# FERMION FIELD THEORY ON A LATTICE: VARIA TIONAL ANALYSIS OF THE THIRRING MODEL* 

Sidney D. Drell, Benjamin Svetitsky**, and Marvin Weinstein Stanford Linear Accelerator Center Stanford University, Stanford, California 94305

#### Abstract

We extend variational techniques previously described to study the two-dimensional massless free fermion field and the Thirring model on a spatial lattice. The iterative block spin procedure of constructing an effective lattice Hamiltonian, starting by dissecting the lattice into 3-site blocks, is shown to be successful in producing results known for the continuum Thirring model.

Submitted to Phys. Rev.

[^0]
## I. INTRODUCTION

In this paper we continue the development and application of techni ques for finding the ground state and spectrum of low-lying physical states of field theories without recourse to either weak or strong coupling expansions. Following our earlier papers ${ }^{1}$ we study lattice Hamiltonians by means of a constructive variational procedure. The methods, which in our preceding paper (Paper III) were described and applied to free field theory of bosons in one space dimension and to the one-dimensional Ising model with a transverse applied magnetic field, are now applied to two fermion theories in $1 \mathrm{x}-1 \mathrm{t}$ dimensions: massless free 2-5 fermions and the Thirring model. Our aim in this paper is to demonstrate that these methods are easily applied to fermion theories and that our simple constructive approach reproduces results known to hold in soluble continuum models. Our fundamental approach to the study of these models is the same as in Paper III. Namely, we dissect the lattice into blocks containing a few sites which are coupled together via the gradient terms in the Hamiltonian. The Hamiltonian for the resulting few-degree of freedom problem is diagonalized and the degrees of freedom "thinned" by keeping only an appropriate set of low-lying states. We then construct an effective Hamiltonian by computing the matrix elements of the original Hamiltonian in the space of states spanned by the lowest energy eigenstates in each block. The process is then repeated for our new effective Hamiltonian. At each step, the coupling parameters of the effective Hamiltonian change and the procedure is repeated until we enter either a very weak or very strong coupling regime.

The specific features of these models which make them interesting are that (i) for the first time one must study the behavior of the first order gradient term which we introduced for fermion theories ${ }^{6}$ in order to avoid doubling of
states and preserve chiral symmetry, and (ii) the wave function renormalization, $\mathrm{Z}_{2}$, in the Thirring model vanishes when the coupling strength exceeds a finite value $\mathrm{g}_{\mathrm{cr}} \simeq 1.1$, even in the presence of a cutoff. We also analyze the lattice theory's Schwinger term and establish correspondence with the continuum theory.

As we show, our general procedure leads to the conclusion that there is a finite value of the coupling strength $\mathrm{g}_{\mathrm{cr}}$ such that for $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$ one only needs to study the general properties of the massless fermion theory. On the other hand, for $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}$, we are driven to study the theory of the Heisenberg anti-ferromagnet, which is also a theory with massless low lying excitations. In particular this analysis confirms a conjecture made in Paper II to the effect that the spectrum of the strong coupling limit of our lattice Thirring model is that of the Heisenberg anti-ferromagnet with nearest neighbor interactions even though the gradient appropriate to a fermion theory on the lattice includes long range couplings. In addition to these results we show in the appendix that the operator expression for the Schwinger term becomes, in the infinite volume limit, the ground state expectation value of the kinetic energy density divided by the square of the wave function renormalization constant $\mathrm{Z}_{2}(\mathrm{~g})$ 。

## II. GENERAL METHOD APPLIED TO FREE FIELD THEORY

To fix notation and illustrate our general method as well as its accuracy, we construct the ground state and lowest lying excited states of a lattice free fermion theory. The free massless lattice Hamiltonian is (see (3.1)-(3.4) of Paper II)

$$
\begin{equation*}
H=\Lambda \sum_{j_{1}, j_{2}} i \delta^{\prime}\left(j_{1}-j_{2}\right)\left(b_{j_{1}}^{+} b_{j_{2}}-d_{j_{1}}^{+} d_{j_{2}}\right) \tag{2,1}
\end{equation*}
$$

where

$$
\delta^{\prime}(\mathrm{j})=\left\{\begin{array}{cc}
\frac{-(-)^{j}}{\mathrm{j}} & \mathrm{j} \neq 0 \\
0 & \mathrm{j}=0
\end{array}\right.
$$

The two-component dimensionless lattice field $\chi_{j}$ is specified in the Dirac basis $_{-} \chi_{j}=\binom{b_{j}}{d_{j}^{+}} \quad$ with $\alpha=\gamma_{5}=\sigma_{3},{ }^{7}$ and satisfies the anti-commutation re-
lations

$$
\begin{array}{ll}
\left\{x_{j}^{+},\right. & \left.x_{j}\right\}=\delta_{j j^{\prime}} \mathbb{1} \\
\left\{x_{j},\right. & \left.x_{j^{\prime}}\right\}=0
\end{array}
$$

and so,

$$
\begin{align*}
& \left\{b_{j}, \quad b_{j}^{+}\right\}=\left\{d_{j}, d_{j}^{+}\right\}=\delta_{j} j^{\prime}  \tag{2,2}\\
& \left\{b_{j}, \quad d_{j}\right\}=0, \text { etc. }
\end{align*}
$$

$\Lambda$ is the inverse lattice spacing and the lattice has $2 N+1=\Lambda L$ sites.
This theory possesses two conserved "charges" which in this representation are

$$
\begin{align*}
& Q \equiv \sum_{j}: \chi_{j}^{+} \chi_{j}:=\sum_{j} Q_{j}=\sum_{j}\left(n_{b}(j)-n_{d}(j)\right) \\
& Q_{5} \equiv \sum_{j} \chi_{j}^{+} \gamma_{5} \chi_{j}=\sum_{j} Q_{5 j}=\sum_{j}\left(n_{b}(j)+n_{d}(j)-1\right) \tag{2.3}
\end{align*}
$$

where

$$
\begin{aligned}
& n_{b}(j)=b_{j}^{+} b_{j} \\
& n_{d}(j)=d_{j}^{+} d_{j}
\end{aligned}
$$

The Hamiltonian (2.1) is also invariant under three discrete symmetry operations. Two are unitary, and analogous to P and C , and one is anti-unitary corresponding to time reversal $\Theta$. We define them as follows:
(1) Charge conjugation

$$
\begin{array}{ll}
\mathrm{Cb}_{\mathrm{j}} \mathrm{C}^{-1}=\mathrm{b}_{\mathrm{j}}^{+} & \mathrm{CQC} \mathrm{C}^{-1}=-\mathrm{Q} \\
\mathrm{Cd}_{\mathrm{j}} \mathrm{C}^{-1}=\mathrm{d}_{\mathrm{j}}^{+} & \mathrm{CQ}_{5} \mathrm{C}^{-1}=-\mathrm{Q}_{5} \\
\mathrm{C}^{2}=1 & \tag{2.4}
\end{array}
$$

(2) Parity

$$
\begin{array}{ll}
P_{j} P^{-1}=d_{-j}^{+} & P Q P^{-1}=Q \\
\operatorname{Pd}_{j} P^{-1}=b_{-j}^{+} & P Q_{5} P^{-1}=-Q_{5}  \tag{2,5}\\
P^{2}=1 &
\end{array}
$$

(3) Time reversal
$\Theta=\mathrm{TK}$, where K is the anti-linear operator of complex conjugation and the unitary T operator is defined by

$$
\begin{array}{ll}
T b_{j} T^{-1}=d_{j} & \Theta Q \Theta^{-1}=-Q \\
T d_{j} T^{-1}=b_{j} & \Theta Q_{5} \Theta^{-1}=Q_{5} \\
\Theta^{2}=1 & \tag{2.6}
\end{array}
$$

Note that this problem shares one feature in common with the Ising calculation: there are only a finite number of states associated with each lattice site. In this case for each lattice site there are four basis states, summarized in Table I.

The transformation properties of these states under $P, C$, and $\Theta$ are given once we adopt the conventions
and

$$
\begin{align*}
& C\left|0_{j}\right\rangle=i\left| \pm{ }_{j}\right\rangle \\
& P\left|0_{j}\right\rangle=\left| \pm{ }_{j}\right\rangle \\
& \Theta\left|0_{j}\right\rangle=\left|0_{j}\right\rangle \tag{2.7}
\end{align*}
$$

Note that these conventions imply

$$
\begin{aligned}
& P\left|+_{j}\right\rangle=-\left|+_{j}\right\rangle \\
& P|-j\rangle=\left|--_{j}\right\rangle
\end{aligned}
$$

Also, it follows from Eq. (2.7) that

$$
C\left|+_{j}\right\rangle=i|-j\rangle
$$

In particular, fermions and antifermions have opposite intrinsic parity as usual.
Our purpose in this section is to study the free fermion model in order to establish the notation and methods to be used in the discussion of the Thirring model. For this reason, the calculation will be done in a way which is more cumbersome than it needs to be for this simple case. Aside from matters of notation, we will illustrate the fact that although $\delta^{\prime}\left(j_{1}-j_{2}\right)$ is non-vanishing for all $\mathrm{j}_{1} \neq \mathrm{j}_{2}$, it is not more difficult to work with than a gradient term expressed simply as the difference of fields at neighboring sites.

To begin our iterative procedure, we dissect the lattice into 3 -site blocks. We write

$$
\begin{align*}
\mathrm{H}= & \sum_{\mathrm{p}} \mathrm{H}_{\mathrm{p}}+\sum_{\mathrm{p}^{\prime} \neq \mathrm{p}} \mathrm{H}_{\mathrm{p} \mathrm{p}^{\prime}} \\
= & \Lambda \sum_{\mathrm{p}}\left[\sum_{\alpha \alpha^{\prime}} \mathrm{i} \delta^{\prime}\left(\alpha-\alpha^{\prime}\right)\left(\mathrm{b}_{\mathrm{p} \alpha}^{+} \mathrm{b}_{\mathrm{p} \alpha^{\prime}}-\mathrm{d}_{\mathrm{p} \alpha}^{+} \mathrm{d}_{\mathrm{p} \alpha^{\prime}}\right)\right]  \tag{2.8}\\
& +\Lambda \sum_{\mathrm{p} \neq \mathrm{p}^{\prime}}\left[\sum_{\alpha \alpha^{\prime}} \mathrm{i} \delta^{\prime}\left(3\left(\mathrm{p}-\mathrm{p}^{\prime}\right)+\alpha-\alpha^{\prime}\right)\left(\mathrm{b}_{\mathrm{p} \alpha}^{+} \mathrm{b}_{\mathrm{p}^{\prime} \alpha^{\prime}}-\mathrm{d}_{\mathrm{p} \alpha^{\prime}}^{+} \mathrm{d}_{\mathrm{p}^{\prime} \alpha^{\prime}}\right)\right]
\end{align*}
$$

where now p specifies the block and $\alpha=-1,0,1$ to specify a site within a block. Each single-block $H_{p}$ operates only on that factor of the product basis
which pertains to block p ，and is diagonal otherwise．
We choose to use three－site rather than two－site blocks when dealing with fermions so that the lowest eigenstates of the block Hamiltonian will have the same quantum numbers for $Q$ and $Q_{5}$ that are displayed for single sites in Table I，as will be clear immediately。 Our simple algorithm for＂thinning＂our space of states will be to first solve the $4^{3}=64$ degree of freedom problem， which can be done very simply by grouping the states in the different $\left(Q, Q_{5}\right)$ sectors which do not mix．We anticipate that the block states of lowest energy will be in the $\left(Q=0 ; Q_{5}=-1,+1\right)$ sectors，degenerate by $C$ symmetry，and we name them $\left|0_{p}\right\rangle$ and $\left| \pm_{p}\right\rangle$ ，respectively，in analogy with the single－site states of like quantum numbers．（That these are indeed the lowest block eigen－ states is verified in all cases by explicit computation。）However，when we apply $\mathrm{H}_{\mathrm{pp}}{ }^{\text {，between two blocks，it is apparent that it has no matrix element between }}$ $\left|0_{p}\right\rangle$ and $\left| \pm_{p}\right\rangle$ ；the charge－selection rule governing $b_{j}$ and $d_{j}$ indicates that we have to keep $\left(Q=+1,-1 ; Q_{5}=0\right)$ states in order to have non－zero block－ block coupling．We call these $\left|+_{p}\right\rangle$ and $\left|-_{p}\right\rangle$ ；again，they are degenerate。 Since these four sectors are the sectors of greatest degeneracy，they are gen－ erally those containing the lowest eigenlevels for the three－site problem．

To be specific，let us consider the 20 states in the $Q=0$ sector of the three－ site problem．These are listed in Table II along with the states into which they transform under iCP（note（iCP）${ }^{2}=1$ ）．The notation used is an obvious gener－ alization of that in Table I：the creation operators appear in an order from left to right corresponding to the ordering of the sites in the lattice，and at each site the $b_{j}^{+}$is to the left of $d_{j}^{+}$；thus for the block $p$

$$
\begin{equation*}
1- \pm+\rangle_{p} \equiv d_{3 p-1}^{+} b_{3 p}^{+} d_{3 p}^{+} b_{3 p+1}^{+}|000\rangle_{p} \tag{2.9}
\end{equation*}
$$

Under $C, P$ ，and $\Theta$ these states will have transformation properties de－ rived from（2．7）；viz．，starting from the $\left(Q=0, Q_{5}=-3\right)$ sector，

$$
\begin{align*}
& \text { C }|000\rangle_{p}=-i| \pm \pm \pm\rangle_{p} \\
& P \quad|000\rangle_{p}=| \pm \pm \pm\rangle_{p} \\
& \Theta \quad|000\rangle_{p}=|000\rangle_{p} \tag{2.10}
\end{align*}
$$

As a general rule，the overall phases to be introduced in the $\left(Q=0, Q_{5}= \pm I\right)$ and $\left(Q= \pm 1, Q_{5}=0\right)$ sectors as we proceed will be such that the phase convention（2．7）will hold for the lowest－lying block states（with $\left|0_{j}\right\rangle$ replaced by $\left.10_{\mathrm{p}}\right\rangle$ ，etc．）。We do this because we wish to identify the new block states in these sections with the original single site ones so that the only thing changing in the iteration is the Hamiltonian itself．

Of the nine states in the $Q_{5}=-1$ sector，six combinations that are even under iCP and three that are odd can be formed．The lowest eigenstate of the three－ site Hamiltonian is even and can be written as follows：

$$
\begin{align*}
\left|0_{\mathrm{p}}\right\rangle= & \frac{1}{18}(3-4 \mathrm{i})|+0\rangle_{\mathrm{p}}+\frac{1}{18}(3+4 \mathrm{i})|-0+\rangle_{\mathrm{p}} \\
& \left.-\frac{1}{9}(3+\mathrm{i})[1+-0\rangle+|0+-\rangle\right]_{\mathrm{p}}-\frac{1}{9}(3-\mathrm{i})[|0-+\rangle+|-+0\rangle]_{\mathrm{p}} \\
& +\frac{4}{9} \mathrm{i}\left[|0 \pm 0\rangle+\frac{5}{8}(| \pm 00\rangle+|00 \pm\rangle\rangle\right]_{\mathrm{p}}  \tag{2.11}\\
\mathrm{H}_{\mathrm{p}}\left|0_{\mathrm{p}}\right\rangle= & -3 \Lambda\left|0_{\mathrm{p}}\right\rangle
\end{align*}
$$

The other eight eigenstates in the $\left(Q=0, Q_{5}=-1\right)$ sector lie higher in energy with eigenvalues $+3 \Lambda,+3 / 2 \Lambda,+3 / 2 \Lambda, 0,0,0,-3 / 2 \Lambda,-3 / 2 \Lambda$ 。 Since the state having $\left(Q=0, Q_{5}=-3\right)$ is unique，it must be an eigenstate of $H_{p}$ and it is clearly a null eigenstate。

The $Q=1$ sector has the 15 basis states listed in Table III along with their
corresponding $P$ transforms ( $C$ takes us from the $Q=1$ to the $Q=-1$ sector and is not important in this context).

The lowest eigenstate of $H_{p}$ in the $\mathrm{Q}=1$ sector is formed from the six odd eigenstates of $P$ in the $Q_{5}=0$ sector; this corresponds to the odd parity of the single site eigenstate according to (2.7). It is given by: ${ }^{8}$

$$
\begin{align*}
\left|+_{p}\right\rangle= & \frac{1}{18}(4-3 i)| \pm+0\rangle_{p}-\frac{1}{18}(4+3 i)|0+ \pm\rangle_{p} \\
& \left.+\frac{1}{9}(1-3 i)[1+0 \pm\rangle+|0 \pm+\rangle\right]_{p}-\frac{1}{9}(1+3 i)[| \pm 0+\rangle+\mid + \pm 0]_{p} \\
& \left.\left.+\frac{4}{9}[1+-+\rangle+\frac{5}{8}(1++-\rangle+|-++\rangle\right)\right]_{p}  \tag{2,12}\\
H_{p}\left|+_{p}\right\rangle= & -3 \Lambda\left|+_{p}\right\rangle
\end{align*}
$$

The states specified in $(2.11)$ and $(2,12)$ plus their two charge conjugate counterparts $\left| \pm{ }_{p}\right\rangle$ and $\left|-_{p}\right\rangle$ are the states used as a basis in which to construct the truncated Hamiltonian. This same process is then repeated by combining 3 neighboring 3 -site blocks as illustrated in Fig。1. In order to do this, however, we must express the terms in $H_{p p}$ ( that couple different blocks to one another) in terms of creation and annihilation operators, $B_{p}^{+}, B_{p}$ and $D_{p}^{+}, D_{p}$, defined by

$$
\begin{align*}
& B_{p}\left|0_{p}\right\rangle=D_{p}\left|0_{p}\right\rangle=0  \tag{2,13}\\
& B_{p}^{+}\left|0_{p}\right\rangle=\left|+_{p}\right\rangle \\
& D_{p}^{+}\left|0_{p}\right\rangle=\left|-{ }_{p}\right\rangle \\
& B_{p}^{+} D_{p}^{+}\left|0_{p}\right\rangle=\left| \pm_{p}\right\rangle \\
& \left\{B_{p}^{+}, B_{p^{\prime}}\right\}=\delta_{p}, \quad \text { etc. }
\end{align*}
$$

To accomplish this let us define for site $\alpha=-1,0,1$ in the $\mathrm{p}^{\text {th }}$ block,

$$
\begin{align*}
& \left\langle+_{p}\right| b_{3 p+\alpha}^{+}\left|0_{p}\right\rangle \equiv u_{\alpha}  \tag{2,14}\\
& \langle-p| d_{3 p+\alpha}^{+}\left|0_{p}\right\rangle \equiv v_{\alpha}
\end{align*}
$$

It then follows from the symmetries $(2,4)-(2,6)$ that we can fix the remaining matrix elements: e.g., from (2.4) and (2.7) we see that

$$
\begin{align*}
\left\langle \pm_{p}\right| b_{3 p+\alpha}^{+}\left|-{ }_{p}\right\rangle & =\left\langle-_{p}\right| b_{3 p+\alpha}\left| \pm_{p}\right\rangle^{*} \\
& =\left\langle+_{p}\right| C b_{3 p+\alpha} C\left|0_{p}\right\rangle^{*} \\
& =\left\langle+_{p}^{+}\right| b_{3 p+\alpha}^{+}\left|0_{p}\right\rangle^{*} \\
& =u_{\alpha}^{*} \tag{2.15}
\end{align*}
$$

From (2.5), we find that

$$
\begin{equation*}
u_{\alpha}=v_{-\alpha} \tag{2.16}
\end{equation*}
$$

and from (2.6)

$$
\begin{equation*}
u_{\alpha}=u_{-\alpha}^{*} \tag{2,17}
\end{equation*}
$$

Combining these results, we see that we can write truncated operators

$$
\begin{align*}
& \left(\mathrm{b}_{3 \mathrm{p}+\alpha}^{+}\right)^{\mathrm{TR}} \equiv \mathrm{~B}_{\mathrm{p}}^{+}\left\{\mathrm{u}_{\alpha} \mathrm{Q}_{5 \mathrm{p}}^{2}+\mathrm{u}_{\alpha}^{*} \mathrm{Q}_{\mathrm{p}}^{2}\right\}  \tag{2.18}\\
& \left(\mathrm{d}_{3 \mathrm{p}+\alpha}^{+}\right)^{\mathrm{TR}} \equiv \mathrm{D}_{\mathrm{p}}^{+}\left\{\mathrm{v}_{\alpha} \mathrm{Q}_{5 \mathrm{p}}^{2}+\mathrm{v}_{\alpha}^{*} \mathrm{Q}_{\mathrm{p}}^{2}\right\}
\end{align*}
$$

where

$$
\begin{aligned}
Q_{p} & \equiv B_{p}^{+} B_{p}-D_{p}^{+} D_{p} \\
Q_{5 p} & \equiv B_{p}^{+} B_{p}+D_{p}^{+} D_{p}-1
\end{aligned}
$$

Equations $(2,18)$ summarize, in operator form, the contents of $(2,13)-(2,17)$ and allow us to write the Hamiltonian restricted to the Hilbert space spanned by tensor products of the four basis vectors $\left|0_{p}\right\rangle,\left| \pm_{p}\right\rangle,\left|+_{p}\right\rangle$, and $\left|-_{\mathrm{p}}\right\rangle$. Since in this subspace

$$
\begin{equation*}
Q_{p}^{2}+Q_{5 p}^{2}=1 \tag{2.19}
\end{equation*}
$$

it follows that if $u_{\alpha}$ and $v_{\alpha}$ are real, then our truncation procedure amounts to making the simple substitutions

$$
\begin{align*}
& \left(\mathrm{b}_{3 \mathrm{p}+\alpha}^{+}\right)^{\mathrm{TR}}=\mathrm{u}_{\alpha} \mathrm{B}_{\mathrm{p}}^{+} \\
& \left(\mathrm{d}_{3 \mathrm{p}+\alpha}^{+}\right)^{\mathrm{TR}}=u_{\alpha} \mathrm{D}_{\mathrm{p}}^{+} \tag{2.20}
\end{align*}
$$

For the present case of a free fermion model $u_{\alpha}$ and $v_{\alpha}$ are real。 ${ }^{9}$ However, this is not generally true, and the transformation (2.18) for the Thirring model takes the more general form as we shall sec in the next section. Restricting to the free field case and collecting our results, the truncated Hamiltonian (2.1) becomes

$$
\begin{align*}
\mathrm{H}_{(1)}^{\mathrm{TR}}=-(3 \Lambda) \frac{\Lambda L}{3}+ & \sum_{\mathrm{p} \neq \mathrm{q}} \mathrm{i}\left(\sum_{\alpha, \beta=-1}^{+1} \delta^{\prime}(3(\mathrm{p}-\mathrm{q})+\alpha-\beta) \mathrm{u}_{\alpha} \mathrm{u}_{\beta}\right)  \tag{2.21}\\
& \times\left[\mathrm{B}_{\mathrm{p}}^{+} \mathrm{B}_{\mathrm{q}}-\mathrm{D}_{\mathrm{p}}^{+} \mathrm{D}_{\mathrm{q}}\right]
\end{align*}
$$

where $H_{(1)}^{T R}$ denotes the Hamiltonian obtained after the first iteration. Proceeding to the second iteration, we couple three adjacent "sites" of the new Hamiltonian (or blocks of the original Hamiltonian) and again retain the lowest eigenstate in each of the four sectors $\left(Q= \pm 1, Q_{5}=0\right)$ and $\left(Q=0, Q_{5}= \pm 1\right)$ 。

Of course, this time the gradient is given in terms of a new function

$$
\begin{equation*}
\Delta_{1}(p-q) \equiv \sum_{\alpha, \beta=-1}^{+1} \delta^{\prime}(3(p-q)+\alpha-\beta) u_{\alpha} u_{\beta} \tag{2.22}
\end{equation*}
$$

which is readily calculated using (2.11) - (2.14) and the definition (2.1) of $\delta^{\prime}(\mathrm{j})$.

Table IV compares the first few terms of $\delta^{\prime}(\mathbf{j})$ to $\Delta_{1}(\mathbf{j})$. It is evident from the table that in a single iteration, the strength of the gradient is decreased by almost a factor of two and the second nearest neighbor term is suppressed by $\approx 30 \%$ relative to the nearest neighbor one. Continuing this process, we find that, aside from the fact that the gradient's overall scale keeps dropping by a factor $\approx 8 / 15, \Delta_{n}(\mathrm{j})$ rapidly converges to a fixed form. One can approximately carry out the iteration procedure analytically by setting $\Delta_{\mathrm{n}}(2) / \Delta_{\mathrm{n}}(1)=-1 / 2=\delta^{\prime}(2) / \delta^{\prime}(1)$, in order to estimate the ground state energy。 One obtains

$$
\begin{align*}
E & \approx-3 \Lambda \cdot \frac{\Lambda L}{3}-3 \Lambda\left(\frac{8}{15}\right) \frac{\Lambda \mathrm{L}}{3^{2}}-3 \Lambda\left(\frac{8}{15}\right)^{2} \frac{\Lambda \mathrm{~L}}{3}+\cdots \\
& =-\Lambda^{2} \mathrm{~L}\left(\frac{45}{37}\right) \simeq-1.216 \Lambda^{2} \mathrm{~L} \tag{2,23}
\end{align*}
$$

Carrying out the calculation exactly by means of a computer yields an almost identical result

$$
\begin{equation*}
\mathrm{E}_{0}^{\mathrm{TR}}=-1.217 \Lambda^{2} \mathrm{~L} \tag{2.24}
\end{equation*}
$$

The exact ground state energy can of course be computed very simply from (2.1)
by transforming to momentum space. This leads to the familiar expression

$$
\begin{equation*}
H=\sum_{k=-\pi \Lambda}^{+\pi \Lambda} k\left[n_{b}(k)-n_{d}(k)\right] \tag{2.25}
\end{equation*}
$$

where $n_{b}(k)$ and $n_{d}(k)$ are the number of particles and anti-particles, respectively, with momentum k 。 The ground state corresponds to filling all $\mathrm{k}>0$ states with $d$-quanta, $n_{d}(k)=\theta(+k)$, and all $k<0$ states with b-quanta, $n_{b}(k)=\theta(-k)$. Actually the ground state is 4-fold degenerate corresponding to whether $n_{b}(0)=0,1$ and $n_{d}(0)=0,1$ in the $k=0$ state $\left(n_{\circ} b_{\text {。 }}\right.$ in the infinite volume limit it becomes infinitely degenerate). It follows that the ground state energy for $(2.25)$ is

$$
\begin{equation*}
\mathrm{E}_{0}=-2 \sum_{0}^{\pi \Lambda} \mathrm{k}=-2 \frac{\mathrm{~L}}{2 \pi} \int_{0}^{\pi \Lambda} \mathrm{kdk}=-\frac{\pi}{2} \Lambda^{2} \mathrm{~L} \tag{2.26}
\end{equation*}
$$

Hence our simple truncation procedure leads to a ground state energy that lies $22 \%$ above the exact answer. There are two ways in which this agreement can be improved. One is by keeping a larger subspace of states than the four of the 64 retained in the above calculation for each three-site block. This has proved very effective in the study of the Ising model. Alternatively we can determine which states to retain by a variational procedure as illustrated in Paper III. ${ }^{10}$

## III. LATTICE THIRRING MODEL

Turning now to the Thirring model, we add a chirally invariant "potential term" to the Hamiltonian of the free fermion theory. The lattice Hamiltonian is (see Eq. $(2.15)$ and Section III-A of Paper II)

$$
\begin{align*}
\mathrm{H} & =\Lambda\left[\sum_{\mathrm{j}_{1} \mathrm{j}_{2}} \mathrm{i} \delta^{\prime}\left(\mathrm{j}_{1}-\mathrm{j}_{2}\right) \chi_{\mathrm{j}_{1}}^{+} \alpha \chi_{\mathrm{j}_{2}}-\frac{\mathrm{g}}{2} \sum_{\mathrm{j}}\left\{\left(\bar{\chi}_{\mathrm{j}} \chi_{\mathrm{j}}\right)^{2}-\left(\bar{\chi}_{\mathrm{j}} \gamma_{5} \chi_{\mathrm{j}}\right)^{2}\right\}\right]  \tag{3.1}\\
& =\Lambda\left[\sum_{\mathrm{j}, \mathrm{j}_{2}} \mathrm{i} \delta^{\prime}\left(\mathrm{j}_{1}-\mathrm{j}_{2}\right)\left(\mathrm{b}_{\mathrm{j}_{1}}^{+} \mathrm{b}_{\mathrm{j}_{2}}-\mathrm{d}_{\mathrm{j}_{1}}^{+} \mathrm{d}_{\mathrm{j}_{2}}\right)-\mathrm{g} \sum_{\mathrm{j}} Q_{5 \mathrm{j}}^{2}\right]
\end{align*}
$$

where $Q_{5 j}$ is defined by $(2,3) \ldots$. Since the added potential term commutes with $Q$ and $Q_{5}$, we again choose the site basis in Table I used for the massless free fermion theory. The discrete symmetries $C, P$, and $\Theta$ of $(2.4)-(2.7)$ are again useful for classifying states.

Proceeding as in Section II, we divide the lattice into blocks of three sites, and rewrite the Hamiltonian divided into single-block and block-block terms

$$
\begin{align*}
& \mathrm{H}=\sum_{\mathrm{p}} \mathrm{H}_{\mathrm{p}}+\sum_{\mathrm{p} \neq \mathrm{p}^{\prime}} \mathrm{H}_{\mathrm{pp}^{\prime}} \\
& =\Lambda \sum_{\mathrm{p}}\left[\sum_{\alpha}(-\mathrm{g}) \mathrm{Q}_{5 \mathrm{p} \alpha^{+}}^{2} \sum_{\alpha \alpha^{\prime}} \mathrm{i} \delta^{\prime}\left(\alpha-\alpha^{\prime}\right)\left(\mathrm{b}_{\mathrm{p} \alpha^{\mathrm{b}} \mathrm{p} \alpha^{\prime}}{ }^{-\mathrm{d}_{\mathrm{p} \alpha^{+}}^{+} \mathrm{p} \alpha^{\prime}}\right)\right] \\
& +\Lambda \sum_{p \neq p^{\prime}}\left[\sum_{\alpha \alpha^{\prime}} i \delta^{\prime}\left(3\left(p-p^{\prime}\right)+\alpha-\alpha^{\prime}\right)\left(b_{p \alpha^{\prime}}^{+} p_{p^{\prime} \alpha^{\prime}}-d_{p \alpha^{\prime}}^{+} d_{p^{\prime} \alpha^{\prime}}\right)\right] \tag{3.2}
\end{align*}
$$

The plan is again to diagonalize the single-block terms exactly, to truncate the Hilbert space to the lowest few eigenstates, and to rewrite the block-block coupling term in terms of operators which are confined to the truncated space.

The enumeration of block states and the block diagonalization of $H_{p}$ according to $Q$ and $Q_{5}$ go through as for the free field, and once more we choose the lowest eigenstates $\left|0_{p}\right\rangle,\left|+_{p}\right\rangle,\left|-{ }_{p}\right\rangle$, and $\left| \pm_{p}\right\rangle$ and define $B_{p}$ and $D_{p^{\circ}}$

Equations $(2,16)$ and $(2,17)$ still hold, because they depend only on the same symmetries (2.4)-(2.6). Furthermore, (2.18) is unchanged; indeed, when we truncate our block Hilbert space, that expression for ( $\mathrm{b}^{+}$) ${ }^{\mathrm{TR}}$ is the most general operator on the subspace with selection rules $\Delta \mathrm{Q}=+1, \Delta \mathrm{Q}_{5}=+1$; and analogously for $\left(\mathrm{d}^{+}\right)$TR 。However, we can no longer write $(2.20)$, because $u_{j}$ is no longer real. The reality condition depended on the symmetry of $H$ under $Q \leftrightarrow Q_{5}$, which does not hold for $\mathrm{g} \neq 0$ in (3.1). Unlike the free field case, now

$$
\left\langle+_{p}\right| b_{j}^{+}\left|0_{p}\right\rangle \neq\left\langle \pm_{p}\right| b_{j}^{+}|-p\rangle
$$

Thus (2.18) no longer turns into a simple scaling transformation for $\mathrm{b}^{+}$and $\mathrm{d}^{+}$。 Instead it expresses a non-linear Bogoliubov transformation which forces these operators to take on their most general forms in the next iteration.

The single site term $H_{p}$ in (3.2) becomes the sum of two terms: a constant representing an overall energy shift and a term proportional to $\left(Q_{5 p}\right)^{2}$, which splits the degenerate pairs $\left|+_{p}\right\rangle$ and $\left|-{ }_{p}\right\rangle$ from $\left|0_{p}\right\rangle$ and $\left| \pm_{p}\right\rangle$; viz.

$$
\begin{equation*}
\frac{\left(\mathrm{H}_{\mathrm{p}}\right)_{(1)}^{\mathrm{TR}}}{\Lambda}=\mathrm{E}_{1}-\mathrm{g}_{1} \mathrm{Q}_{5 \mathrm{p}}^{2} \tag{3.3}
\end{equation*}
$$

This is its most general form consistent with the symmetries. Correspondingly, the kinetic Hamiltonian turns into

$$
\begin{align*}
\frac{\left.\left(H_{p, p^{\prime}}\right)^{T 1}\right)}{\Lambda R}= & B_{p}^{+}\left[A\left(p-p^{\prime}\right) Q_{5 p}^{2} Q_{5 p^{\prime}}^{2}+B\left(p-p^{\prime}\right) Q_{p}^{2} Q_{5 p^{\prime}}^{2}\right. \\
& \left.-B^{*}\left(p-p^{\prime}\right) Q_{5 p}^{2} Q_{p^{\prime}}^{2}-A^{*}\left(p-p^{\prime}\right) Q_{p}^{2} Q_{p}^{2}\right] B_{p^{\prime}} \\
& -D_{p}^{+}\left[-A^{*}\left(p-p^{\prime}\right) Q_{5 p}^{2} Q_{5 p^{\prime}}^{2}+B\left(p-p^{\prime}\right) Q_{p}^{2} Q_{5 p^{\prime}}^{2}\right.  \tag{3.4}\\
& \left.-B^{*}\left(p-p^{\prime}\right) Q_{5 p}^{2} Q_{p^{\prime}}^{2}+A\left(p-p^{\prime}\right) Q_{p}^{2} Q_{p^{\prime}}^{2}\right] D_{p^{\prime}}
\end{align*}
$$

where

$$
\begin{align*}
& A\left(p-p^{\prime}\right)=\sum_{\alpha \alpha^{\prime}} i \delta^{\prime}\left(3\left(p-p^{\prime}\right)+\alpha-\alpha^{\prime}\right) u_{\alpha^{\prime}} u_{\alpha^{\prime}}^{*}  \tag{3.5}\\
& B\left(p-p^{\prime}\right)=\sum_{\alpha \alpha^{\prime}} i \delta^{\prime}\left(3\left(p-p^{\prime}\right)+\alpha-\alpha^{\prime}\right) u_{\alpha^{\prime}}^{*} u_{\alpha^{\prime}}^{*}
\end{align*}
$$

Note that if $u_{\alpha}=u_{\alpha}^{*}$, then $\mathrm{A}=\mathrm{B}$ and (3.4) reduces to (2.21) when we use (2.19). Equation (3.4) is in fact the most general site-site (or block-block) coupling Hamiltonian which conserves $Q, Q_{5}, C$, and $P$, for any functions $A$ and $B$ subject to

$$
\begin{equation*}
A(-p)=A^{*}(p) \quad B(-p)=-B(p) \tag{3.6}
\end{equation*}
$$

We are now faced with the prospect of iterating (that is, blocking and truncating) this operator as a kinetic energy term in the Hamiltonian. It is clear that the generality of (3.4) precludes any further change in form in the truncated subspace to which we have restricted ourselves.

In the second iteration, we treat our former blocks as "sites" and group them into (super)blocks as in the free field theory. After diagonalizing, we will need matrix elements such as (letting $\alpha$ index a "site" within "block" p)

$$
\left\langle+{ }_{p}\right| B_{3 p+\alpha}^{+} Q_{3 p+\alpha}^{2}\left|0_{p}\right\rangle \equiv r_{\alpha}
$$

and

$$
\left\langle+{ }_{p} \mid B_{3 p+\alpha}^{+} Q_{5,3 p+\alpha}^{2} 10_{p}\right\rangle \equiv w_{\alpha}
$$

Indeed, use of $C$ and $P$ symmetries shows these to be the only independent matrix elements. Then the newly truncated $H_{p p}$, takes the form (3.4) with new $A(p)$ and $B(p)$ given by a generalization of (3.5):

$$
\begin{align*}
& \mathrm{A}\left(\mathrm{p}-\mathrm{p}^{\prime}\right) \rightarrow \sum_{\alpha \alpha^{\prime}} \mathrm{A}(\mathrm{x}) \mathrm{r}_{\alpha^{\prime}} \mathrm{r}_{\alpha^{\prime}}^{*}-\mathrm{A}^{*}(\mathrm{x}) \mathrm{w}_{\alpha} \mathrm{w}_{\alpha^{\prime}}^{*}+\mathrm{B}(\mathrm{x}) \mathrm{w}_{\alpha^{\prime}} \mathrm{r}_{\alpha^{\prime}}^{*}-\mathrm{B}^{*}(\mathrm{x}) \mathrm{r}_{\alpha^{\prime}} \mathrm{w}_{\alpha^{\prime}}^{*}  \tag{3.8}\\
& \mathrm{~B}\left(\mathrm{p}-\mathrm{p}^{\prime}\right) \rightarrow \sum_{\alpha \alpha^{\prime}} \mathrm{B}(\mathrm{x}) \mathrm{r}_{\alpha^{*}} \mathrm{r}_{\alpha^{\prime}}^{*}-\mathrm{B}^{*}(\mathrm{x}) \mathrm{w}_{\alpha^{*}}^{*} \mathrm{w}_{\alpha^{\prime}}^{*}+\mathrm{A}(\mathrm{x}) \mathrm{w}_{\alpha^{*}} \mathrm{r}_{\alpha^{\prime}}^{*}-\mathrm{A}^{*}(\mathrm{x}) \mathrm{r}_{\alpha}^{*} \mathrm{w}_{\alpha^{\prime}}^{*}
\end{align*}
$$

where

$$
x=3\left(p-p^{\prime}\right)+\alpha-\alpha^{\prime}
$$

This procedure can in fact be specialized to the first iteration if we start with $\mathrm{A}(\mathrm{j})=\mathrm{B}(\mathrm{j})=\mathrm{i} \delta^{\prime}(\mathrm{j})$.

It is convenient, in order to make later comparison with the free-field case more transparent, to rewrite $H_{(n)}$ (defined as $H_{(n)}^{T R} / \Lambda$ in the $n^{\text {th }}$ iteration) as

$$
\begin{align*}
H_{(n)}= & \sum_{p_{1}, p_{2}} i X_{n}\left(p_{1}-p_{2}\right)\left(B_{p_{1}}^{+} B_{p_{2}}-D_{p_{1}}^{+} D_{p_{2}}\right) \\
& -g_{n} \sum_{p}\left(B_{p}^{+} B_{p}+D_{p}^{+} D_{p}-1\right)^{2}+E_{n} \\
& +\sum_{p_{1} p_{2}} i\left[Z_{n}\left(p_{1}-p_{2}\right)\left(B_{p_{1}}^{+} Q_{p_{1}}^{2} Q_{p_{2}}^{2} B_{p_{2}}-D_{p_{1}}^{+} Q_{5 p_{1}}^{2} Q_{5 p_{2}}^{2} D_{p_{2}}\right)\right. \\
& \left.+Z_{n}^{*}\left(p_{1}-p_{2}\right)\left(B_{p_{1}}^{+} Q_{5 p_{1}}^{2} Q_{5 p_{2}}^{2} B_{p_{2}}-D_{p_{1}}^{+} Q_{p_{1}}^{2} Q_{p_{2}}^{2} D_{p_{2}}\right)\right] \tag{3.9}
\end{align*}
$$

where $X_{n}(p)$ and $Z_{n}(p)$ are the appropriate linear combinations of $A^{\prime} s$ and $B^{\prime} s$ : viz., $i X_{n}(p) \equiv B_{n}(p)$ and $i Z_{n}(p)=B_{n}^{*}(p)-A_{n}^{*}(p)$ 。

In this way our Hamiltonian (3.2), with generalized kinetic term (3.4), takes on the same form when blocked and truncated, subject to an energy shift and a change in the value of $g$ and in the form of the "gradient functions" $A(j)$ and $\mathrm{B}(\mathrm{j})$. We iterate this procedure until one of three limits is reached:
(a) $X_{n}$ and $Z_{n} \rightarrow \infty$ relative to $g_{n}$. The resulting gradient functions must then be compared to those resulting from the free field (where $g=0$ to begin with). More on this later.
(b) $X_{n}$ and $Z_{n} \rightarrow 0$ relative to $g_{n}$ 。 This, the "strong coupling limit," 11 is the Heisenberg antiferromagnet as discussed in Paper II, and the limiting form of the gradient functions before they go to zero must be examined to determine the degeneracy-breaking of the ground state。
(c) $X_{n}$ and $Z_{n}$ approach a fixed form, and a fixed ratio with respect to $g_{n}$. In this case the dynamics at large scales remain complicated.

We have thus far applied our procedure of successively truncating the Hilbert space to compute the general form of the Hamiltonian. We may also apply this procedure to any other operator by computing its matrix elements between the states retained in each step of truncation. An example which will be useful for calculating the Schwinger term in the Appendix is the ground state expectation value of the potential energy density (in units of $\Lambda=(2 N+1) / L$ )

$$
\begin{align*}
\mathrm{V} & =\frac{1}{2 \mathrm{~N}+1} \sum_{j}-\mathrm{g} Q_{5 j}^{2} \\
& =\frac{3}{2 \mathrm{~N}+1} \sum_{\mathrm{p}}\left(\frac{1}{3} \sum_{\alpha=-1,0,1}(-\mathrm{g}) Q_{5,3 \mathrm{p}+\alpha}^{2}\right) \equiv \frac{3}{2 \mathrm{~N}+1} \sum_{\mathrm{p}} \mathrm{~V}_{\mathrm{p}} \tag{3.10}
\end{align*}
$$

Noting that $Q_{5 j}^{2}$ is diagonal in our truncated basis and that it commutes with C, we let, in a 3-site block basis,

$$
\begin{align*}
a+b & =-\frac{g}{3} \sum_{\alpha}\left\langle 0_{p} \mid Q_{5,3 p+\alpha}^{2} 10_{p}\right\rangle=\left\langle 0_{p}\right| V_{p}\left|0_{p}\right\rangle=\left\langle \pm_{p}\right| V_{p}\left| \pm_{p}\right\rangle  \tag{3.11}\\
a & =-\frac{g}{3} \sum_{\alpha}\left\langle+_{p}\right| Q_{5,3 p+\alpha}^{2}\left|+_{p}\right\rangle=\left\langle+_{p}\right| V_{p}\left|+_{p}\right\rangle=\left\langle-{ }_{p}\right| V\left|--_{p}\right\rangle
\end{align*}
$$

Then the matrix elements of $V_{p}$ in the truncated basis are summarized by writing

$$
V_{p}=a+b Q_{5 p}^{2}
$$

Since $\frac{2 N+1}{3}$ is just $N_{b}$, the number of blocks,

$$
\begin{equation*}
V=a+\frac{1}{N_{b}} \sum_{p} b Q_{5 p}^{2} \tag{3.12}
\end{equation*}
$$

This procedure may be repeated through following blockings, and the recursion formula is

$$
\begin{align*}
& \mathrm{a} \rightarrow \mathrm{a}+\frac{\mathrm{b}}{3} \sum_{\alpha}\left\langle+_{\mathrm{p}}\right| \mathrm{Q}_{5,3 \mathrm{p}+\alpha}^{2}\left|+_{\mathrm{p}}\right\rangle \\
& \left.\left.\mathrm{b} \rightarrow \frac{\mathrm{~b}}{3} \sum_{\alpha}{ }_{[ }{ }^{-} 0_{\mathrm{p}}\left|Q_{5,3 \mathrm{p}+\alpha}^{2}\right| 0_{\mathrm{p}}\right\rangle-\left\langle+_{\mathrm{p}}\right| Q_{5,3 p+\alpha}^{2}\left|+_{p}\right\rangle\right]  \tag{3.13}\\
& N_{\mathrm{b}} \rightarrow N_{\mathrm{b}} / 3
\end{align*}
$$

Initial conditions are $\mathrm{a}=0, \mathrm{~b}=-\mathrm{g}$.
Thus we may calculate $\langle V\rangle$ in any of our final variational states. Since we already know what the Hamiltonian is doing in the iteration, we also determine the kinetic energy density by this process. This will be of interest for determining the theory's Schwinger term.

In order to renormalize the field, we will need its amplitude to create a $\left(Q=1, Q_{5}=0\right)$ state at rest from the vacuum, i.e.,

$$
\begin{equation*}
\sqrt{\Lambda}\langle 0| \chi(\mathrm{k}=0)|+\rangle \equiv \sqrt{\frac{\Lambda}{2 \mathrm{~N}+1}}\langle 0| \sum_{\mathrm{j}} \chi_{\mathrm{j}}|+\rangle \equiv \sqrt{\Lambda} \mathrm{z}_{2}^{1 / 2}\binom{1}{0} \tag{3.14}
\end{equation*}
$$

The operator of interest in (3.14) is

$$
\begin{equation*}
\frac{1}{\sqrt{2 N+1}} \sum_{j} b_{j}=\sqrt{\frac{3}{2 N+1}} \sum_{p}\left(\frac{1}{\sqrt{3}} \sum_{\alpha} b_{3 p+\alpha}\right) \tag{3,15}
\end{equation*}
$$

after one blocking. The symmetries of the theory imply that in the truncated basis

$$
\begin{equation*}
\frac{1}{\sqrt{3}} \sum_{\alpha}\left(b_{3 p+\alpha}\right)^{\mathrm{TR}}=\zeta_{1} \mathrm{~B}_{\mathrm{p}} \tag{3.16}
\end{equation*}
$$

After n iterations, with $\mathrm{N}_{\mathrm{b}}=(2 \mathrm{~N}+1) / 3^{\mathrm{n}}$, we have

$$
\begin{equation*}
\frac{1}{\sqrt{2 N+1}}\left(\sum_{j} b_{j}\right)^{T R}=\frac{1}{\sqrt{N_{b}}} \zeta^{(n)} \sum_{p} B_{p} \tag{3.17}
\end{equation*}
$$

where

$$
\zeta^{(n)}=\prod_{i=1}^{n} \zeta_{i}
$$

At this stage there is no order in the system on a scale greater than $3^{n}$ sites, so that the zero-momentum state is just

Therefore

$$
\begin{equation*}
\frac{1}{\sqrt{2 N+1}} \sum_{j}\langle 0| b_{j}|+\rangle=\frac{1}{N_{b}} \zeta^{(n)} \sum_{p}\left\langle 0_{p}\right| B_{p}\left|+_{p}\right\rangle=\zeta^{(n)} \tag{3.19}
\end{equation*}
$$

Thus

$$
\begin{equation*}
\mathrm{z}_{2}^{1 / 2}=\lim _{\mathrm{n} \rightarrow \infty} \zeta^{(\mathrm{n})}=\prod_{\mathrm{i}=1}^{\infty} \zeta_{\mathrm{i}} \tag{3.20}
\end{equation*}
$$

Using (3.16) and (3.7), we find that in iteration i

$$
\begin{equation*}
\zeta_{\mathrm{i}}=\frac{1}{\sqrt{3}} \sum_{\alpha=-1}^{1}\left(\mathrm{r}_{\alpha}^{(\mathrm{i})}+\mathrm{w}_{\alpha}^{(\mathrm{i})}\right) \tag{3.21}
\end{equation*}
$$

## IV. CONTINUUM THIRRING MODEL

Before discussing results obtained from our renormalization group procedure, we review known features of the continuum solution with which we are interested in making contact. To begin, we recall that operator solutions to the Thirring model have been constructed in two ways. In the first, ${ }^{3}$ the starting point is the formal equations of motion

$$
\begin{align*}
& \mathrm{i} \not \partial \psi=\mathrm{g}_{\mathrm{r}} j^{\prime} \psi  \tag{4.1}\\
& \partial^{\mu} \mathrm{j}_{\mu}(\mathrm{x})=\partial^{\mu}\left(\bar{\psi} \gamma_{\mu} \psi\right)=0 \tag{4.2}
\end{align*}
$$

and

$$
\begin{equation*}
\partial^{\mu} \epsilon_{\mu \nu} j^{\nu}(x)=\partial^{\mu} \mathrm{j}_{5 \mu}(\mathrm{x})=0 \tag{4.3}
\end{equation*}
$$

We refer to these as formal equations since if one begins with the fields $\psi(\mathrm{x})$ as fundamental, the operators $\mathrm{j}_{\mu}(\mathrm{x})$ and $\left(\gamma^{\prime} \psi\right)(\mathrm{x})$ are singular. To give them meaning, one must adopt some prescription for rendering them finite. Johnson does this by introducing a point splitting prescription

$$
\begin{equation*}
\mathrm{j}^{\mu}(\mathrm{x})=\lim _{\epsilon \rightarrow 0} \frac{1}{2}\left\langle\left[\bar{\psi}(\mathrm{x}+\epsilon), \gamma^{\mu} \psi(\mathrm{x}) \bar{j}^{-}\right\rangle-\right. \tag{4,4}
\end{equation*}
$$

where the bracket indicates a suitable averaging process over directions of $\epsilon$ 。 Once both sides of Eq. (4.1) - (4.3) are well defined, it is possible to compute all finite Green's functions.

A second procedure ${ }^{12}$ is to take the currents and their commutators as fundamental, and from these reconstruct the Thirring model and the fermion field. According to this approach, the theory is defined in terms of currents $\mathrm{j}_{\mu}$ and $\mathrm{j}_{5 \mu}$ where $\mathrm{j}_{\mu}(\mathrm{x})$ is assumed to satisfy the commutators

$$
\begin{align*}
& {\left[\mathrm{j}_{0}(\mathrm{x}), \mathrm{j}_{0}(\mathrm{y})\right]_{\mathrm{EQT}}=0}  \tag{4.5}\\
& {\left[\mathrm{j}_{0}(\mathrm{x}), \mathrm{j}_{1}(\mathrm{y})\right]_{\mathrm{EQT}}=\mathrm{ic} \delta^{\prime}(\mathrm{x}-\mathrm{y})} \tag{4.6}
\end{align*}
$$

$$
\begin{equation*}
\left[\mathrm{j}_{1}(\mathrm{x}), \mathrm{j}_{1}(\mathrm{y})\right]_{\mathrm{EQT}}=0 \tag{4,7}
\end{equation*}
$$

and also the conservation laws

$$
\begin{equation*}
\partial^{\mu} j_{\mu}(x)=\partial_{\epsilon \mu \nu}^{\mu} j^{\nu}(x)=0 \tag{4.8}
\end{equation*}
$$

The fermionic degrees of freedom are introduced, after finding general solutions of the problem specified by $(4.5)-(4,8)$, by requiring that there exist a field $\psi(x)$ such that

$$
\begin{align*}
& {\left[\mathrm{j}_{0}(\mathrm{x}), \psi(\mathrm{y})\right]_{\mathrm{EQT}}=-\mathrm{a} \psi(\mathrm{x}) \delta(\mathrm{x}-\mathrm{y})} \\
& {\left[\mathrm{j}_{1}(\mathrm{x}), \psi(\mathrm{y})\right]_{\mathrm{EQT}}=-\overline{\mathrm{a}} \psi(\mathrm{x}) \delta(\mathrm{x}-\mathrm{y})} \tag{4.9}
\end{align*}
$$

A Hamiltonian is then constructed in terms of currents alone in such a way that $\psi(x)$ satisfies the equation

$$
\begin{equation*}
i \not \partial \psi(x)=\mathrm{g}_{\mathrm{r}}: f^{\prime}(\mathrm{x}) \psi(\mathrm{x}): \tag{4.10}
\end{equation*}
$$

where : : indicates an appropriately defined normal ordering prescription for the composite operator.

In either approach, if one studies the full operator solution of the theory, one learns that only two of the four parameters $\left(a, \bar{a}, g_{r}, c\right)$ are independent and that the resulting theory has no mass gap. Moreover, the wave function renormalization $Z_{2}\left(g_{r}\right)$ is found to vanish at a finite value $g_{r}=g_{c r}$ if one adopts Johnson's specific point splitting procedure. The parameter c in (4.6) is singular at $g_{c r}$ as $\frac{1}{1-\left(g_{r} / g_{c r}\right)^{2}}$, and is negative for $g_{r}>g_{c r}$. Thus the Hamiltonian, which when written in terms of light-cone components of the Bose field $j_{\mu}(x)$ is ${ }^{4}$

$$
\begin{equation*}
H=\frac{1}{4 c}\left[\int: j_{+}^{2}(u): d u+\int: j_{-}^{2}(v): d v\right] \tag{4.11}
\end{equation*}
$$

cannot be constructed past this point.

## V. CALCULATION

In this section, we present the calculational details necessary to understand how we numerically carry out and interpret the results of our iterative "renormalization group" procedure for the lattice Thirring model. We find that the picture emerging from our truncation procedure and the resulting equations (3.3)(3.9) is consistent with the continuum model in that there is a finite critical value $\mathrm{g}_{\mathrm{cr}}=1.1087$ such for $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$ the theory has no mass gap; for $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}$ the cutoff lattice theory cannot be multiplicatively renormalized in the usual fashion. The lattice theory still exists for $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}$; in fact, for this region its behavior seems entirely sensible and is precisely as described in Paper II-i.e., for $g>g_{c r}$ we are driven to the strong coupling limit which corresponds to a Heisenberg antiferromagnetic chain with nearest neighbor interactions. As was discussed in Paper II, this theory possesses a massless excitation spectrum as first proved 46 years ago by Bethe. ${ }^{13}$ For $g>g_{c r}$, however, the single particle operator $\frac{1}{\sqrt{\mathrm{~L}}} \int \mathrm{dx} \psi^{+}(\mathrm{x})$ fails to create any finite energy states from the vacuum. In fact, the excitations of unit charge are found to lie an energy $\sim g \Lambda$ above the ground state. This result shows that for a certain region of the parameter $g$ the particles and low-lying excitation spectra found in finite cutoff lattice theories are not simply related to the fundamental field introduced in the starting Lagrangian and Hamiltonian.

In order to describe more fully how we carry out the numerical solution, we recall that the generic form of the Hamiltonian obtained after $n$ iterations will be as given in Eq. (3.9). The problem of storing and recomputing the infinite arrays $X_{n}(j)$ and $Z_{n}(j)$ is handled in our numerical iteration procedure by explicitly computing and storing the values of $X_{n}(j)$ and $Z_{n}(j)$ for $j=1, \ldots, 100$. For $j>100$ we parametrize $X_{n}(j)$ and $A_{n}(j)$ by

$$
\begin{align*}
& X_{n}^{\mathrm{as}}(j)=(-1)^{j}\left[\frac{(\mathrm{~A} 1)_{n}}{j}+\frac{(\mathrm{A} 2)_{n}}{j^{3}}\right]  \tag{5.1}\\
& z_{n}^{\mathrm{as}}(j)=(-1)^{j}\left[\frac{(\mathrm{~B} 1)_{n}}{j}+\frac{(\mathrm{B} 2)_{n}}{j^{3}}+\frac{i(C)_{n}}{j^{2}}\right] \tag{5.2}
\end{align*}
$$

where 'as' stands for asymptotic fit to large ' $\mathbf{j}$ ', and compute the real coefficients $(\mathrm{A} 1)_{n},(\mathrm{~A} 2)_{\mathrm{n}},(\mathrm{B} 1)_{\mathrm{n}},(\mathrm{B} 2)_{\mathrm{n}}$ and $(\mathrm{C})_{\mathrm{n}}$.

Tables V through VII show the results of such a calculation for typical values of $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$ and $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}$. The meaning of the various columns is as follows:
(i) The number of iterations performed.
(ii) The value of $X_{n}$ (1) since it proves convenient for numerical reasons to redefine $H_{n}=X_{n}(1) \times \mathscr{H}_{n}$, where the shortest range part of the gradient term in $\mathscr{H}_{\mathrm{n}}$ is chosen to be normalized to the starting function $\delta^{\prime}(\mathrm{j})$ 。
(iii) $g_{\text {eff }}$ is the value of $g_{n} /\left|X_{n}(1)\right|$ and so, for example, $g_{\text {eff }} \rightarrow 0$ implies that up to an overall scale factor the theory is being driven to a theory with no quartic single site interactions.
(iv) $\mathrm{X}_{\text {norm }}{ }^{\text {(j) }}$ gives the first five values of

$$
\begin{equation*}
X_{n}(\mathrm{j}) \times\left((\mathrm{A} 1)_{\mathrm{n}}+(\mathrm{A} 2)_{\mathrm{n}}\right) / \mathrm{X}_{\mathrm{n}}(1) \times \mathrm{X}_{\mathrm{n}}^{\mathrm{as}}(\mathrm{j}) \tag{5,3}
\end{equation*}
$$

The values of $Z_{n}(j)$ stay small for all initial values of $g$ and iterate to zero relative to $X_{n}(j)$ so that we do not bother to display them here。
(v) (A1) $)_{n} / X_{n}(1),(A 2)_{n} / X_{n}(1)$, etc., are self-explanatory.

We see that if $\mathrm{g}_{\text {eff }}$ and $\mathrm{B} 1 / \mathrm{X}_{\mathrm{n}}(1), \mathrm{B} 2 / \mathrm{X}_{\mathrm{n}}(1)$, and $\mathrm{C} / \mathrm{X}_{\mathrm{n}}(1)$ go to zero as the number of iterations increases and if only $X_{\text {norm }}(\mathrm{j})$ takes a fixed non-zero form, then the Hamiltonian becomes a purely quadratic operator which can be diagonalized simply. Tables $V-V I I$ show that this is what happens for $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$. On the
other hand, for $g>g_{c r}$ we see that $g_{\text {eff }}$ grows; infact, $g_{\text {eff }} \times X_{n}(1)$ approaches a finite value. This means that the quartic terms of the theory dominate the gradient. Moreover, according to Table VII, only the first(i. e., nearest neighbor) part of $X_{n o r m}{ }^{(j)}$ survives an infinite number of iterations. Therefore, the Hamiltonian $\mathscr{H}_{\mathrm{n}} \equiv \mathrm{H}_{\mathrm{n}} / \mathrm{X}_{\mathrm{n}}(1)$ is seen to approach the strong coupling nearest neighbor Thirring model-which was shown in Paper II to be equivalent to the Heisenberg antiferromagnet as studied by Bethe. The results shown are typical of the behavior for all values of $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}{ }^{\circ}$ Since, as is shown in Table VI, the fixed form of $\mathrm{X}_{\text {norm }}{ }^{(\mathrm{j})}$ is the same for all $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$ and is in fact the same as for the free field case $\mathrm{g}=0$, it is evident that, for $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$, the large distance behavior of the Thirring model will be that of a massless free fermion theory. This is of course consistent with what is known about the continuum model.

In order to understand what the change in the behavior of the iterative solution at the point $g=g_{c r}$ signifies, we consider the wave-function renormalization constant $\mathrm{Z}_{2}(\mathrm{~g})$. Since the spectrum for $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$ is always a free massless spectrum, there is no scale in the theory which is set by multiplicatively renormalizing $\psi(\mathrm{x})$ and so there is a great deal of arbitrariness in the definition of $Z_{2}(\mathrm{~g})$. We therefore consider the ratio

$$
\begin{equation*}
\sqrt{\frac{\mathrm{Z}_{2}(\mathrm{~g})}{\mathrm{Z}_{2}(0)}} \equiv \frac{\left\langle+1 \int \mathrm{dx} \psi^{+}(\mathrm{x}) \mid 0\right\rangle_{\mathrm{g}}}{\langle+| \int \mathrm{dx} \psi^{+}(\mathrm{x})|0\rangle_{\mathrm{g}=0}} \tag{5.4}
\end{equation*}
$$

with $Z_{2}(\mathrm{~g})$ defined in (3.14) with $\psi=\sqrt{\Lambda} \chi$.
The result of our renormalization group calculation of this ratio is shown in Fig. 2. Note that it vanishes for $\mathrm{g} \geq \mathrm{g}_{\mathrm{cr}}$, the point dividing the two regions in which the Hamiltonian $H_{n}$ iterates to very different forms. When $\mathrm{g}<\mathrm{g}_{\mathrm{cr}}$, $H_{n}$ converges to the same fixed form that the free $g=0$ Hamiltonian
iterates to, whereas for $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}$ it iterates to the very different form in which the charged fermions move high up to mass $\sim \mathrm{g} \Lambda$ and fail to propagate. This breakdown of multiplicative renormalization and the concomitant loss of the charged degrees of freedom from the finite mass spectrum is interesting in that it seems to occur in several types of lattice theories for appropriate values of coupling constant. Presumably if there is a qualitative difference between nonAbelian gauge theories, to which we look for an explanation of quark confinement, and these non-gauge models, it will be that for the gauge theories whenever $g \neq 0$ we will lose the simple multiplicative renormalization procedure and, with it, propagating free fermion (quark) states. ${ }^{14}$

## CONCLUSION

We have demonstrated that our iterative procedure of constructing an effective Hamiltonian on the lattice can be readily applied to fermion problems and is successful in reproducing known results for the Thirring model.

## APPENDIX: THE SCHWINGER TERM

In the preceding sections we described a technique for calculating the properties of a lattice version of the Thirring model and showed that at least in its most important features it corresponded to the continuum theory. If we wanted to construct a more complete correspondence with the continuum theory, we would have to give expressions for the operators $j_{\mu}(x)$ on a lattice with finite parts that converge to their continuum counterparts. The next step would be to fix the normalization of these operators by computing their matrix elements between an appropriately chosen set of low lying states. As an illustration of such a general program we will discuss here the Schwinger term for this model. The principle purpose of this discussion is (i) to show how to define continuum operators $" j_{\mu}(x)$ " for finite cutoff $\Lambda$ and (ii) to show how to compute matrix elements of this operator and commutators of $\mathrm{j}_{0}(\mathrm{x})$ with $\mathrm{j}_{1}(\mathrm{x})$ between low lying states.

To begin, we observe that our goal is to define a current $j_{\mu}(x)$ satisfying

$$
\begin{equation*}
\partial \mathbf{j}_{\mu} / \partial \mathbf{x}_{\mu}=0 \tag{A.1}
\end{equation*}
$$

and to evaluate the commutator $\left[j_{0}(x, t), j_{1}(y, t)\right]$ which according to (4.6) must be non-vanishing. We can directly construct a conserved current $\rho(\mathrm{x}) \equiv \mathrm{j}_{0}(\mathrm{x})$ and $\mathrm{j}_{1}(\mathrm{x})$ but it turns out technically to be simpler to use Eq。(A。1) and

$$
\begin{equation*}
\dot{\rho}(\mathrm{x})=\mathrm{i}[\mathrm{H}, \rho(\mathrm{x})] \tag{A.2}
\end{equation*}
$$

to rewrite (4.6)

$$
\begin{equation*}
[\rho(\mathrm{x}), \stackrel{\rho}{\rho}(\mathrm{y})]_{\mathrm{EQT}}=\mathrm{i}\left[\rho(\mathrm{x})_{2}[\mathrm{H}, \rho(\mathrm{y})]\right]=-\mathrm{ic} \delta^{\prime \prime}(\mathrm{x}-\mathrm{y}) \tag{A,3}
\end{equation*}
$$

There is no unique description for constructing a local charge density on the lattice. We adopt the straightforward procedure of defining the continuum field ${ }^{15}$

$$
\begin{align*}
\psi(x) & =\sqrt{\Lambda} e^{i P x} \chi(j=0) e^{-i P x} \\
& =\sqrt{\frac{\Lambda}{2 N+1}} \sum_{k=-\pi \Lambda}^{\pi \Lambda} \chi(k) e^{i k x}=\sqrt{\Lambda} \sum_{j=-N}^{N} \chi_{j}\left\{\sum_{K} \frac{e^{i k(x-j / \Lambda)}}{2 N+1}\right\} \\
& =\sqrt{\Lambda} \sum_{j} \chi_{j} \frac{1}{2 N+1}\left(\frac{\sin \pi(\Lambda x-j)}{\sin [\pi(\Lambda x-j) /(2 N+1)]}\right) \\
& \underset{N \rightarrow \infty}{ } \sqrt{\Lambda} \sum_{j} \chi_{j} \frac{\sin \pi(\Lambda x-j)}{\pi(\Lambda x-j)} \tag{A.4}
\end{align*}
$$

and introducing

$$
\begin{align*}
\rho_{\Lambda}(\mathrm{x}) & =\psi^{+}(\mathrm{x}) \psi(\mathrm{x}) \\
& =\Lambda \sum_{\mathrm{j}^{\prime} \mathrm{j}^{\prime}} \chi_{\mathrm{j}}^{+} \chi_{\mathrm{j}^{\prime}!} \quad\left\{\frac{\sin \pi(\Lambda \mathrm{x}-\mathrm{j})}{\pi(\Lambda \mathrm{x}-\mathrm{j})}\right\}\left\{\frac{\sin \pi\left(\Lambda \mathrm{x}-\mathrm{j}^{\prime}\right)}{\pi\left(\Lambda \mathrm{x}-\mathrm{j}^{\prime}\right)}\right) \tag{A.5}
\end{align*}
$$

Next we construct $\frac{\partial \rho(x)}{\partial \mathrm{t}}$ from the equation of motion

$$
\begin{equation*}
\dot{\chi}_{\mathrm{j}}=\mathrm{i}\left[\mathrm{H}, \chi_{\mathrm{j}}\right]=-\mathrm{i} \Lambda\left\{\sum_{\mathrm{j}^{\prime}} \mathrm{i} \delta^{\prime}\left(\mathbf{j}-\mathrm{j}^{\prime}\right) \alpha \chi_{\mathbf{j}^{\mathbf{t}^{\prime}}-\mathrm{g}}\left[\gamma_{0} \chi_{\mathbf{j}}\left(\chi_{\mathrm{j}}^{+} \gamma_{0} \chi_{\mathrm{j}}\right)+\left(\chi_{\mathrm{j}}^{+} \gamma_{0} \chi_{\mathrm{j}}\right) \gamma_{0} \chi_{\mathrm{j}}\right]\right\} \tag{A.6}
\end{equation*}
$$

Using (A.5), we find

$$
\begin{align*}
& \frac{\mathrm{d} \rho}{\mathrm{dt}}=-\mathrm{i} \Lambda^{2} \sum_{\mathrm{j}, \mathrm{j}^{\prime}}\left\{\frac{\sin \pi(\Lambda \mathrm{x}-\mathrm{j})}{\pi(\Lambda \mathrm{x}-\mathrm{j})}\right\}\left\{\frac{\sin \pi\left(\Lambda \mathrm{x}-\mathrm{j}^{\prime}\right)}{\pi\left(\Lambda \mathrm{x}-\mathrm{j}^{\prime}\right)}\right\} \\
& {\left[\chi_{\mathbf{j}}^{+} \quad \alpha \sum_{\mathbf{j}^{\prime \prime}} \mathrm{i} \delta^{\prime}\left(\mathrm{j}^{\prime}-\mathrm{j}^{\prime \prime}\right) \chi_{\mathbf{j}^{\prime \prime}}+\sum_{\mathbf{j}^{\prime \prime}} \chi_{\mathbf{j}^{\prime \prime}}^{+} \quad \alpha \mathrm{i} \delta^{\prime}\left(\mathrm{j}-\mathrm{j}^{\prime \prime}\right) \chi_{\mathbf{j}^{\prime}}\right.} \\
& \left.-2 g\left(\bar{x}_{j^{\prime}} x_{\mathbf{j}}\right)\left(\bar{\chi}_{\mathbf{j}}, \chi_{\mathbf{j}}\right)+2 g\left(\bar{x}_{\mathbf{j}} \chi_{\mathbf{j}}\right)\left(\bar{\chi}_{\mathbf{j}} \chi_{\mathbf{j}^{\prime}}\right)\right] \text { 。 } \tag{A.7}
\end{align*}
$$

We will now evaluate the commutator ( $\mathrm{A}, 2$ ) and verify that the left-hand side (A.3) becomes a c-number which is a function of the coupling $g$ 。 This is easily accomplished once we recognize that at $\mathrm{k}_{\max }$ we can simply pick off the coefficient c in the Schwinger term by averaging the commutator over a cell size $\sim 1 / \Lambda$. In the lattice theory (A. 3) becomes

$$
\begin{equation*}
\left[\rho_{\Lambda}(x), \stackrel{\circ}{\rho}_{\Lambda}(y)\right]_{E Q T}=-i c{ }_{\Lambda} \sum_{k=-\pi \Lambda}^{\pi \Lambda} \frac{-\mathrm{k}^{2} \mathrm{e}^{\mathrm{ik}(\mathrm{x}-\mathrm{y})}}{2 \mathrm{~N}+1} \tag{A.8}
\end{equation*}
$$

An average over the lattice distance is performed by operating on both sides of (A. 8) with

$$
\ell_{x} \ell_{y} \equiv \int_{-d / \Lambda}^{d / \Lambda} d x \int_{-d / \Lambda}^{d / \Lambda} d y
$$

wherc $d \sim 1$. This gives

$$
\begin{equation*}
\left[\ell_{x} \rho_{\Lambda}(x), \ell_{y} \dot{\rho}_{\Lambda}(y)\right]=\frac{4 \pi^{2}}{3} d^{2} \Lambda\left(i c_{\Lambda}\right) \tag{A.10}
\end{equation*}
$$

The calculation of the left-hand side of $\left(\mathrm{A}_{\circ} 10\right)$ is straightforward in the limit $L=\frac{2 N+1}{\Lambda} \rightarrow \infty$ and we find

$$
\frac{8 \mathrm{~d}^{2} \Lambda}{2 \mathrm{~N}+1} \sum_{\mathrm{j}_{1}, \mathrm{j}_{2}} \delta^{\prime}\left(\mathrm{j}_{1}-\mathrm{j}_{2}\right) \chi_{\mathrm{j} 1}^{+} \alpha \chi_{\mathrm{j} 2}=\frac{4 \pi^{2} \mathrm{~d}^{2}}{3} \Lambda\left(\mathrm{i} \mathrm{c}_{\Lambda}\right)
$$

or

$$
\begin{equation*}
c_{\Lambda}=\frac{-6}{\pi^{2}} \frac{\mathrm{~T}}{\Lambda(2 \mathrm{~N}+1)}=\frac{-6 \mathrm{~T}}{\pi^{2} \Lambda^{2} \mathrm{~L}} \tag{A.11}
\end{equation*}
$$

where

$$
\begin{equation*}
T \equiv \Lambda \sum_{j_{1} \mathrm{j}_{2}} \chi_{\mathrm{j} 1}^{+} \quad i \alpha \delta^{\prime}\left(\mathrm{j}_{1}-\mathrm{j}_{2}\right) \chi_{\mathrm{j} 2} \tag{A.12}
\end{equation*}
$$

is the kinetic energy term in the Hamiltonian. This result is independent of the specific form of the quartic interaction terms which are softer at short distances, $i_{.} e_{0}$, the same result ( $\mathrm{A}_{\mathrm{o}} 11$ ) follows from prescriptions for defining the Thirring model on a lattice in terms of a quartic potential term free of Umklapps or of a charge density defined by constructing $\rho(x)$ by the operation ( $A_{0} 4$ ) on the bilinear $\chi_{\mathrm{j}}^{+} \chi_{\mathrm{j}}$. We must now verify that in the limit $\mathrm{L} \rightarrow \infty$, (A.12) becomes a c-number equation. We readily verify this by expressing T in a momentum basis and recognizing its content:

$$
\begin{equation*}
\mathrm{T}=\sum_{\mathrm{k}=-\pi \Lambda}^{\pi \Lambda} \mathrm{k}\left(\mathrm{~b}^{+}(\mathrm{k}) \mathrm{b}(\mathrm{k})-\mathrm{d}^{+}(\mathrm{k}) \mathrm{d}(\mathrm{k})\right) \tag{A.13}
\end{equation*}
$$

The only term in (A.13) proportional to volume $L$ is the zero point energy since all excitations are finite. Note, for the case $\mathrm{g}=0, \mathrm{H}=\mathrm{T}$ and since we know the ground state of the system, we find

$$
\begin{align*}
\langle 0| T|0\rangle & =-2 \sum_{\mathrm{k}=0}^{\pi \Lambda} k+\{\text { finite excitations }\} \\
& =\frac{-\pi \Lambda^{2} L}{2}\left(1+0\left(\frac{1}{\mathrm{~L}}\right)\right) \tag{A.14}
\end{align*}
$$

Hence in the $\mathrm{L} \rightarrow \infty$ limit the free field Schwinger term is given by

$$
\begin{equation*}
c_{\Lambda}=\frac{3}{\pi} \tag{A.15}
\end{equation*}
$$

Finally, one must divide the $c_{\Lambda}$ of (A.11) by $\left(\mathrm{Z}_{2}\right)^{2}$ in order to have the Schwinger term of the currents after field renormalization. ${ }^{3}$ Since $Z_{2} \rightarrow 0$ as $g \rightarrow g_{c r}$, our
c is indeed singular there。 (See Fig. 3.)
Jhhnson has shown that the choice of a value of $\mathrm{g}_{\mathrm{r}}$ and of a point-splitting procedure are sufficient to determine the theory and its Schwinger term. Conversely, choice of values for $g_{r}$ and $c$ determine the theory ${ }^{4}$ and every pair of values corresponds to a point-splitting procedure. ${ }^{5}$ We have given a renormal ization group construction of the operators determining c as a function of the "bare" coupling g. In order to complete the numerical correspondence to the continuum theory, we would have to similarly construct the operators $\not \varnothing \psi$ and $f^{\prime} \psi$, thus finding the "renormalized" ${ }^{16}$ parameter $g_{r}$ 。

13．H．A．Bethe，Z．Phys．71， 205 （1931）。
14．In this context，it is important to note what happens if we use the difference operator for the gradient，which couples only nearest neighbor sites on the lattice，instead of our form $\delta^{\prime}(\mathbf{j})=-(-1)^{\mathbf{j}} / \mathbf{j}$ for all $\mathbf{j} \neq 0$ 。 Recall that the difference operator doubles the number of fermionic degrees of freedom in the $g=0$ free particle theory。 In this case，we find that using the same iteration－truncation procedure described in this paper we are led to a theory of the Heisenberg antiferromagnet for all $g \neq 0$ ．That is，we find $g_{c r}=0$ 。

A。Luther［（Phys。Rev。B14， 2153 （1976）］has derived results for a lat－ tice version of the massive Thirring model which uses the difference oper－ ator for the gradient and assigns particles and anti－particles to alternate lattice sites in order to avoid the doubling of degrees of freedom［in this connection see also J．B．Kogut，＂Three Lectures on Lattice Theory，＂ Cornell University preprint PRINT－76－0865（1976）］．He has found for $m \neq 0$ that there exists a $\mathrm{g}_{\mathrm{cr}} \neq 0$ such that for $\mathrm{g}>\mathrm{g}_{\mathrm{cr}}$ the theory can only be defined by reinterpreting the ground state。
15. These fields satisfy the anticommutation relations

$$
\left\{\psi^{+}(\mathrm{x}), \psi(\mathrm{y})\right\}_{\mathrm{EQT}}=\Lambda \frac{\sin \pi \Lambda(\mathrm{x}-\mathrm{y})}{\pi \Lambda(\mathrm{x}-\mathrm{y})}
$$

with a non-locality resulting from the $\mathrm{k}_{\max }=\pi \Lambda$ cut off.
16. "Renormalized" in the definition (4.1) means after rendering the products finite, and before wave function renormalization.
