case because of the difficulty of carrying out calculations in the infrared limit.

The main result of our analysis, which appears to hold for all values of the gluon mass, is that helicity conservation is almost perfectly satisfied for $\psi$ photoproduction even near threshold. For $\rho$ photoproduction, the results of the model defined in Fig. 3 probably require more modification due to the more relativistic nature of the bound state. Furthermore, quark interchange diagrams can also contribute in this case. For these reasons we have not presented any comparison of our results for $\rho$ photoproduction with the data. On the other hand, the data ${ }^{9}$ are consistent with SCHC violation of $10 \%$ or less, in agreement with our qualitative results.

## V．CONCLUSION

By combining the two－vector－gluon exchange model of the Pomeron with the nonrelativistic bound state picture for the $\psi$ ，we have obtained a simple，cal－ culable model for $\psi$ photoproduction．It corresponds to the simplest set of QCD diagrams consistent with photon gauge invariance．We have proceeded on the assumption that this model should provide a reasonably accurate description of the spin dependence of $\psi$ photoproduction，and have investigated its consequences in considerable detail．

Asymptotically，this picture provides SCHC，as do all acceptable models of photoproduction．It therefore becomes necessary to study the model in the threshold region in order to distinguish its predictions from those of other mod－ els．Unfortunately，the necessity of evaluating a loop integral precludes the pos－ sibility of obtaining analytic results in this region．However，by expanding the amplitudes in powers of $s$ ，we have obtained results for the density matrix ele－ ments which we expect to be reliable fairly near threshold．Much of the paper is devoted to a detailed discussion of the techniques we have applied to the calcu－ lation of the amplitudes．

The main conclusion to be drawn from our analysis is that two vector gluon exchange conserves helicity to a very good approximation even near threshold。 The amount of SCHC violation depends quite sensitively on the gluon effective mass，although it is never greater than $10 \%$ in $\rho_{00}^{0}$ for $\psi$ photoproduction。Other models which satisfy SCHC asymptotically predict a measurable helicity flip near threshold，${ }^{2}$ in contrast to the two vector gluon exchange model．When data on the spin dependence of $\psi$ photoproduction become available，it will be possible to test the predictions of the various models，and in particular to confirm or rule out the simple QCD picture studied here。

## ACKNOWLEDGEMENTS

We would like to thank Hannu Miettinen, Fred Gilman, and Stan Brodsky for clarifying discussions. One of us (B. H.) thanks the Swiss National Science Foundation for financial support, and the other (A.C.D.W.) acknowledges support from the National Research Council of Canada in the form of an NRC Fellowship. Both of us wish to acknowledge the warm hospitality of Professor S . D. Drell and SLAC.

## APPENDIX A

This appendix gives details of the loop integration discussed in Section III. For clarity of presentation we first treat the Feynman diagrams in Fig。 4 for the case of all-scalar particles. Subsequently we generalize to spin- $\frac{1}{2} \mathrm{c}$-quarks (keeping the gluon spin 0 ) and finally we consider the case of spin- $\frac{1}{2} \mathrm{c}$-quarks interacting via spin-1 gluons with the spinless nucleon. We first list a few integrals which will be of later use:

$$
\begin{align*}
& I_{0} \equiv \int_{-\infty}^{\infty} \frac{d^{4} \ell}{\left[A \pm \ell^{2}\right]^{\lambda}}=\frac{i^{2}}{(\lambda-1)(\lambda-2)} \frac{1}{A^{\lambda-2}},  \tag{A,1}\\
& I_{1}^{\mu} \equiv \int_{-\infty}^{+\infty} \ell^{\mu} \frac{d^{4} \ell}{\left[A \pm \ell^{2}\right]^{\lambda}}=0,  \tag{A.2}\\
& I_{2}^{\mu \nu} \equiv \int_{-\infty}^{+\infty}{ }_{l}^{\mu} \ell^{\nu} \cdot \frac{d^{4} \ell}{\left[A \pm l^{2}\right]^{\lambda}}=I_{0}\left\{\frac{ \pm g^{\mu \nu} \cdot A}{2(\lambda-3)}\right\},  \tag{A.3}\\
& I_{4} \equiv \int_{-\infty}^{+\infty} \ell^{4} \frac{d^{4} \ell}{\left[A \pm \ell^{2}\right]^{\lambda}}=I_{0}\left\{\frac{6 A^{2}}{(\lambda-3)(\lambda-4)}\right\} . \tag{A.4}
\end{align*}
$$

We begin with the case of all-scalar particles. The amplitude for diagram (a) then reads

$$
\begin{gather*}
T_{a}=G \cdot \frac{1}{\left(k-\frac{k^{i}}{2}\right)^{2}-m_{c}^{2}} \cdot L_{a},  \tag{A.5}\\
L_{a} \equiv\left(-\frac{i}{\pi^{2}}\right) \cdot \int_{-\infty}^{+\infty} d^{4} \ell\left\{\prod_{r=1}^{4} \frac{1}{q_{r}^{2}-m_{r}^{2}}\right\}, \tag{A,6}
\end{gather*}
$$

where the internal momenta are defined as in Fig. 4a. In order to perform the loop integration we use the Feynman parameter integral

$$
\begin{equation*}
\frac{1}{\mathrm{f}_{1} \cdot \mathrm{f}_{\mathrm{N}}}=(\mathrm{N}-1)!\int_{0}^{\mathrm{I}}(\mathrm{~d} \alpha)^{\mathrm{N}} \frac{\delta(1-\Sigma \alpha)}{\left[\sum_{1}^{\mathrm{N}} \alpha_{\mathrm{r}} \cdot \mathrm{f}_{\mathrm{r}}\right]^{\mathrm{N}}} \tag{A.7}
\end{equation*}
$$

which permits evaluation of the loop integration by writing

$$
\begin{equation*}
\psi(\alpha, \ell) \equiv \sum_{\mathrm{r}=1}^{4} \alpha_{\mathrm{r}} \circ\left(\mathrm{q}_{\mathrm{r}}^{2}-\mathrm{m}_{\mathrm{r}}^{2}\right) \equiv \mathrm{A}^{\circ}(\ell-\mathrm{B} / \mathrm{A})^{2}+\left(\frac{\mathrm{AC}-\mathrm{B}^{2}}{\mathrm{~A}}\right) \tag{A.8}
\end{equation*}
$$

Application of the transformation $\ell^{\prime}=\ell-B / A$ and use of Eq。 $\left(A_{0} 7\right)$ leads to the result

$$
\begin{equation*}
\mathrm{L}_{\mathrm{a}}=\int_{0}^{1}(\mathrm{~d} \alpha)^{4} \cdot \frac{\delta(1-\Sigma \alpha)}{\left[\mathrm{D}_{\mathrm{s}}\right]^{2}} . \tag{A。9}
\end{equation*}
$$

Replacement of all（momenta）${ }^{2}$－factors by the external masses and kinematical variables gives

$$
\mathrm{D}_{\mathrm{s}} \equiv \mathrm{AC}-\mathrm{B}^{2}=\frac{\mathrm{s}}{2} \alpha_{1}{ }^{\circ} \alpha_{3}+\mathrm{d}_{\mathrm{s}}
$$

where the negative definite function

$$
\begin{equation*}
d_{s}=t \cdot \alpha_{2}\left(\frac{1}{2} \alpha_{1}+\alpha_{4}\right)-m_{N^{\circ}}^{2} \alpha_{3}^{\circ}\left(\frac{1}{2} \alpha_{1}+\alpha_{3}\right)-m_{c^{\circ}}^{2} \alpha_{1}\left(\alpha_{1}+2 \alpha_{2}+2 \alpha_{3}\right)-m_{G^{\circ}}^{2}\left(\alpha_{2}+\alpha_{4}\right) \stackrel{4}{\left(\Sigma \alpha_{r}\right)} \tag{A.11}
\end{equation*}
$$

For later use we define

$$
\begin{equation*}
\mathrm{d}_{\mathrm{s}}^{1} \equiv \mathrm{~d}_{\mathrm{s}}\left(\alpha_{1}=0\right), \mathrm{d}_{\mathrm{s}}^{3} \equiv \mathrm{~d}_{\mathrm{s}}\left(\alpha_{3}=0\right), \mathrm{d}_{\mathrm{s}}^{0} \equiv \mathrm{~d}_{\mathrm{s}}\left(\alpha_{1}=\alpha_{3}=0\right) \tag{A.12}
\end{equation*}
$$

At this point we also mention the relation

$$
\begin{equation*}
\left(\mathrm{k}-\mathrm{k}^{\prime}\right)^{2}-\mathrm{m}_{\mathrm{c}}^{2}=\frac{1}{2}\left(\mathrm{t}-\mathrm{m}_{\psi}^{2}\right), \tag{A。13}
\end{equation*}
$$

which when inserted in Eq。（A．5）indicates a $t$－pole at $t=m_{\psi^{\circ}}^{2}$ We have assumed $\mathrm{m}_{\psi}^{2}=4 \mathrm{~m}_{\mathrm{c}}^{2}$ throughout．Diagram（c）could be calculated in the same way。How－ ever，we skip this step by noticing that diagram（c）is obtained from diagram（a） by the replacement $p_{1} \mapsto-p_{2}$ ．Thus

$$
\begin{equation*}
\mathrm{T}_{\mathrm{c}}=\mathrm{G} \cdot \frac{2}{\mathrm{t}-\mathrm{m}_{\psi}^{2}} \cdot \mathrm{~L}_{\mathrm{c}} \tag{A.14}
\end{equation*}
$$

with

$$
\begin{equation*}
\mathrm{L}_{\mathrm{c}}=\int_{0}^{1}(\mathrm{~d} \alpha)^{4} \frac{\delta(1-\Sigma \alpha)}{\mathrm{D}_{\mathrm{u}}^{2}} \tag{A.15}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{D}_{\mathrm{u}} \equiv-\frac{\mathrm{s}}{2} \alpha_{1} \alpha_{3}+\mathrm{d}_{\mathrm{u}} \tag{A.16}
\end{equation*}
$$

and

$$
\begin{align*}
\mathrm{d}_{\mathrm{u}}=\mathrm{t} \cdot & \left\{\alpha_{2}\left(\frac{1}{2} \alpha_{1}+\alpha_{4}\right)-\frac{1}{2} \alpha_{1} \alpha_{3}\right\}+\mathrm{m}_{\mathrm{N}}^{2} \alpha_{3}\left(\frac{1}{2} \alpha_{1}-\alpha_{3}\right) \\
& -\mathrm{m}_{\mathrm{c}}^{2} \alpha_{1}\left(\alpha_{1}+2 \alpha_{2}\right)-\mathrm{m}_{\mathrm{G}}^{2}\left(\alpha_{2}+\alpha_{4}\right)\left(\begin{array}{l}
4 \\
\sum \\
1
\end{array} \alpha_{\mathrm{r}}\right) \tag{A.17}
\end{align*}
$$

Note that $d_{u}^{1}, d_{u}^{3}, d_{u}^{o}$ ，which are defined analogously to Eqs．（A。12）for the $s$－ channel，are identical with $d_{s}^{1}, d_{s}^{3}, d_{s^{\circ}}^{0}$ All quantities $D_{s}, D_{u}, d_{s}, d_{u}$ ，etc．， should actually carry the index（4），$D_{S}=D_{S}(4) \ldots$ ，since they refer to dia－ grams $j=(a, b, c, d)$ with four internal lines．We have omitted this index in order to simplify our notation．Going through the same procedure with the amplitude for diagram（e）is straightforward and leads to

$$
\begin{equation*}
\mathrm{D}_{\mathrm{s}} \equiv \frac{\mathrm{~s}}{2} \alpha_{3}\left(\alpha_{5}-\alpha_{1}\right)+\mathrm{d}_{\mathrm{s}} \tag{A。18}
\end{equation*}
$$

where

$$
\begin{align*}
d_{s} \equiv & \frac{t}{2} h_{1}-m_{N}^{2} h_{2}-m_{c}^{2} h_{3}-m_{G}^{2} h_{4}  \tag{A。19}\\
& h_{1}=\alpha_{2}\left(\alpha_{4}+\alpha_{5}\right)+\alpha_{4}\left(\alpha_{1}+\alpha_{2}\right)-\alpha_{1} \alpha_{3} \\
h_{2} & =\alpha_{3}\left\{\alpha_{3}-\frac{1}{2}\left(\alpha_{1}-\alpha_{5}\right)\right\} \\
h_{3} & =\alpha_{1}\left(\alpha_{1}+2 \alpha_{4}+2 \alpha_{5}\right)+\alpha_{5}\left(\alpha_{5}+2 \alpha_{2}+2 \alpha_{3}\right) \\
h_{4} & =\left(\alpha_{2}+\alpha_{4}\right)\left(\begin{array}{c}
5 \\
\Sigma \\
1
\end{array} \alpha_{r}\right)
\end{align*}
$$

For later convenience we introduce the transformation

$$
\begin{equation*}
\bar{\alpha}_{1}=\alpha_{1}+\alpha_{5}, \quad \bar{\alpha}_{5}=\alpha_{5}-\alpha_{1} \tag{A.21}
\end{equation*}
$$

and newly define:

$$
\begin{equation*}
\bar{D}_{\mathrm{S}}=\frac{\mathrm{s}}{2} \alpha_{3} \bar{\alpha}_{5}+\bar{d}_{\mathrm{S}} \tag{A.22}
\end{equation*}
$$

$\overline{\mathrm{d}}_{\mathrm{s}}$ is defined by $\mathrm{d}_{\mathrm{S}}$ with $\alpha_{1}$ and $\alpha_{5}$ replaced according to the above transformation. Furthermore we will need the quantities $\bar{d}_{S}^{1}, \bar{d}_{S}^{5}, \bar{d}_{S}^{0}$ which are specified as in Eq. (A.12). Similarly we introduce

$$
\begin{equation*}
\mathrm{D}_{\mathrm{u}} \equiv-\frac{\mathrm{s}}{2} \alpha_{3}\left(\alpha_{5}-\alpha_{1}\right)+\mathrm{d}_{\mathrm{u}} \tag{A.23}
\end{equation*}
$$

with

$$
\begin{align*}
& d_{\mathbf{u}} \equiv \frac{\mathrm{t}}{2} \mathrm{~h}_{1}-\mathrm{m}_{\mathrm{N}}^{2} \mathrm{~h}_{2}-\mathrm{m}_{\mathrm{c}}^{2} \mathrm{~h}_{3}-\mathrm{m}_{\mathrm{G}}^{2} \mathrm{~h}_{4}  \tag{A.24}\\
& \mathrm{~h}_{1}=\alpha_{2}\left(\alpha_{4}+\alpha_{5}\right)+\alpha_{4}\left(\alpha_{1}+\alpha_{2}\right)-\alpha_{1} \alpha_{3} \\
& \mathrm{~h}_{2}=\alpha_{3}\left\{\alpha_{3}+\frac{1}{2}\left(\alpha_{1}-\alpha_{5}\right)\right\} \\
& \mathrm{h}_{3}=\alpha_{1}\left(\alpha_{1}+2 \alpha_{3}+2 \alpha_{4}\right)+\alpha_{5}\left(\alpha_{5}+2 \alpha_{1}+2 \alpha_{2}\right) \\
& \mathrm{h}_{4}=\left(\alpha_{2}+\alpha_{4}\right)\left(\sum_{1}^{5} \alpha_{\mathrm{r}}\right) \tag{A.25}
\end{align*}
$$

Note that, again, all quantities $D_{S} \ldots$ should actually carry the index (5): $D_{S}(5)$, ..., since they refer to the diagrams with five internal lines. We have omitted this index for simplicity of notation.

We now evaluate the loop integrals $\hbar_{j}$ for spin- $\frac{1}{2} c$-quarks and spinless gluons; their form is

$$
\begin{equation*}
\not \Psi_{a} \equiv\left(-\frac{i}{\pi^{2}}\right) \int_{-\infty}^{+\infty} d^{4} \ell\left\{-\not q^{\prime}+m_{c}\right\}\left(\prod_{r=1}^{4} \frac{1}{q_{r}^{2}-m_{r}^{2}}\right) \tag{A.26}
\end{equation*}
$$

$$
\begin{align*}
& \rightarrow \quad \not K_{c} \equiv\left(-\frac{i}{\pi^{2}}\right) \int_{-\infty}^{+\infty} d^{4} \ell\left\{\ell+m_{c}\right\}\left(\begin{array}{c}
4 \\
r=1 \\
q_{r}^{2}-m_{r}^{2}
\end{array}\right),  \tag{A,27}\\
& \not \chi_{e} \equiv\left(-\frac{i}{2 \pi^{2}}\right) \int_{-\infty}^{+\infty} d^{4} \ell\left\{\left(\ell^{\prime}+m_{c}\right) k\left(q_{5}+m_{c}\right)\right\}\left(\prod_{r=1}^{5} \frac{1}{q_{r}^{2}-m_{r}^{2}}\right) . \tag{A.28}
\end{align*}
$$

The loop integration can be performed as sketched above，with modifications due to the spin factors．In particular we have to remember the linear transforma－ tion $\ell^{\ell}=\ell-B / A$ ．By use of the integrals，Eqs。（A。1）－（A。4），we find：

$$
\begin{equation*}
\not Z_{a}=\int_{0}^{1}(\mathrm{~d} \alpha)^{4}\left\{\mathrm{~m}_{\mathrm{c}}-\not \mathrm{K}_{1}\right\} \circ \mathrm{I}_{\mathrm{a}}(\alpha) \tag{A.29}
\end{equation*}
$$

Here we introduce the convention

$$
\begin{align*}
& x_{1} \equiv-\not p_{1} \alpha_{2}+\not p_{2}\left(\alpha_{2}+\alpha_{3}\right)+\frac{k^{\prime}}{2}\left(\alpha_{2}+\alpha_{3}+\alpha_{4}\right)  \tag{A.30}\\
& x_{2} \equiv-\not p_{1}\left(\alpha_{2}+\alpha_{3}\right)+\not p_{2} \alpha_{2}+\frac{k^{\gamma}}{2}\left(\alpha_{2}+\alpha_{3}+\alpha_{4}\right) \tag{o}
\end{align*}
$$

The same analysis for diagram（c）leads to

$$
\begin{equation*}
\not Z_{c}=\int_{0}^{1}(\mathrm{~d} \alpha)^{4}\left\{\mathrm{~m}_{\mathrm{c}}+\not \ddot{x}_{2}\right\} \cdot \mathrm{I}_{\mathrm{c}}(\alpha) . \tag{A。32}
\end{equation*}
$$

The spin factor of diagram（e）is evaluated by dropping all terms linear in $\ell_{\mu}^{\prime}$ since their contributions vanish in the loop integration。 Using Eqs．（A．1）－ （A．4）we obtain

$$
\left.\begin{array}{rl}
\not Z_{e} & =\left(\frac{-\mathrm{i}}{2 \pi^{2}}\right) \int_{-\infty}^{+\infty} \mathrm{d}^{4} \ell\left\{\left(d_{1}+\mathrm{m}_{\mathrm{c}}\right) \notin\left(d_{5}+\mathrm{m}_{\mathrm{c}}\right)\right\}\left(\underset{\mathrm{r}=1}{\underset{\mathrm{M}}{\mathrm{r}}} \frac{1}{2}-\mathrm{m}_{\mathrm{r}}^{2}\right.
\end{array}\right)
$$

where again we have introduced the convention of writing

$$
\begin{equation*}
\not \gamma_{1}=k\left(\alpha_{4}+\alpha_{5}\right)+\frac{k^{\prime}}{2}\left(\alpha_{2}+\alpha_{3}-\alpha_{4}\right)-\not \dot{p}_{1} \alpha_{3} \tag{A.34}
\end{equation*}
$$

$$
\begin{equation*}
y_{2}=k\left(\alpha_{3}+\alpha_{4}+\alpha_{5}\right)+\frac{k^{\prime}}{2}\left(\alpha_{2}-\alpha_{3}-\alpha_{4}\right)+\not \phi_{1} \alpha_{3} \tag{A.35}
\end{equation*}
$$

Using the rule

$$
\begin{align*}
& Z_{\mathrm{b}}=Z_{\mathrm{a}}\left(\mathrm{p}_{1} \rightarrow-\mathrm{p}_{2}\right), \\
& \not K_{d}=Z_{\mathrm{c}}\left(\mathrm{p}_{1} \cdots-\mathrm{p}_{2}\right), \\
& Z_{f}=Z_{e}\left(p_{1} \mapsto-p_{2}\right), \tag{A.36}
\end{align*}
$$

one easily establishes the spin factors for diagrams（b），（d），and（f），as given in Eqs．（3．13）and（3．14）。 For simplicity of notation we sometimes use the sim－ plifying convention that，instead of writing the index of each diagram in $I_{j}(\alpha)$ ， we will rather use $s$ or $u$ in agreement with $D_{S}$ or $D_{u}$ of the particular diagram． The generalization of the above formalism to amplitudes describing spin－$\frac{1}{2} \mathrm{c}$－ quarks which interact via spin－1 gluons with the spinless nucleon is straight－ forward；we therefore only indicate modifications．

In the integrands of Eqs．（A．26）－（A。28）for $\mathbb{Z}_{j}$ ，the spin parts differ．We first consider diagram（a）．The curly bracket in $\Psi_{a}$ of $E q$ 。（ $\left.A_{0} 26\right)$ is replaced by

$$
\begin{equation*}
\left\{\left(\phi_{1}+\phi_{3}\right)\left(-l^{\prime}+m_{c}\right)\left(\phi_{3}+p_{2}\right)\right\} \tag{A.37}
\end{equation*}
$$

We now follow the same procedure as above：replacement of all internal mo－ menta by the external ones，replacement $\ell=l^{\prime}+B$ and subsequent rearrangement of terms as follows：

$$
\begin{aligned}
& \{0.0\}=\left(p_{1}+p_{2}+p_{4}-x x_{1}-\ell^{\prime}\right)\left(m_{c}-x_{1}-\ell^{\prime}\right)\left(2 p_{2}+p_{4}-x_{1}-\ell^{\prime}\right) \equiv\left(\phi_{1}-x^{\prime}\right)\left(x_{2}-\ell^{\prime}\right)\left(x_{3}-l^{\prime}\right)
\end{aligned}
$$

We have defined

$$
\begin{aligned}
& \not \phi_{1} \equiv \quad\left(\phi_{1} a_{1}+\not p_{2} b_{1}+k^{\prime} c_{1}\right), \\
& \not{ }_{2} \equiv m_{c}+\left(\phi_{1} a_{2}+\not p_{2} b_{2}+\not k^{\prime} c_{2}\right),
\end{aligned}
$$

$$
\begin{equation*}
\dot{x}_{3}^{\prime} \equiv\left(\phi_{1} \mathrm{a}_{3}+\not \phi_{2} \mathrm{~b}_{3}+k^{\prime} \mathrm{c}_{3}\right) \tag{A,39}
\end{equation*}
$$

where the $\mathrm{a}_{\mathrm{i}}, \ldots$. ，etc．，depend linearly on the integration parameters $\alpha_{0}$ In－ serting the definition of $k_{1}$ ，given in Eq。（A。30／31），into Eq。（ $A_{\circ} 38$ ）defines the expansion coefficients in terms of the integration parameters $\alpha$ ：

$$
\begin{align*}
& a_{1}=1+\alpha_{2}, \quad b_{1}=1-\alpha_{2}-\alpha_{3}, \quad c_{1}=\frac{1}{2} \alpha_{1} \\
& a_{2}=\alpha_{2}, \quad b_{2}=-\left(\alpha_{2}+\alpha_{3}\right), \quad c_{2}=-\frac{1}{2}\left(1-\alpha_{1}\right), \\
& a_{3}=\alpha_{2}, \quad b_{3}=2-\left(\alpha_{2}+\alpha_{3}\right), \quad c_{3}=\frac{1}{2} \alpha_{1} \tag{A.40}
\end{align*}
$$

Using the integration formulas in Eqs．（A．1）－（A。4）in order to perform the $d^{4} \ell$ integration，one finds

$$
\begin{equation*}
\phi_{\mathrm{a}} \equiv \not \forall_{1} \not \not_{2} \not \phi_{3}+2 \mathrm{D}_{\mathrm{s}}\left(\not \psi_{1}+\not \dot{\phi}_{3}\right)+\frac{1}{2} \mathrm{D}_{\mathrm{s}} \gamma_{\mu} \not \dot{x}_{2} \gamma^{\mu} \tag{A.41}
\end{equation*}
$$

We now consider the modifications in diagram（c）due to spin－1 gluon exchange． The curly bracket in the integrand of Eq。（A．27）is replaced by

$$
\begin{equation*}
\left\{\left(\phi_{1}-q_{3}\right)\left(\ell+m_{c}\right)\left(\phi_{2}-\not q_{3}\right)\right\} \tag{A.42}
\end{equation*}
$$

In principle we now could go through all modifications as before．In the explicit evaluation of the helicity matrix elements，however，we found it more convenient to take advantage of the relation $\sharp_{c}=-\not Z_{a}\left(p_{1} \leftrightarrow-p_{2}, m_{c} \rightarrow-m_{c}\right)$ ．This therefore leads to $\mathscr{S}_{c}=-\Phi_{a}\left(w_{i}\right)$ with

$$
\begin{array}{ll}
w_{1} \equiv & \left(-\not p_{2} a_{1}-\not p_{1} b_{1}+k^{\prime} c_{1}\right), \\
w_{2} & \equiv-m_{c}+\left(-\not p_{2} a_{2}-\not p_{1} b_{2}+\not k^{\imath} c_{2}\right), \\
w_{3} \equiv & \left(-\not p_{2} a_{3}-\not b_{1} b_{3}+\not k^{\prime} c_{3}\right) \tag{A.43}
\end{array}
$$

All $a_{i} . .$. are chosen as for diagram（a）and are specified in EqS．（A．40）．
The spin factors for diagrams（b）and（d）are determined by the replacement $\mathrm{p}_{1} \leftrightarrow-\mathrm{p}_{2}$ in those of diagrams（a）and（c）。 This does not modify the form of $\Phi_{a}$
as a function of the $\phi_{i}$ ；however，it does change the expansion coefficients $\mathrm{a}_{\mathrm{i}} \ldots$ （as fuñctions of the integration parameters $\alpha$ ）in the $x_{i}$ according to：

$$
\begin{align*}
& a_{1}=-1+\left(\alpha_{2}+\alpha_{3}\right), \quad b_{1}=-\left(1+\alpha_{2}\right), \quad c_{1}=\frac{1}{2} \alpha_{1}, \\
& a_{2}=\left(\alpha_{2}+\alpha_{3}\right), \quad b_{2}=-\alpha_{2}, \quad c_{2}=-\frac{1}{2}\left(1-\alpha_{1}\right), \\
& a_{3}=-2+\left(\alpha_{2}+\alpha_{3}\right), \quad b_{3}=-\alpha_{2}, \quad c_{3}=\frac{1}{2} \alpha_{1} . \tag{A.44}
\end{align*}
$$

To summarize，all spin factors $\$_{a}, \ldots, \$_{d}$ are given by Eq。（3．34）as a function of the $v_{i}\left(w_{i}\right)$ 。Differences in the spin factors arise in the expansion coefficients of these quantities．$a_{i} \ldots$ for diagrams（a）and（c）are given in Eq．（A．40）， whereas the ones for diagrams（b）and（d）are given in Eq．（A．44）。

We now determine the spin factors of diagrams（e）and（f）．The curly bracket in the integrand of $\sharp_{e}$ in Eq。（A。28）is replaced by

$$
\begin{equation*}
\left\{\left(\phi_{1}+q_{3}\right)\left(\phi_{1}+m_{c}\right) \phi\left(\phi_{5}+m_{c}\right)\left(\phi_{3}+\not \phi_{2}\right)\right\}, \tag{A.45}
\end{equation*}
$$

which，by writing the internal momenta in terms of the external momenta and the loop momentum $\ell^{\prime}$ ，may be cast into the form：

$$
\begin{equation*}
\{\ldots \ldots\} \equiv\left(f_{1}+\ell^{\prime}\right)\left(\mathrm{m}_{\mathrm{c}}+\not \phi_{2}+\ell^{\prime}\right) \notin\left(\mathrm{m}_{\mathrm{c}}+\not \ell_{3}+\ell^{\prime}\right)\left(\not 女_{4}+\ell^{\prime}\right) \tag{A.46}
\end{equation*}
$$

where

$$
\begin{equation*}
\not x_{i} \equiv \not p_{1} \quad a_{i}+k \quad b_{i}+\not k^{\prime} \quad c_{i} \quad(i=1, \ldots, 4) \tag{A.47}
\end{equation*}
$$

The curly bracket is expanded in $\ell^{\prime}$ and the $d^{4} \ell$ integration is performed using EqS．（A．1）－（A．4）．All terms with an odd number of $\ell^{\prime}$ vanish upon integration， leading to

$$
\begin{equation*}
\phi_{\mathrm{e}} \equiv \$_{\mathrm{e}_{1}}+\$_{\mathrm{e}_{2}}+\$_{\mathrm{e}_{3}} \tag{A.48}
\end{equation*}
$$

whose explicit forms are given in Eqs．（3．45）－（3．47）．
The same reasoning for diagram（f）leads to $\mathscr{A}_{f} \equiv \mathscr{A}_{e}\left(v_{i}\right)$ and the two ex－ pressions differ only in the expansion coefficients $v_{i}$ as a function of the
integration parameters $\alpha$. The coefficients in the $\mathrm{v}_{\mathbf{i}}$ are easily evaluated and we find for diagram (e):

$$
\begin{align*}
& \mathrm{a}_{1}=2-\alpha_{3}, \quad \mathrm{~b}_{1}=\alpha_{4}+\alpha_{5}, \quad \mathrm{c}_{1}=\frac{1}{2}\left(\alpha_{2}+\alpha_{3}-\alpha_{4}-1\right), \\
& a_{2}=-\alpha_{3}, \quad b_{2}=\alpha_{4}+\alpha_{5}, \quad c_{2}=\frac{1}{2}\left(\alpha_{2}+\alpha_{3}-\alpha_{4}\right), \\
& \mathrm{a}_{3}=-\alpha_{3}, \quad \mathrm{~b}_{3}=\alpha_{4}+\alpha_{5}-1, \quad \mathrm{c}_{3}=\frac{1}{2}\left(\alpha_{2}+\alpha_{3}-\alpha_{4}\right), \\
& \mathrm{a}_{4}=2-\alpha_{3}, \quad \mathrm{~b}_{4}=\alpha_{4}+\alpha_{5}+1, \quad \mathrm{c}_{4}=\frac{1}{2}\left(\alpha_{2}+\alpha_{3}-\alpha_{4}-3\right) \text {, } \tag{A.49}
\end{align*}
$$

and for diagram (f):

$$
\begin{array}{lll}
a_{1}=\alpha_{3}-2, & b_{1}=\alpha_{3}+\alpha_{4}+\alpha_{5}-2, & c_{1}=\frac{1}{2}\left(\alpha_{2}-\alpha_{3}-\alpha_{4}+3\right), \\
a_{2}=\alpha_{3}, & b_{2}=\alpha_{3}+\alpha_{4}+\alpha_{5}, & c_{2}=\frac{1}{2}\left(\alpha_{2}-\alpha_{3}-\alpha_{4}\right), \\
a_{3}=\alpha_{3}, & b_{3}=\alpha_{3}+\alpha_{4}+\alpha_{5}-1, & c_{3}=\frac{1}{2}\left(\alpha_{2}-\alpha_{3}-\alpha_{4}\right), \\
a_{4}=\alpha_{3}-2, & b_{4}=\alpha_{3}+\alpha_{4}+\alpha_{5}-1, & c_{4}=\frac{1}{2}\left(\alpha_{2}-\alpha_{3}-\alpha_{4}+1\right) . \tag{A,50}
\end{array}
$$

## APPENDIX B

Here we give details of the "spin amplitudes" $Q_{i}$, defined in Eq. (3.18) and (3.23). In order to clarify our notation, we define the momenta and wavefunctions.

The momentum 4-vectors in the CM-system are:

$$
\begin{align*}
& k^{\mu}=(k, 0,0, k), \quad k^{\prime} \mu=\left(E^{\prime}, k^{\prime} \sin \theta, 0, k^{\prime} \cos \theta\right)  \tag{B.1}\\
& p_{1}^{\mu}=\left(E_{1}, 0,0,-k\right), \quad p_{2}^{\mu}=\left(E_{2},-k^{\prime} \sin \theta, 0,-k^{\prime} \cos \theta\right) \tag{B.2}
\end{align*}
$$

We have used the following spin $1 / 2$ wave functions:

$$
\begin{align*}
& u_{+}=\left[\begin{array}{l}
F_{+} \cos \frac{\theta}{2} \\
F_{+} \sin \frac{\theta}{2} \\
F_{-} \cos \frac{\theta}{2} \\
F_{-} \sin \frac{\theta}{2}
\end{array}\right], \quad u_{-}=\left[\begin{array}{l}
F_{+} \sin \frac{\theta}{2} \\
F_{+} \cos \frac{\theta}{2} \\
F_{-} \sin \frac{\theta}{2} \\
-F_{-} \cos \frac{\theta}{2}
\end{array}\right], F_{ \pm}=\sqrt{\frac{\frac{1}{2} E^{\prime}+m_{c}}{2 m_{c}}}, \\
& \mathrm{v}_{+}=\left[\begin{array}{l}
\mathrm{F}_{-} \sin \frac{\theta}{2} \\
-\mathrm{F}_{-} \cos \frac{\theta}{2} \\
-\mathrm{F}_{+} \sin \frac{\theta}{2} \\
\mathrm{~F}_{+} \cos \frac{\theta}{2}
\end{array}\right], \quad \mathrm{v}_{-}=\left[\begin{array}{l}
-\mathrm{F}_{-} \cos \frac{\theta}{2} \\
-\mathrm{F}_{-} \sin \frac{\theta}{2} \\
-\mathrm{F}_{+} \cos \frac{\theta}{2} \\
-\mathrm{F}_{+} \sin \frac{\theta}{2}
\end{array}\right], \tag{B.3}
\end{align*}
$$

and the photon polarization vectors read:

$$
\epsilon_{ \pm}=\frac{1}{\sqrt{2}}\left[\begin{array}{r}
0  \tag{B.4}\\
\mp 1 \\
-\mathrm{i} \\
0
\end{array}\right]
$$

We comment about the definition of our spinors. Since the c $\bar{c}$-state describes a particle of spin-1, we have chosen the phase convention of the spinors in agreement with the phase of the spin-1 helicity polarization of a particle moving in the direction $\overline{\mathrm{k}}(\theta)$ 。 This demands that in constructing the $\overline{\mathrm{c}}$-spinor $\mathrm{v}_{1}$, the antiquark has to be considered as a 2 -state in the sense of Jacob and Wick, ${ }^{10}$ which finally results in the change :

$$
\begin{equation*}
\mathrm{v}_{\lambda} \rightarrow(-1)^{\frac{1}{2}-\lambda} \cdot \mathrm{v}_{\lambda} . \tag{B.5}
\end{equation*}
$$

The spinors in Eq。 ( $\mathrm{B}, 3$ ) have been obtained by a simple boost and rotation $\theta$ and do not contain this change. The above phase convention, however, has been taken into account in the matrix elements, EqS.(3.18) and (3.23).

The calculation of the "spin amplitudes":

$$
\begin{equation*}
\left\langle\lambda_{1} \lambda_{2}\right| Q_{i}\left|\lambda_{\gamma}=+1\right\rangle \equiv Q_{i}\left(\lambda_{1} \lambda_{2}\right) \tag{B.6}
\end{equation*}
$$

is straightforward and we therefore list here only a few examples
$\mathrm{Q}_{1}(++)=-\sqrt{8} \cos ^{2} \frac{\theta}{2} \mathrm{k}\left[\left(\mathrm{E}_{1}+\mathrm{k}\right)+2 \mathrm{k}^{\prime} \sin ^{2} \frac{\theta}{2}\right] \quad \stackrel{\mathrm{s} \rightarrow \infty}{\Longrightarrow}-\sqrt{2}\left(\mathrm{~s}-\mathrm{m}_{\mathrm{N}}^{2}\right)$,
$Q_{1}(-+)=\sin \theta\left(\frac{1}{m_{c}}\right)\left[E_{1}\left(E^{\prime} k-E_{1} k\right)+E^{\prime} k^{2}\left(1-\frac{k^{\prime}}{k} \cos \theta\right)\right] \Longrightarrow \frac{\sqrt{-t}}{m_{c}}\left(-\frac{t}{2}+4 m_{c}^{2}\right)$,
$Q_{1}(--)=-\sqrt{8} \sin ^{2} \frac{\theta}{2} k\left[\left(\mathrm{E}_{1}+\mathrm{k}\right)-2 \mathrm{k}^{\mathrm{\rho}} \cos ^{2} \frac{\theta}{2}\right] \quad \Rightarrow-\sqrt{2} \frac{\mathrm{t}}{\mathrm{s}}\left(\mathrm{t}-4 \mathrm{~m}_{\mathrm{c}}^{2}+\mathrm{m}_{\mathrm{N}}^{2}\right)$,
and so on.

## APPENDIX C

Here we list the expansion coefficients $\xi, \eta, \zeta, \ldots$, in the amplitudes $M_{j}(p, \alpha)$ in Eqs. $(3.38)$ and (3.39):

$$
\begin{align*}
\underline{\mathrm{M}_{\mathrm{a}}}: \xi_{1} & =+\frac{1}{\sqrt{8}}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\eta_{1} & =-\frac{\sqrt{2}}{16}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\xi_{1} & =-\frac{\sqrt{2}}{8}\left(4 \alpha_{1}-\alpha_{1} \alpha_{3}+\alpha_{1}^{2} \alpha_{3}\right)  \tag{C.1}\\
\mathrm{M}_{\mathrm{b}}: \quad \xi_{1} & =+\frac{1}{\sqrt{8}}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\eta_{1} & =-\frac{\sqrt{2}}{16}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\zeta_{1} & =+\frac{\sqrt{2}}{8}\left(4 \alpha_{1}-\alpha_{1} \alpha_{3}+\alpha_{3} \alpha_{1}^{2}\right)  \tag{C.2}\\
\mathrm{M}_{\mathrm{c}}: \quad \xi_{1} & =+\frac{1}{\sqrt{8}}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\eta_{1} & =+\frac{\sqrt{2}}{16}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\zeta_{1} & =+\frac{\sqrt{2}}{8}\left(\alpha_{1} \alpha_{3}\left(1-\alpha_{1}\right)\right.  \tag{C.3}\\
\mathrm{M}_{\mathrm{d}}: \quad \xi_{1} & =+\frac{1}{\sqrt{8}}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\underline{\eta_{1}} & =+\frac{\sqrt{2}}{16}\left(1-\alpha_{1}\right)\left(2-\alpha_{3}\right)^{2} \\
\zeta_{1} & =-\frac{\sqrt{2}}{8} \alpha_{1} \alpha_{3}\left(1-\alpha_{1}\right) \tag{C.4}
\end{align*}
$$

The phase convention Eq. ( $\mathrm{B}, 5$ ) for the V -spinor has been taken into account. The expansion coefficients $\left(\xi_{5}, \eta_{5}, \zeta_{5}\right)$ in $E q$ 。 $(3,44)$ hide a $\ln ^{2}(-s)$ dependence; their explicit forms are:

$$
\begin{align*}
\frac{\mathrm{M}_{\mathrm{a}}: \xi_{5}}{} & =3 \alpha_{3}-8, & \quad \mathrm{M}_{\mathrm{b}}: \xi_{5} & =-3 \alpha_{3}+8 \\
\eta_{5} & =-3 \alpha_{3}+8, & \eta_{5} & =3 \alpha_{3}-8 \\
\zeta_{5} & =\frac{1}{2}\left(3 \alpha_{1}-1\right), & \zeta_{5} & =\frac{1}{2}\left(3 \alpha_{1}-1\right), \tag{C.5,6}
\end{align*}
$$

$$
\begin{align*}
& \underline{\mathrm{M}_{\mathrm{c}}}: \xi_{5}=3 \alpha_{3}-8, \quad \underline{\mathrm{M}_{\mathrm{d}}}: \xi_{5}=-3 \alpha_{3}+8, \\
& \eta_{5}=3 \alpha_{3}-8, \quad \eta_{5}=-3 \alpha_{3}+8, \\
& \zeta_{5}=\frac{1}{2}\left(3 \alpha_{1}-1\right), \quad \zeta_{5}=\frac{1}{2}\left(3 \alpha_{1}-1\right) . \tag{C.7,8}
\end{align*}
$$

The expansion coefficients appearing in the amplitudes of the nonplanar diagrams
(e) and (f) are:

$$
\begin{align*}
\mathrm{M}_{\mathrm{e}_{1}}: \xi_{1}= & \frac{1}{\sqrt{2}}\left[\left(2-\alpha_{3}\right)\left(1-\alpha_{2}-\alpha_{3}-\alpha_{4}-2 \alpha_{5}\right)\right] \\
\eta_{1}= & \frac{\sqrt{2}}{4}\left[\left(2-\alpha_{3}\right)\left(\alpha_{4}+\alpha_{5}\right)\right], \\
\zeta_{1}= & \frac{\sqrt{2}}{4}\left[1+\left\{1+2 \alpha_{4}+2 \alpha_{5}\right\}\left\{2+\alpha_{2}-\alpha_{3}-\alpha_{4}\right\}\right],  \tag{C.9}\\
\mathrm{M}_{\mathrm{e}_{2}}: \xi_{1}= & -\frac{\sqrt{2}}{4}\left(2-\alpha_{3}\right)^{2}, \\
\eta_{1}= & +\frac{\sqrt{2}}{4}\left[\left(2-\alpha_{3}\right)\left(3+\alpha_{2}-\alpha_{3}-\alpha_{4}\right)\right], \\
\xi_{1}= & +\frac{\sqrt{2}}{8}\left[\left(2-\alpha_{3}\right)\left(\alpha_{2}+\alpha_{3}-\alpha_{4}\right)\right],  \tag{C.10}\\
\mathrm{M}_{3}: \xi_{1}= & \frac{\sqrt{2}}{4} \alpha_{3}\left[\alpha_{3}^{3}+\alpha_{3}^{2} \cdot \mathrm{~A}_{2}+\alpha_{3} \cdot \mathrm{~A}_{1}+\mathrm{A}_{0}\right], \\
& \mathrm{A}_{0} \equiv-2\left(1-\alpha_{2}-\alpha_{4}-2 \alpha_{5}\right)^{2}, \\
\eta_{1}= & -\frac{\sqrt{2}}{16}\left[\alpha_{3}^{4}+\alpha_{3}^{3} \cdot \Lambda_{3}+\alpha_{3}^{2} \cdot \mathrm{~A}_{2}+\alpha_{3} \cdot \mathrm{~A}_{1}+\mathrm{A}_{0}\right] \\
& \mathrm{A}_{0} \equiv 4\left\{\left(\alpha_{2}^{2}-\alpha_{4}^{2}\right)+2\left(\alpha_{5}-1\right)\left(\alpha_{2}-\alpha_{4}\right)\right\}, \\
\zeta_{1}= & -\frac{\sqrt{2}}{8}\left[\alpha_{3}^{4} \cdot \mathrm{~A}_{4}+\alpha_{3}^{3} \cdot \mathrm{~A}_{3}+\alpha_{3}^{2} \circ \mathrm{~A}_{2}+\alpha_{3} \cdot \mathrm{~A}_{1}+\mathrm{A}_{0}\right] \\
& \mathrm{A}_{0} \equiv\left\{4\left(\alpha_{2}^{2}-\alpha_{4}^{2}\right)+\left(8 \alpha_{5}-2\right)\left(\alpha_{2}-\alpha_{4}\right)\right\},  \tag{C.11}\\
\mathrm{M}_{f_{1}}: \xi_{1}= & -\frac{1}{\sqrt{2}}\left[\left(2-\alpha_{3}\right)\left(1-\alpha_{2}-\alpha_{3}-\alpha_{4}-2 \alpha_{5}\right)\right]
\end{align*}
$$

$$
\begin{align*}
& \eta_{1}=+\frac{\sqrt{2}}{4}\left[\left(2-\alpha_{3}\right)\left(2-\alpha_{3}-\alpha_{4}-\alpha_{5}\right)\right], \\
& \zeta_{1}=+\frac{\sqrt{2}}{4}\left[1+\left\{2-\alpha_{2}-\alpha_{3}+\alpha_{4}\right\}\left\{3-2 \alpha_{3}-2 \alpha_{4}-2 \alpha_{5}\right\}\right] \text {, }  \tag{C.12}\\
& \mathrm{M}_{\mathrm{f}_{2}}: \xi_{1}=-\frac{\sqrt{2}}{4}\left(2-\alpha_{3}\right)^{2} \text {, } \\
& \eta_{1}=+\frac{\sqrt{2}}{4}\left[\left(2-\alpha_{3}\right)\left(1-\alpha_{2}-\alpha_{3}+\alpha_{4}\right)\right], \\
& \zeta_{1}=-\frac{\sqrt{2}}{8}\left[\left(2-\alpha_{3}\right)\left(\alpha_{2}-\alpha_{3}-\alpha_{4}\right)\right] \text {, }  \tag{C.13}\\
& \underline{\mathrm{M}_{\mathrm{f}_{3}}}: \xi_{1}=-\frac{\sqrt{2}}{4} \alpha_{3}\left[\alpha_{3}^{3}+\alpha_{3}^{2} \cdot \mathrm{~A}_{2}+\alpha_{3} \cdot \mathrm{~A}_{1}+\mathrm{A}_{0}\right] \text {, } \\
& A_{0} \equiv-2\left(1-\alpha_{2}-\alpha_{4}-2 \alpha_{5}\right)^{2}, \\
& \eta_{1}=-\frac{\sqrt{2}}{16} \cdot\left[\alpha_{3}^{4}+\alpha_{3}^{3} \cdot \mathrm{~A}_{3}+\alpha_{3}^{2} \cdot \mathrm{~A}_{2}+\alpha_{3} \cdot \mathrm{~A}_{1}+\mathrm{A}_{0}\right], \\
& A_{0} \equiv 4\left\{\left(\alpha_{2}^{2}-\alpha_{4}^{2}\right)+2\left(\alpha_{5}-1\right)\left(\alpha_{2}-\alpha_{4}\right)\right\}, \\
& \zeta_{1}=-\frac{\sqrt{2}}{8}\left[\alpha_{3}^{4} \cdot \mathrm{~A}_{4}+\alpha_{3}^{3} \cdot \mathrm{~A}_{3}+\alpha_{3}^{2} \cdot \mathrm{~A}_{2}+\alpha_{3} \cdot \mathrm{~A}_{1}+\mathrm{A}_{0}\right], \\
& A_{0} \equiv\left\{4\left(\alpha_{2}^{2}-\alpha_{4}^{2}\right)+\left(8 \alpha_{5}-6\right)\left(\alpha_{2}-\alpha_{4}\right)\right\} . \tag{C.14}
\end{align*}
$$

## FIGURE CAPTIONS

1．Lêpton decay of the photoproduced $\psi$－resonance。
2．$\psi$－photoproduction in a picture of quarks interacting via gluons．
3．Photoproduction of $\psi \equiv(c \bar{c})$ as viewed in a two－gluon exchange model．
4．Integration region for integral（4．54）。
5．Size and $t$－dependence of residue functions $f_{t}(\xi)$ appearing in the asymptotic form of the amplitudes of diagrams（a）－（d）．

6．Size and $t$－dependence of residue functions $h_{t}(\xi)$ appearing in the asymptotic form of the amplitudes of diagrams（e）and（f）。

7．$m_{G}$－dependence of residue functions $f_{t}(1)$（Eq．（3．51））and $h_{t}(1)$（Eq．（3．58））． This behavior is representative of all integrals of the same type

8．$m_{V}$－dependence of residue functions $f_{t}$ and $h_{t}$ given in Eqs。（3．51）and（3．58）．
9．Two－gluon exchange model with vector gluons．Density matrix element $\rho_{00}^{0}$ for $\rho$－and $\psi$－photoproduction as a function of the gluon mass $\mathrm{m}_{\mathrm{G}}$ in the region where the nonflip amplitude vanishes（peak）．The kinematical vari－ ables are $s=30 \mathrm{GeV}^{2}, \mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ 。
10．Two－gluon exchange model with vector gluons．Density matrix element $\rho_{00}^{0}$ for $\rho$－and $\psi$－photoproduction as a function of the gluon mass $m_{G}$ in the region where the nonflip amplitude vanishes（peak）．The kinematical vari－ ables are $\mathrm{s}=30 \mathrm{GeV}^{2}, \mathrm{t}=-2.0(\mathrm{GeV} / \mathrm{c})^{2}$ ．
11．Position of the peak（in Fig。9）as a function of $m_{V}$ and $m_{G}$ for $s=30 \mathrm{GeV}^{2}$ and $\mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ 。
12．Two－gluon exchange model with vector gluons．Gluon mass dependence and relative size of the flip and nonflip amplitudes（in arbitrary units）for $\psi$－ photoproduction．The kinematical variables are $\mathrm{s}=30 \mathrm{GeV}^{2}, \mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ 。

13．Two－gluon exchange model with vector gluons．Gluon mass dependence of
the nonflip amplitude for $\psi$-photoproduction. The amplitudes of diagrams (a) - (d) and diagrams (e) and (f) are presented separately. The kinematical variables are $s=30 \mathrm{GeV}^{2}, \mathrm{t}=-0.2(\mathrm{GeV} / \mathrm{c})^{2}$ 。
14. Two-gluon exchange model with vector gluons. t-dependence of $\rho_{00}^{0}$ for $\rho$ photoproduction at the peak. The gluon mass was chosen to be $\mathrm{m}_{\mathrm{G}}=0.04 \mathrm{GeV}$.
15. Two-gluon exchange model with vector gluons. t-dependence of $\rho_{00}^{0}$ for $\psi$ photoproduction at the peak. The gluon mass was chosen to be $m_{G}=$ 1.0 GeV .
