Abstract

We have carried out an experimental study of the neutron and proton deep-inelastic electromagnetic structure functions. The structure functions were extracted from electron-proton and electron-deuteron differential cross sections measured in three experiments spanning the angles 6° , 10° , 15° , 18° , 19° , 26° , and 34° . We report primarily on the large angle (15° - 34°) measurements. Neutron cross sections were extracted from the deuteron data using an impulse approximation. Our results are consistent with the hypothesis that the nucleon is composed of point-like constituents. The variation of the cross section with angle suggests that the hypothetical constituents have spin $1/2$. The data for σ_n/σ_p , the ratio of the neutron and proton differential cross sections, are in the range 0.25 to 1.0, and are within the limits imposed by the quark model. Detailed studies of the structure functions were made for a range of the scaling variable ω from $\omega = 1.3$ to $\omega = 10.0$, and for a range of invariant four-momentum transfer, Q^2 , from 1.0 GeV^2 to 20.0 GeV^2 . These studies indicate that the structure functions approximately scale in the variable ω , although significant deviations from scaling in ω are apparent in the region $1.3 < \omega < 3.3$. These deviations from scaling are in the same direction and of similar magnitude for both neutron and proton. The interpretation of the data in terms of various theoretical models is discussed.

Acknowledgements

We wish to express our gratitude and appreciation to all members of the Stanford Linear Accelerator Center. We thank Professor W. K. H. Panofsky and the Technical Division under Dr. R. B. Neal for their support in this experiment. Technical support from the Spectrometer Facilities Group, particularly E. Taylor and Dr. C. K. Sinclair, is much appreciated.

We thank Dr. J. R. Johnson and Dr. R. L. Anderson for their help in the setup of the 1.6 GeV spectrometer. The help of K. Stone and Dr. K. Tsipis in the running of the experiment is much appreciated.

We are indebted to the members of SLAC Group A, particularly Drs. E. D. Bloom, R. L. A. Cottrell, H. DeStaebler, C. L. Jordan, H. Piel and R. E. Taylor for use of the 6° and 10° data and for valuable discussions.

Special thanks goes to W. B. Atwood for making available his resonance fitting procedure and for numerous valuable discussions about deuteron binding effects.

We thank E. Miller and Dr. R. Verdier for programming assistance. Discussions with Dr. G. Miller and help from M. Mestayer and Dr. Steve Stein of Group A are appreciated. We are indebted to Dr. R. L. Jaffe for illuminating discussions about the interpretation of the σ_L/σ_T measurements.

We are grateful to the M.I.T. Physics Department and Laboratory for Nuclear Science for their support of the M.I.T. collaborators.
