$Q_{1}(1290)$ AND $Q_{2}(1400)$ DECAY RATES
AND THEIR SU(3) IMPLICATIONS*

#### Abstract

We summarize and combine the known information on the decay rates of the strangeness-one axial vector mesons, $Q_{1}$ and $Q_{2}$. From this information and the rate for $B \rightarrow \omega \pi$, we determine the $Q_{A}-Q_{B}$ mixing angle and the S-wave, symmetric and antisymmetric octet couplings for vector-pseudoscalar decays of axial vector mesons. If we assume the $\mathrm{D}(1285)$ and the $\mathrm{E}(1420)$ belong to the $\mathrm{J}^{\mathrm{PC}}=1^{++}$nonet, we find the $\mathrm{A}_{1}$ to have a mass of $\sim 1.47 \mathrm{GeV}$ and a large (>. 3 GeV ) width。

[^0]Of the four $\ell=1$ ，$q \bar{q}$ nonets expected from the three－－quark model［1］，only the $A_{2}$ nonet $^{\dagger}$ is well established $[2,3]$ ，while the $\delta$ nonet at least has sufficient candidates $[3,4]$ 。 In contrast，even good candidates for the two axial vector nonets have been elusive．Only the namesake of the B nonet is clearly estab－ lished［5，3］，while the $D(1285)$ and，possibly，${ }^{\dagger \dagger}$ the $E(1420)$ may be identified with the $A_{1}$ nonet．The lack of experimental confirmation of the axial vector nonet states remains a nagging problem for quark model phenomenology．

Recently，however，evidence for two strangeness－one，axial vector mesons was obtained from partial wave analyses［7，8］of diffractively produced $\mathrm{K}^{ \pm} \pi^{+} \pi^{-}$ systems．Subsequently，fits to the partial wave mass spectra of ref．［7］were made in two studies［9，10］using rather different models for the partial wave amplitudes．${ }^{\dagger \dagger \dagger}$ These fits yield information on the masses，total widths，and $K * \pi, \rho \mathrm{~K}$ couplings of $\mathrm{Q}_{1}(1290)$ and $\mathrm{Q}_{2}(1400)$ 。We combine that information with other branching ratios to $\omega \mathrm{K}[12,13]$ and $\kappa \pi, \epsilon \mathrm{K}[14]$ to obtain two complete sets of $Q_{1}$ and $Q_{2}$ partial widths．With the model－dependent uncertainties of refs．［9］and［10］in mind，we obtain from these two sets of partial widths a conservative estimate of the decay rates for $Q$ mesons．From this estimate and the rate for $B \rightarrow \omega \pi$ ，we determine the $S$－wave，octet couplings $g_{A}$（anti－ symmetric）and $g_{B}$（symmetric）for vector－pseudoscalar（V－PS）decays of axial vector mesons as well as the $Q_{A}-Q_{B}$ mixing［15］angle，$\theta_{Q^{\circ}}$ ．Identifying the $D$

[^1]and E with the $A_{1}$ nonet isosinglets, we can then compute the mass and $\rho \pi$ width of the $A_{1}$ 。

To combine the diverse information on $Q$ decays, we use the fact that the total width is the sum of all (known) partial widths. From refs. [9] and [10], we fix the total width and $\mathrm{K}^{*} \pi / \rho \mathrm{K}$ branching ratio. For $\kappa \pi$ and $\epsilon \mathrm{K}$ decays, we use our observed cross section ratios [14]: $\Gamma\left(\mathrm{Q}_{1} \rightarrow \kappa \pi\right) / \Gamma\left(Q_{1} \rightarrow \rho K\right)=0.35 \pm$ $.08, \Gamma\left(Q_{1} \rightarrow \epsilon K\right) / \Gamma\left(Q_{1} \rightarrow \rho K\right)=0.3 \pm .1$, and $\Gamma\left(Q_{2} \rightarrow \epsilon K\right) / \Gamma\left(Q_{2} \rightarrow K * \pi\right)=0.2 \pm$ -1. For $Q_{1} \rightarrow \epsilon K$ we have assumed a $10 \%$ background (tail of $Q_{2}$ ), and for $Q_{2}$ $\rightarrow \epsilon \mathrm{K}$ we have inflated the error to accommodate a possibly large background in the $K^{*} \pi$ mode. The branching ratio $\mathrm{Q}_{1} \rightarrow \omega \mathrm{~K} / \mathrm{Q}_{1} \rightarrow \rho \mathrm{~K}$ is more difficult to estimate. Because of the narrow $\omega$ width, the ratio of $\omega \mathrm{K}$ to $\rho \mathrm{K}$ phase space exhibits [13] a roughly step-function behavior at $\sim 1.28 \mathrm{GeV}$. Thus this branching ratio is extremely sensitive to the precise value of the $Q_{1}$ mass. Consequently we choose to use the upper limit $[13,12] \Gamma\left(Q_{1} \rightarrow \omega \mathrm{~K}\right) / \Gamma\left(Q_{1} \rightarrow \rho K\right) \leq$ $0.32 \pm .03$ 。

Combining the above information, we obtain columns two and three of table I, corresponding to the input of refs. [9] and [10] respectively. We have used from ref. [10] the results of the "original model" fit in which the $\operatorname{SU}(3), Q_{A}{ }^{-}$ $Q_{B}$ mixing constraints were not imposed. We comment on several important fcatures. First, although the $Q_{1} \rightarrow \rho K$ width is the principal contribution, it corresponds to, at best, only half the total width of $Q_{1}$. Secondly, both models indicate that $Q_{1}$ decouples from $K^{*} \pi$ while $Q_{2}$ decouples from $\rho \mathrm{K}$. This coupling pattern was central to the qualitative interpretation of the $I^{+} K^{*} \pi-\rho \mathrm{K}$ relative phase motion in terms of two $Q$ mesons as discussed in ref. [7]. Thirdly, there is a substantial difference in the magnitudes of the widths from the two models. Basically this reflects the uncertainty in the amount of coherent
background under $Q_{2}$ in the $K^{*} \pi$ channel．Quantitatively，it corresponds to the very đifferent parametrizations employed in the fits of refs。［9］and［10］。As an attempt to reflect such systematic uncertainties，we offer in the fourth col－ umn of table I a conservative estimate of the partial widths for $Q_{1}$ and $Q_{2}$ ，cor－ responding to the mean and standard deviation of the values and errors in the preceding columns．For comparison，the last column of table I corresponds to the $\operatorname{SU}(3)$ constrained fit of ref．［10］．We note that this fit provides a mildly worse［10］description of the partial wave data and that the ratio $\Gamma\left(Q_{1} \rightarrow \rho \mathrm{~K}\right) /$ $\Gamma\left(Q_{2} \rightarrow K^{*} \pi\right)$ is roughly $1 / 3$ that in the unconstrained fit．All the V－PS widths in table I are for S－wave decay，as the D－wave coupling is known to be small or nonexistent $[7,8]$ 。

We now turn to the extraction of $\operatorname{SU}(3)$ parameters from the information of table I．For V－PS decays of the axial vector（A）mesons，we define the reduced couplings $\gamma(\mathrm{A} \rightarrow \mathrm{V}-\mathrm{PS})$ by the formula

$$
\begin{equation*}
\Gamma(\mathrm{A} \rightarrow \mathrm{~V}-\mathrm{PS})=\frac{\left\langle\mathrm{q}_{\mathrm{V}}\right\rangle}{\mathrm{M}_{\mathrm{A}}^{2}} \gamma^{2}(\mathrm{~A} \rightarrow \mathrm{~V}-\mathrm{PS}) \tag{1}
\end{equation*}
$$

where $\left\langle q_{V}\right\rangle$ is the vector meson momentum averaged over its line shape［13］． These couplings are presented in the upper half of table II．They follow from the corresponding widths of table $I$ ，with the exception of $Q_{1} \rightarrow \omega \mathrm{~K}$ 。 In this case we use $\gamma^{2}\left(Q_{1} \rightarrow \omega K\right)=(.22 \pm .07) \gamma^{2}\left(Q_{1} \rightarrow \rho K\right)$ ，which is independent of the pre－ cise mass of $Q_{1}[13]$. We will also need the s－wave coupling ${ }^{\dagger}$ for $B \rightarrow \omega \pi$ ， $|\gamma(B \rightarrow \omega \bar{\pi})|=.72 \pm .03 \mathrm{GeV}$ ，assuming nominal values［3，5］for the mass， total width，and $D / S$ ratio．

In the usual spirit of $\operatorname{SU}(3)$ phenomenology［2］，we assume that symmetry breaking effects are accounted for by using observed masses in the phase space

of eq. (1), while the reduced couplings are related by exact $\mathrm{SU}(3)$, modified by vector meson singlet-octet mixing. In addition we assume that the physical $Q$ meson states are mixtures [15], characterized by an angle $\theta_{Q}$, of the $Q_{A}$ and $Q_{B}$ states. We may now relate the observed couplings for $Q_{I}$ and $Q_{2} V-P S$ decays to $g_{A}, g_{B}, \theta_{Q}$, and the symmetric singlet coupling, $g_{1}$. These relations are given in table III. As our final assumption, we set $\gamma(\mathrm{B} \rightarrow \phi \pi)=0$ on experimental grounds [3]。 This relates $g_{1}$ to $g_{B}$ through

$$
\begin{equation*}
\mathrm{g}_{1}=-\mathrm{g}_{\mathrm{B}} \cot \theta_{\mathrm{V}} / \sqrt{5} \tag{2}
\end{equation*}
$$

where we take [2] $\theta_{V}=-31^{\circ} \pm 3^{\circ}$ 。
Qualitatively the observed pattern of the V-PS couplings for $Q_{1}$ and $Q_{2}$ can be readily understood by careful inspection of table III. Thus, if we simply set $\mathrm{g}_{\mathrm{A}} / \mathrm{g}_{\mathrm{B}}=-6 / \sqrt{20}$ and $\theta_{\mathrm{Q}}=45^{\circ}$, we find $\gamma\left(\mathrm{Q}_{1} \rightarrow \mathrm{~K}^{*} \pi\right)=0$ and $\gamma\left(\mathrm{Q}_{2} \rightarrow \rho \mathrm{~K}\right)=0$; that is, we predict that $Q_{1}$ decouples from $K^{*} \pi$ and $Q_{2}$, from $\rho K$. In addition, for magically mixed [16] $\omega-\phi$, we have $\gamma(\omega \mathrm{K}) / \gamma(\rho \mathrm{K})=-1 / \sqrt{3}$ for both $\mathrm{Q}^{\prime} \mathrm{s}$. This is in rough accord with the observed ratio for $Q_{1}$ (table II); since $Q_{2}$ decouples from $\rho \mathrm{K}$, we would also expect it to decouple from $\omega \mathrm{K}$ (table I). Of course a set of relations similar to those of table III may be written for scalar-pseudoscalar (S-PS) Q meson decays. For $\theta_{Q}=45^{\circ}$, a ratio of $h_{A}$ to $h_{B}$ (the S-PS analogues of $g_{A}$ and $g_{B}$ ) may be chosen to have $Q_{2}$ decouple from $\kappa \pi$ (table $I$ ). Such a ratio would predict comparable couplings of $Q_{1}$ and $Q_{2}$ to $\kappa \eta$, the phase space being similar to that for the $\in K$ mode. However, the $\epsilon K$ decays involve not only $h_{A}$, $h_{B}$, and $\theta_{Q}^{-}$but also $h_{1}$ and the complications of $\epsilon, S^{*}$ mixing [4], as well as their relative contributions to the $Q$ rates $[7,8]$. While such complications presently preclude an $S U(3)$ analysis of $S-P S$ decays, there appears to be sufficient flexibility to accommodate the observations of table I.

To determine $g_{A}, g_{B}$, and $\theta_{Q}$, we have made least squares fits of the formulas in table III to the couplings of table II and $\gamma(\mathrm{B} \rightarrow \omega \pi)$. The results of these fits and their $\chi^{2}$ s are summarized in the lower half of table II. We note that $g_{B}$ and $\theta_{Q}$ are rather independent of which input data we use. This reflects the facts that $g_{B}$ is principally determined by the $B$ width and that $\theta_{Q} \approx 45^{\circ}$ corresponds to $Q_{1}$ decoupling from $K^{*} \pi$ and $Q_{2}$, from $\rho K$. The spread in values for $\mathrm{g}_{\mathrm{A}}$ stems from the differences in magnitudes of the partial widths from refs. [9] and [10]. With model uncertainties in mind, we take

$$
\begin{equation*}
\mathrm{g}_{\mathrm{A}}=+1.67 \pm .18 \mathrm{GeV}, \mathrm{~g}_{\mathrm{B}}=-.83 \pm .03 \mathrm{GeV}, \quad \theta_{\mathrm{Q}}=41^{\circ} \pm 4^{\circ} \tag{3}
\end{equation*}
$$

as conservative estimates for these $\mathrm{SU}(3)$ parameters. They are consistent with the parameters ${ }^{\dagger}$ which follow from the SU(3) constrained results of ref.[10]。

Restricting our attention to the parameters of eq。(3), we may graphically assess the $\operatorname{SU}(3)$ consistency of V-PS decays. For a given value of $\theta_{Q}$ (and $\theta_{V}$ ), the reduced couplings are linearly related to $g_{A}$ and $g_{B}$. Thus, in a plot of $g_{A}$ vs $\mathrm{g}_{\mathrm{B}}$, the observed couplings and their errors determine straight bands which must intersect at a common point $\left(\mathrm{g}_{\mathrm{A}}, \mathrm{g}_{\mathrm{B}}\right.$ ) for a consistent $\mathrm{SU}(3)$ description. From fig. 1 we see that the V-PS decays are in good agreement with $\operatorname{SU}(3)$ expectations, the only mild inconsistency possibly being in the coupling for $Q_{1} \rightarrow$ $\rho \mathrm{K}$. For $\theta_{\mathrm{Q}} \approx 45^{\circ}$ we expect (table III) the ratio $\Gamma\left(\mathrm{Q}_{1} \rightarrow \rho \mathrm{~K}\right) / \Gamma\left(\mathrm{Q}_{2} \rightarrow \mathrm{~K}^{*} \pi\right.$ ) to equal that of the phase spaces for these decays $(\sim, 37)$. Note that this is essentially the ratio found (table 1) from the fit of ref. [10] constrained by $Q_{A}=Q_{B}$ mixing. Within the uncertainties of the models $[9,10,11]$ used, we conclude that the decay rates for $Q_{1}$ and $Q_{2}$ lie within the conservative limits of table I and that they are consistent with $\mathrm{SU}(3)$.

$$
\mathrm{f}_{\mathrm{A}}=1.76 \pm .05, \mathrm{~g}_{\mathrm{B}}=-.87 \pm .03, \theta_{\mathrm{Q}}=42^{\circ} \pm 1^{\circ}, \text { and } \chi^{2}=9.1
$$

Having established a range of possible values for $g_{A}, g_{B}$ ，and $\theta_{Q}$ ，we now discuss what inferences may be made regarding the $A_{1}$ ．For $1_{0} 0<\operatorname{M}\left(A_{1}\right)<1.6$ GeV ，we find the $A_{1}$ width to $\rho \pi\left(\Gamma=\frac{2}{3}\left\langle q_{\rho}, \mathrm{g}_{\mathrm{A}}^{2} / \mathrm{M}^{2}\left(\mathrm{~A}_{1}\right)\right)\right.$ to be large（ $>.3 \mathrm{GeV}$ ）． To determine the $A_{1}$ mass，we need an additional assumption．For the $A_{1}$ nonet，the $\mathrm{SU}(3)$ mass formula（with particle names for masses）is

$$
\begin{equation*}
A_{1}^{2}=4 Q_{A}^{2}-3\left(E^{2} \cos ^{2} \theta_{A}+D^{2} \sin ^{2} \theta_{A}\right) \tag{4}
\end{equation*}
$$

where we denote the $A_{1}$ nonet isosinglets by $D, E$ and their mixing angle by $\theta_{A}$ 。 From the $Q_{A}-Q_{B}$ mixing mass formula

$$
\begin{equation*}
Q_{A, B}^{2}=\frac{1}{2}\left(Q_{1}^{2}+Q_{2}^{2} \pm\left(Q_{1}^{2}-Q_{2}^{2}\right) \cos 2 \theta_{Q}\right) \tag{5}
\end{equation*}
$$

we find $Q_{A} \sim 1.34 \mathrm{GeV}$ ，roughly independent of which value of $\theta_{Q}$ in table II we use．We now assume that the $E$ and $D$ are indeed in the $A_{1}$ nonet．Using the only measurement［17，3］of the rate for $E \rightarrow K * \bar{K}\left(\Gamma={ }^{\prime} q_{K} * g_{A}^{2} \cos ^{2} \theta_{A} / M_{E}^{2}\right)$ ， we may estimate the E－D mixing angle，$\theta_{A}$ ．We find $72^{\circ}<\left|\theta_{A}\right|<77^{\circ}$ ，the spread reflecting the range in values for $\mathrm{g}_{\mathrm{A}}$ 。From eq。（4）we thus compute $\mathrm{A}_{1}$ $\sim 1.47 \mathrm{GeV}$ with a broad $\rho \pi$ width as summarized in table II．We note that three recent partial wave analyses［ $18,19,20$ ］of nondiffractively produced $3 \pi$ sys－ tems find a broad bump in the $\mathrm{J}^{\mathrm{P}}=1^{+}, \mathrm{I}=1$ wave at $\sim 1.5 \mathrm{GeV}$ ．The values of the corresponding cross sections are consistent with the expectations of pro－ duction mechanisms［21］for a broad $\mathrm{A}_{1}$ 。

We have summarized and combined the known information on $Q$ decays to obtain a complete set of partial widths for $Q_{1}(1290)$ and $Q_{2}(1400)$ ．In addition we have given a conservative estimate of these rates and their errors to reflect the model－dependent assumptions［9，10］needed to determine the total widths of $Q_{1}$ and $Q_{2}$ ．From this information we determined the range of $\mathrm{SU}(3)$ param－ eters which characterize the V－PS decays of axial vector mesons．These
parameters and the assumption that the $D$ and $E$ mesons have $J^{P C}=1^{++}$lead to the prediction that the elusive $\mathrm{A}_{1}$ has a broad $\rho \pi$ width and a mass of $\sim 1.47$ GeV ．As such a mass yields a curious inverted level structure for the $\mathrm{A}_{1}$ nonet $\left(M\left(A_{1}\right)>M\left(Q_{A}\right)\right)$ ，it is clear that the spin of the $E$ and the $3 \pi$ bumps［18， $19,20]$ at $\sim 1.5 \mathrm{GeV}$ deserve further study．The $A_{1}$ issue aside，we conclude that the observed $Q_{1}(1290)$ and $Q_{2}(1400)$ decay rates can be reasonably de－ scribed within the context of $\operatorname{SU}(3)$ ．

| :---: | :---: | :---: | :---: | :---: |
| $Q_{1} \rightarrow K^{*} \pi$ | $2 \pm 2$ | $21 \pm 2$ | $12 \pm 13$ | $13 \pm 1$ |
| $\rightarrow \rho K$ | $75 \pm 6$ | $125 \pm 8$ | $100 \pm 35$ | $83 \pm 6$ |
| $\rightarrow \omega K^{(c)}$ | $24 \pm 3$ | $40 \pm 5$ | $32 \pm 11$ | $27 \pm 3$ |
| $\rightarrow K \pi$ | $26 \pm 6$ | $44 \pm 10$ | $35 \pm 13$ | $29 \pm 7$ |
| $-\epsilon K$ | $22 \pm 5$ | $36 \pm 8$ | $29 \pm 10$ | $24 \pm 5$ |
| $Q_{2} \rightarrow K * \pi$ | $117 \pm 10$ | $191 \pm 19$ | $154 \pm 52$ | $239 \pm 23$ |
| $-\rho K$ | $2 \pm 1$ | $2 \pm 1$ | $2 \pm 1$ | $1 \pm 1$ |
| $-\omega K$ | $\sim 0$ | $\sim 0$ | $\sim 0$ | $\sim 0$ |
| $-K \pi$ | $\sim 0$ | $\sim 0$ | $\sim 0$ | $\sim 0$ |
| $-\epsilon K$ | $23 \pm 12$ | $38 \pm 19$ | $31 \pm 11$ | $48 \pm 24$ |

(a) Possible $k \eta$ mode neglected; it could be as large as $\epsilon K$ and would reduce all numbers by a few percent.
(b) SU(3) refers only to the assumption that $Q_{A}$ and $Q_{B}$ mix; the errors are our estimates.
(c) Maximum $\omega \mathrm{K}$ width; see text.

TABLE II. S-wave couplings (GeV) for vector-pseudoscalar decays of $Q_{1}, Q_{2}$ and resulting $S U(3)$ parameters.

|  | Ref. 9 | Ref. 10 <br> No $\operatorname{SU}(3)$ | Mean ${ }^{(a)}$ |
| :---: | :---: | :---: | :---: |
| $\gamma\left(Q_{1}-K * \pi\right)$ | $.11 \pm .05$ | $.34 \pm .02$ | $.26 \pm .14$ |
| $\gamma\left(Q_{1}-\rho K\right)$ | $1.02 \pm .04$ | $1.32 \pm .04$ | $1.18 \pm .21$ |
| $\gamma\left(Q_{1}-\omega K\right)^{(b)}$ | $-.47 \pm .08$ | -. $61 \pm .11$ | $-.54 \pm .13$ |
| $\gamma\left(\mathrm{Q}_{2}-\mathrm{K}^{*} \pi\right)$ | $-.78 \pm .03$ | -. $99 \pm .05$ | $-.89 \pm .15$ |
| $\gamma\left(Q_{2}-\rho K\right)$ | -. $13 \pm .03$ | $-.13 \pm .03$ | -. $13 \pm .03$ |
| $\mathrm{g}_{\mathrm{A}}(\mathrm{GeV})$ | $1.40 \pm .06$ | $1.95 \pm .04$ | $1.67 \pm .18$ |
| $\mathrm{g}_{\mathrm{B}}(\mathrm{GeV})$ | -. $80 \pm .03$ | $-.90 \pm .02$ | $-.83 \pm .03$ |
| ${ }^{*} Q^{2}$ | $45^{\circ} \pm 2^{\circ}$ | $40^{\circ} \pm 1^{\circ}$ | $41^{\circ} \pm 4^{\circ}$ |
| $\chi^{2}$ | 25.1 | 32.0 | 1.3 |
| $\mathrm{M}_{\mathbf{A}_{1}}(\mathrm{GeV})^{(\mathrm{c})}$ | 1.47 | 1.46 | 1.47 |
| $\Gamma_{A_{1} \rightarrow \rho \pi}(\mathrm{GeV})$ | . 32 | . 60 | . 45 |

(a) Values correspond to mean widths and errors in Table 1.
(b) With $\gamma^{2}\left(Q_{1} \rightarrow \omega K\right)=(.22 \pm .07) \gamma^{2}\left(Q_{1} \rightarrow \rho K\right)$.
(c) Assumes both the $D$ and $E$ have $J^{P C}=1^{+}$.

TABLE III. Relation of the couplings $\gamma(\mathrm{Q} \rightarrow \mathrm{V}-\mathrm{PS})$ to the S-wave, $\mathrm{SU}(3) \mathrm{V}-\mathrm{PS}$ couplings $\left(g_{A}, g_{B}, g_{1}\right)$, the $Q_{A}-Q_{B}$ mixing angle $\left(\theta_{Q}\right)$, and the $\omega-\phi$ mixing angle ( $\theta_{\mathrm{V}}$ ).

| Mode | $Q_{1}$ | $Q_{2}$ |
| :--- | :--- | :--- |
| $K^{* \pi}$ | ${ }^{\frac{1}{2} g_{A} \cos \theta_{Q}}+\frac{3}{\sqrt{20}} g_{B} \sin \theta_{Q}$ | $-\frac{1}{2} g_{A} \sin \theta_{Q}+\frac{3}{\sqrt{20}} g_{B} \cos \theta_{Q}$ |
| $\rho K$ | $\frac{1}{2} g_{A} \cos \theta_{Q}-\frac{3}{\sqrt{20}} g_{B} \sin \theta_{Q}$ | $-\frac{1}{2} g_{A} \sin \theta_{Q}-\frac{3}{\sqrt{20}} g_{B} \cos \theta_{Q}$ |
|  | ${ }^{\frac{1}{2} g_{A} \cos \theta_{Q} \sin \theta_{V}}$ | $-\frac{1}{2} g_{A} \sin \theta_{Q} \sin \theta_{V}$ |
| $\omega K$ | $+\left(\frac{1}{\sqrt{20}} g_{B} \sin \theta_{V}+g_{I} \cos \theta_{V}\right) \sin \theta_{Q}$ | $+\left(\frac{1}{\sqrt{20}} g_{B} \sin \theta_{V}+g_{1} \cos \theta_{V}\right) \cos \theta_{Q}$ |

[^1]:    $\dagger$ We refer to each nonet by its isovector member：$\delta\left(\mathrm{J}^{\mathrm{PC}}=0^{++}\right), \mathrm{A}_{1}\left(\mathrm{~J}^{\mathrm{PC}}=\right.$ $\left.1^{++}\right), A_{2}\left(\mathrm{~J}^{\mathrm{PC}}=2^{++}\right), \mathrm{B}\left(\mathrm{J}^{\mathrm{PC}}=1^{+-}\right)$。
    $\dagger \dagger$ Both $\mathrm{J}^{\mathrm{PC}}=0^{-+}$and $1^{++}$remain possibilities for the E；see ref．［3］。The pseudoscalar assignment is attractive from the four quark point of view；see ref．［6］．
    $\dagger \dagger \dagger$ In addition to ourselves，Bowler（ref．［10］）and Basdevant and Berger（ref． ［11］）have considered models with only one Q resonance present．From the results of these studies，we conclude at the present time that a one－reso－ nance model cannot provide a quantitative description of the measurements．
