# PHOTON STRUCTURE FUNCTIONS AND AZIMUTHAL ASYMMETRIES IN TWO-PHOTON PROCESSES* <br> Jiro Kodaira ${ }^{\dagger}$ <br> Stanford Linear Accelerator Center Stanford University, Stanford, California 95305 U.S.A. and <br> Atsushi Higuchi and Satoshi Matsuda Department of Physics Kyoto University, Kyoto 606, Japan 

ABSTRACT

Based on the recently developed framework of Curci, Furmanski and Petronzio, we derive the photon structure functions in quantum chromodynamics (QCD). Then we perform QCD calculations for the azimuthal asymmetries of jets in two-photon processes. We find that in contrast to the case of lepton-hadron scatterings the deep inelastic $e^{+} e^{-}$reaction via two-photon exchange is expected to show cleaner signatures for the azimuthal asymmetries as a result of enhanced QCD effects. We suggest that these will serve as useful tests of QCD.

Submitted to Physical Review D

[^0]
## 1. INTRODUCTION

Today quantum chromodynamics (QCD) is regarded as the most promising candidate for the field theory of strong interactions. The quantitative test of QCD has now become one of the most important tasks imposed upon particle physicists. Now that the proof of the factorization of mass singularities is completed, ${ }^{1}$ perturbative QCD calculations can be attempted in a wide range of deep inelastic processes.

Among the most interesting processes is the two-photon collision which appears in $e^{+} e^{-}$colliding experiments. ${ }^{2}$ Many authors have studied this process by now. ${ }^{3-10}$ In this paper we point out that clean tests of QCD effects are expected to be operative in the two-photon process. This is because the leading behavior, with respect to $Q^{2}$, of the photon structure functions is exactly calculable as was first shown correctly by Witten. ${ }^{4}$ Also the Weizsäcker-Williams approximation allows us to study the structure functions of the electron as well as those of the photon on equal footing.

First we derive the photon structure functions in the framework developed by Curci, Furmanski and Petronzioll (refered to as CFP). Particularly, our presentation will be helpful to clarify the parton view of the $Q^{2}$ evolution of the photon structure functions. It also exhibits naturally how the factorized collinear mass singularities of the photon structure functions are to be absorbed into the hadronic components of the target photon. With this study on the photon structure functions, we then investigate the azimuthal asymmetries of jets in the deep inelastic $e^{+} e^{-}$scattering, aiming at clean and hopefully critical, tests of QCD.

The azimuthal asymmetries in lepton-hadron deep inelastic scatterings were first studied in the context of $Q C D$ effects by Georgi and Politzer. ${ }^{12}$ They claimed that the azimuthal asymmetries in the above reactions would provide clean tests of QCD. But it was subsequently shown by Cahn ${ }^{13}$ that similar nonzero effects in the azimuthal asymmetries would result from the naive parton model (NPM) ${ }^{14}$ by incorporating primordial transverse momentum $k_{T}$. Moreover, it was shown by Binétruy and Girardil 5 that it is very difficult to discriminate the QCD effects from the primordial $k_{T}$ effects since both contribute competitively to the azimuthal asymmetries in the case of the lepton-hadron scatterings. We find that this difficulty arises primarily from the inherent nonperturbative QCD ambiguities remaining in the structure functions of the hadron target.

We show in the present paper that in the deep inelastic $e^{+} e^{-}$scattering via two-photon exchange where the structure functions of the photon and, as a result, those of the electron are exactly calculable up to the leading order of $\ln Q^{2}$, one is free from the above-mentioned ambiguities, thus can predict the enhanced QCD effects for the azimuthal asymmetries against the background effects due to primordial $\mathrm{k}_{\mathrm{T}}$. We claim that in contrast to those in the lepton-hadron scatterings the azimuthal asymmetries in the two-photon process could be useful to make clean tests of QCD. In the later sections we present the detailed features of the azimuthal asymmetries in perturbative QCD calculations.

In Sec. 2 we study the photon structure functions. In Sec. 3 parton cross sections for our problem are presented. The main results for the azimuthal asymmetries are reported in Sec. 4. In Sec. 5 we give our conclusions and some remarks. Appendices $A$ and $B$ are included to give formulae for anomalous dimensions and calculations for parton cross sections.

## 2. PHOTON AND ELECTRON STRUCTURE FUNCTIONS

In this section we derive the photon structure functions to the leading order of $\ln Q^{2}$ in the CFP framework. Although the obtained results are well known, the recently developed technique of CFP allows us to exhibit very nicely how the factorized collinear mass singularities associated with the point-like photon dissociation into a quarkantiquark pair are to be absorbed into the hadronic components of the target photon. We identify the hadronic components as the vector meson dominance (VMD) contribution to simplify our arguments.

Also one big advantage of the present method is that the justification of the usual procedure of jet calculations, i.e., the convolution of the universal $Q^{2}$ dependent structure functions with parton cross sections, can be done very easily in the framework adopted here.

With the photon structure functions given, it is straightforward to obtain the structure functions of the electron in terms of the wellknown equivalent photon method due to Weizsäcker-Williams.

Following Ref. 11, we use the light-like gauge and the minimal subtraction scheme for dealing with mass singularities.

First we discuss the general method for obtaining the $Q^{2}$ dependence of the "structure function of partons". Assume there are several kinds of partons: $\dot{\alpha}, \beta, \delta, \ldots=q, \bar{q}, G, \gamma, \ldots$ where $q, \bar{q}$ stand for quark or antiquark, $G$ for gluon, $\gamma$ for photon, and indices for flavor and color degrees are suppressed. We denote the structure function of parton $\alpha$ by

$$
\begin{equation*}
F_{\alpha}^{B}\left(\frac{Q^{2}}{\mu^{2}}, x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right) \tag{2.1}
\end{equation*}
$$

where x is the Bjorken variable of deep inelastic scattering on parton $\alpha$. The symbol $B$ means "bare", thus $F_{\alpha}^{B}$ contain the mass singularities generated in $4+\varepsilon$ dimensions. ${ }^{11}$

Following the procedure shown by CFP, i.e., the two particle irreducible ladder expansion to factorize mass singularities, we define the "renormalized" structure functions $F_{\alpha}^{R}\left(\left(Q^{2} / \mu^{2}\right), x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}\right)$ and the "renormalization constants" $\Gamma_{\alpha \beta}\left(x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m},(1 / \varepsilon)\right)$ which are related (or defined) to satisfy

$$
\begin{align*}
\mathrm{F}_{\alpha}^{\mathrm{B}}\left(\frac{Q^{2}}{\mu^{2}}, \mathrm{x}, \alpha_{\mathrm{s}}\left(\mu^{2}\right), \alpha_{\mathrm{em}}, \frac{1}{\varepsilon}\right) & =\int_{0}^{1} \mathrm{dy} \mathrm{~F}_{\beta}^{\mathrm{R}}\left(\frac{Q^{2}}{\mu^{2}}, \mathrm{y}, \alpha_{\mathrm{s}}\left(\mu^{2}\right), \alpha_{\mathrm{em}}\right)  \tag{2.2}\\
& \times \int_{0}^{1} \mathrm{~d} z \Gamma_{\beta \alpha}\left(\mathrm{z}, \alpha_{\mathrm{s}}\left(\mu^{2}\right), \alpha_{\mathrm{em}}, \frac{1}{\varepsilon}\right) \delta(\mathrm{x}-\mathrm{yz}) .
\end{align*}
$$

Taking the x moments, we obtain

$$
\begin{align*}
F_{\alpha}^{B}\left(\frac{Q^{2}}{\mu^{2}}, N, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right) & =F_{\beta}^{R}\left(\frac{Q^{2}}{\mu^{2}}, N, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}\right) \\
& \times \Gamma_{\beta \alpha}\left(N, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right) \tag{2.3}
\end{align*}
$$

Since $F_{\alpha}^{B}$ as introduced in Ref. 11 is a "bare" quantity and does not depend on $\mu$, we should have

$$
\begin{equation*}
\mu \frac{d}{d \mu} F_{\alpha}^{B}=0 \tag{2.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\mu \frac{d}{d \mu} F_{\beta}^{R}\right) \Gamma_{\beta \alpha}+F_{\beta}^{R}\left(\mu \frac{d}{d \mu} \Gamma_{\beta \alpha}\right)=0 \tag{2.5}
\end{equation*}
$$

Therefore,

$$
\begin{equation*}
\mu \frac{d}{d \mu} F_{\alpha}^{R}-\gamma_{\beta \alpha} F_{\beta}^{R}=0 \tag{2.6}
\end{equation*}
$$

where

$$
\begin{equation*}
\gamma_{\beta \alpha} \equiv-\left(\mu \frac{\mathrm{d}}{\mathrm{~d} \mu} \Gamma_{\beta \delta}\right) \Gamma_{\delta \alpha}^{-1} \tag{2.7}
\end{equation*}
$$

The total derivative over $\mu$ is given by

$$
\begin{equation*}
\mu \frac{d}{d \mu}=\mu \frac{\partial}{\partial \mu}+\beta\left(g_{s}, \varepsilon\right) \frac{\partial}{\partial g_{s}}+\beta_{e m}(e, \varepsilon) \frac{\partial}{\partial \mathrm{e}} \tag{2.8}
\end{equation*}
$$

where

$$
\begin{equation*}
\beta\left(g_{s}, \varepsilon\right)=\beta\left(g_{s}\right)+\frac{1}{2} \varepsilon g_{s}, \tag{2.9}
\end{equation*}
$$

and

$$
\begin{equation*}
\beta_{e m}(e, \varepsilon)=\beta_{e m}(e)+\frac{1}{2} \varepsilon e \tag{2.10}
\end{equation*}
$$

are the Peterman-Stueckelberg-Ge11-Mann-Low ${ }^{16} \beta$-functions in $4+\varepsilon$ dimensions.

In the following we only consider the case of lowest order in $\alpha_{\text {em }}$, so, taking the limit $\varepsilon \rightarrow 0$, we obtain from (2.6) and (2.8)

$$
\begin{equation*}
\left(\mu \frac{\partial}{\partial \mu}+\beta\left(g_{s}\right) \frac{\partial}{\partial g_{s}}\right) F_{\alpha}^{R}=F_{\beta}^{R} \gamma_{B \alpha} \tag{2.11}
\end{equation*}
$$

where from (2.7) we have

$$
\begin{equation*}
\gamma_{\beta \alpha}\left(N, \alpha_{s}(\mu), \alpha_{\mathrm{em}}\right)=-\left(\beta\left(\mathrm{g}_{\mathrm{s}}, \varepsilon\right) \frac{\partial}{\partial g_{\mathrm{s}}}+\beta_{\mathrm{em}}(e, \varepsilon) \frac{\partial}{\partial \mathrm{e}}\right) \Gamma_{\beta \delta}\left(\Gamma^{-1}\right)_{\delta \alpha} \tag{2.12}
\end{equation*}
$$

since $\Gamma_{\alpha \beta}$ does not have explicit $\mu$ dependence.
Solving (2.11) we obtain

$$
\begin{align*}
\mathrm{F}_{\alpha}^{\mathrm{R}}\left(\frac{Q^{2}}{\mu^{2}}, \mathrm{~N}, \alpha_{\mathrm{s}}\left(\mu^{2}\right), \alpha_{\mathrm{em}}\right) & =\mathrm{F}_{\beta}^{\mathrm{R}}\left(1, \mathrm{~N}, \alpha_{\mathrm{s}}\left(Q^{2}\right), \alpha_{\mathrm{em}}\right) \\
& \times\left(\mathrm{T}^{*} \exp \left[\int_{\mathrm{g}_{\mathrm{s}}\left(Q^{2}\right)}^{g_{\mathrm{s}}^{\left(\mu^{2}\right)} \frac{\leftrightarrow}{\beta(\mathrm{g})}} \mathrm{dg}\right]\right)_{\beta \alpha} \tag{2.13}
\end{align*}
$$

where the anti-time ordering is defined by

$$
\begin{align*}
T^{*} \exp \left[\int_{a}^{b} \stackrel{\leftrightarrow}{f}(t) d t\right] \equiv & \sum_{n=0}^{\infty} \int_{a}^{b} d t_{n} \int_{a}^{t_{n}} d t_{n-1} \cdots \int_{a}^{t_{2}} d t_{1} \\
& \times \overleftrightarrow{f}\left(t_{1}\right) \stackrel{\leftrightarrow}{f}\left(t_{2}\right) \ldots \overleftrightarrow{f}\left(t_{n}\right) \tag{2.14}
\end{align*}
$$

and $\alpha_{s}\left(Q^{2}\right)=\alpha_{s}\left(\left(Q^{2} / \mu^{2}\right), \alpha_{s}\left(\mu^{2}\right)\right)$ satisfies

$$
\begin{equation*}
\left(\mu \frac{\partial}{\partial \mu}+\beta\left(g_{s}\right) \frac{\partial}{\partial g_{s}}\right) \alpha_{s}\left(Q^{2}\right)=0 \tag{2.15}
\end{equation*}
$$

In the lowest order of $\alpha_{\text {em }}$ the anomalous dimension matrix is effectively given by
because the $\gamma^{\prime}$ s of the bottom row are at most $0\left(\alpha_{e m}\right)$ and couple to fundLions of $O\left(\alpha_{e m}\right)$, therefore start to contribute only to the part of $O\left(\alpha_{e m}^{2}\right)$. Substituting (2.16), we get

$$
\begin{align*}
& T^{*} \exp \left[\int_{g_{S}\left(Q^{2}\right)}^{g_{S}\left(\mu^{2}\right)} \frac{\leftrightarrow}{\beta(g)} d g\right]_{\beta \alpha} \tag{2.17}
\end{align*}
$$

We define the renormalized $Q^{2}$-dependent structure functions $f_{\beta \alpha}^{R}\left(\left(Q^{2} / \mu^{2}\right), x\right)$ by

$$
\begin{equation*}
\int_{0}^{1} d x x^{N-1} f_{\beta \alpha}^{R}\left(\frac{Q^{2}}{\mu^{2}}, x\right) \equiv T^{*} \exp \left[\int_{g_{s}\left(Q^{2}\right)}^{g_{S}\left(\mu^{2}\right)} \frac{\gamma(g)}{\beta(g)} d g\right]_{\beta \alpha} \tag{2.18}
\end{equation*}
$$

Then we have

$$
\begin{align*}
F_{\alpha}^{R}\left(\frac{Q^{2}}{\mu^{2}}, x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}\right) & =\int_{0}^{1} d y F_{\beta}^{R}\left(1, y, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}\right) \\
& \times \int_{0}^{1} d z f_{\beta \alpha}^{R}\left(\frac{Q^{2}}{\mu^{2}}, z\right) \delta(x-y z) . \tag{2.19}
\end{align*}
$$

Finally, defining $f_{\beta \alpha}^{B}\left(\left(Q^{2} / \mu^{2}\right), x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m},(1 / \varepsilon)\right)$ by

$$
\begin{array}{r}
f_{\beta \alpha}^{B}\left(\frac{Q^{2}}{\mu^{2}}, x, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right)=\int_{0}^{1} d y f_{\beta \delta}^{R}\left(\frac{Q^{2}}{\mu^{2}}, y\right) \\
\times \int_{0}^{1} \mathrm{dz} \Gamma_{\delta \alpha}\left(z, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right) \delta(x-y z), \tag{2.20}
\end{array}
$$

we obtain

$$
\begin{align*}
& -F_{\alpha}^{B}\left(\frac{Q^{2}}{\mu^{2}}, x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right)=\int_{0}^{1} d y F_{\beta}^{R}\left(1, y, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}\right) \\
& \quad \times \int_{0}^{1} d z f_{\beta \alpha}^{B}\left(\frac{Q^{2}}{\mu^{2}}, z, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right) \delta(x-y z) . \tag{2.21}
\end{align*}
$$

It is to be noted that in (2.19) and (2.21) the structure function is factorized into the hard parton cross section $F_{\beta}^{R}\left(1, y, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}\right)$ and the universal $Q^{2}$-dependent parton structure function $f_{\beta \alpha}^{B}$. By the usual
procedure the outgoing partons encountered in calculating $F_{\beta}^{R}\left(1, y, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}\right)$ can be identified as exclusive jets. Then if we are interested in the generalized structure functions $F_{\alpha}^{B}\left(Q^{2} / \mu^{2}\right), \mathrm{x}, \mathrm{w}^{\prime} \mathrm{s}$, $\left.\alpha_{s}\left(Q^{2}\right), \alpha_{e m},(l / \varepsilon)\right)$ including the jet variables $w^{\prime} s$ which describe jets produced in the final state of deep inelastic scattering on parton $\alpha$, we just substitute $F_{\beta}^{R}\left(1, y, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}\right)$ by the exclusive parton cross section $F_{\beta}^{R}\left(1, y, w^{\prime} s, \alpha_{s}\left(Q^{2}\right), \alpha_{e m}\right)$ in (2.21). In this way we obtain

$$
\begin{array}{r}
\mathrm{F}_{\alpha}^{\mathrm{B}}\left(\frac{Q^{2}}{2}, \mathrm{x}, \mathrm{w}^{\prime} \mathrm{s}, \alpha_{\mathrm{s}}\left(Q^{2}\right), \alpha_{\mathrm{em}}, \frac{1}{\varepsilon}\right)=\int_{0}^{1} \mathrm{dy} \mathrm{~F}_{\beta}^{\mathrm{R}}\left(1, \mathrm{y}, \mathrm{w}^{\prime} \mathrm{s}, \alpha_{\mathrm{s}}\left(Q^{2}\right), \alpha_{\mathrm{em}}\right) \\
 \tag{2.22}\\
\times \int_{0}^{1} \mathrm{dz} f_{\beta \alpha}^{B}\left(\frac{Q^{2}}{\mu^{2}}, z, \alpha_{s}\left(\mu^{2}\right), \alpha_{\mathrm{em}}, \frac{1}{\varepsilon}\right) \delta(\mathrm{x}-\mathrm{yz}) .
\end{array}
$$

When the target is a usual hadron $h$, we define its $Q^{2}$-dependent structure function by the convolution

$$
\begin{equation*}
f_{a h}\left(x, Q^{2}\right)=\int_{0}^{1} d y f_{a b}^{B}\left(\frac{Q^{2}}{\mu^{2}}, y, \alpha_{s}\left(\mu^{2}\right), 0, \frac{1}{\varepsilon}\right) f_{b h}^{B}\left(z, \frac{1}{\varepsilon}\right) \delta(x-y z), \tag{2.23}
\end{equation*}
$$

where the italics $a, b$ stand for $q, \bar{q}$ and $G$, and $f_{a h}^{B}(x,(1 / \varepsilon))$ is the bare parton density in the hadron. $f_{a h}\left(x, Q^{2}\right)$ can also be expressed as

$$
\begin{equation*}
f_{a h}\left(x, Q^{2}\right)=\int_{0}^{1} d y f_{a b}^{R}\left(\frac{Q^{2}}{\mu}, y\right) \int_{0}^{1} d z f_{b h}^{R}(z) \delta(x-y z) \tag{2.24}
\end{equation*}
$$

where

$$
\begin{equation*}
f_{a h}^{R}(x)=\int_{0}^{1} d y \Gamma_{a b}\left(y, \alpha_{s}\left(\mu^{2}\right), 0, \frac{1}{\varepsilon}\right) \int_{0}^{1} d z f_{b h}^{B}\left(z, \frac{1}{\varepsilon}\right) \delta(x-y z) . \tag{2.25}
\end{equation*}
$$

$f_{a h}\left(x, Q^{2}\right)$, or equivalently $f_{a h}^{R}(x)$, must be finite according to the KLN
theorem. ${ }^{17,18}$ From (2.22) we thus get the usual procedure of convoluting the $Q^{2}$-dependent structure functions with parton cross sections

$$
\begin{align*}
F_{h}\left(\frac{Q^{2}}{2}, x, w^{\prime} s, \alpha_{s}\left(\mu^{2}\right)\right) & =\int_{0}^{1} d y F_{a}^{R}\left(1, y, w^{\prime} s, \alpha_{s}\left(Q^{2}\right), 0\right) \\
& \times \int_{0}^{1} d z f_{a h}\left(z, Q^{2}\right) \delta(x-y z) \tag{2.26}
\end{align*}
$$

In the case of a photon target, the situation is somewhat different. The target photon ' $\gamma$ ' has the bare parton densities

$$
\begin{equation*}
f_{\alpha^{\prime} \gamma^{\prime}}^{B}\left(x, \frac{1}{\varepsilon}\right)=\delta(1-x) \delta_{\alpha \gamma}+f_{\alpha^{\prime} \gamma^{\prime}}^{B(V M D)}\left(x, \frac{1}{\varepsilon}\right)+o\left(\alpha_{\mathrm{em}}^{2}\right) \tag{2.27}
\end{equation*}
$$

where the first term represents the contribution of the target photon acting as a bare parton $\gamma$, while the second stands for the hadronic components inside the target photon which are typified by the VMD contribution. Also we note that in the CFP framework we have

$$
\begin{equation*}
\Gamma_{\gamma \gamma}\left(x, \frac{1}{\varepsilon}\right)=\delta(1-x)+o\left(\alpha_{\mathrm{em}}^{2}\right) \tag{2.28}
\end{equation*}
$$

Then, convoluting (2.27) with (2.20) and using (2.28), we obtain the finite $Q^{2}$-dependent structure functions of the target photon ' $\gamma$ ':

$$
\begin{align*}
& f_{a^{\prime} \gamma^{\prime}}\left(x, Q^{2}\right)=f_{a \gamma}^{R}\left(\frac{Q^{2}}{\mu^{2}}, x\right) \\
& \quad+\int_{0}^{1} d y f_{a b}^{R}\left(\frac{Q^{2}}{\mu^{2}}, y\right) f_{b^{\prime} \gamma^{\prime}}^{R(V M D)}(z) \delta(x-y z)+o\left(\alpha_{e m}^{2}\right) \tag{2.29}
\end{align*}
$$

where the italics $a$ and $b$ denote $q, \bar{q}$ and $G$, and the renormalized parton densities $f_{a^{\prime} \gamma^{\prime}}^{R(V M D)}$ corresponding to the $V M D$ component of the target photon
is given by

$$
\begin{align*}
& f_{a^{\prime} \gamma^{\prime}}^{R(V M D)}(x)=\Gamma_{a \gamma}\left(x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m}, \frac{1}{\varepsilon}\right) \\
& \quad+\int_{0}^{1} d y \Gamma_{a b}\left(y, \alpha_{s}\left(\mu^{2}\right), 0, \frac{1}{\varepsilon}\right) \int_{0}^{1} d z f_{b^{\prime} \gamma^{\prime}}^{B(V M D)}\left(z, \frac{1}{\varepsilon}\right) \delta(x-y z) \tag{2.30}
\end{align*}
$$

This result exhibits explicitly the manner in which the collinear mass singularities associated with the "renormalization constants" $\Gamma_{a \gamma}\left(x, \alpha_{s}\left(\mu^{2}\right), \alpha_{e m} ;(1 / \varepsilon)\right)$ are absorbed into the hadronic components of the target photon.

Following Ref. 11, we now calculate $\Gamma^{\prime} s$. It is straightforward to obtain the $\Gamma^{\prime}$ 's to the order needed to get the leading behavior of $F_{\gamma}^{B}$. The results are

$$
\begin{align*}
& \Gamma_{\mathrm{qq}}(\mathrm{x})=\delta(1-\mathrm{x})+\frac{2}{\varepsilon} \frac{\alpha_{\mathrm{S}}(\mu)}{2 \pi} \mathrm{P}_{\mathrm{qq}}(\mathrm{x}) ; \Gamma_{\mathrm{qG}}(\mathrm{x})=\frac{2}{\varepsilon} \frac{\alpha_{\mathrm{S}}(\mu)}{2 \pi} \mathrm{P}_{\mathrm{qG}}(\mathrm{x}) \\
& \Gamma_{\mathrm{Gq}}(\mathrm{x})=\frac{2}{\varepsilon} \frac{\alpha_{\mathrm{S}}(\mu)}{2 \pi} \mathrm{P}_{\mathrm{Gq}}(\mathrm{x}) \quad ; \quad \Gamma_{\mathrm{GG}}(\mathrm{x})=\delta(1-\mathrm{x})+\frac{2}{\varepsilon} \frac{\alpha_{\mathrm{S}}(\mu)}{2 \pi} \mathrm{P}_{\mathrm{GG}}(\mathrm{x}) ; \tag{2.31}
\end{align*}
$$

where the $P^{\prime} s$ are the well-known Altarelli-Parisi ${ }^{19}$ probability functions and

$$
\begin{equation*}
\Gamma_{\mathrm{q} \mathrm{\gamma}}(x)=\frac{2}{\varepsilon} \frac{\alpha_{e m}}{2 \pi}\left[x^{2}+(1-x)^{2}\right] \tag{2.32}
\end{equation*}
$$

The other $\Gamma^{\prime}$ s may be set equal to zero. Taking the $x$ moments of (2.31) and (2.32), we get $\gamma^{\prime}$ s from (2.7). Since the obtained $\gamma^{\prime}$ s turn out to be the same as the anomalous dimensions appearing in the operator product expansion (OPE), we substitute them into (2.17) and obtain the following known results from (2.18):

$$
\begin{align*}
& \int_{0}^{1} d x x^{N-1} f_{q^{i} q j}^{R}\left(x, \frac{Q^{2}}{\mu^{2}}\right)=\left(\delta_{i j}-\frac{1}{2 f}\right)\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{N S}} \\
& +\frac{1}{2 f}\left[\frac{d_{N}^{+}-d_{N}^{G G}}{d_{N}^{+}-d_{N}^{-}}\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{+}}+\frac{d_{N}^{G G}-d_{N}^{-}}{d_{N}^{+}-d_{N}^{-}}\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{-}}\right] \\
& \int_{0}^{1} d x x^{N-1} f_{q^{i} G}^{R}\left(x, \frac{Q^{2}}{\mu^{2}}\right)=\frac{1}{2 f} \frac{d_{N}^{q G}}{d_{N}^{+}-d_{N}^{-}}\left[\left(\frac{\alpha_{S}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{-}}-\left(\frac{\alpha_{S}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{+}}\right], \\
& \int_{0}^{1} d x x^{N-1} f_{G q i}^{R}\left(x, \frac{Q^{2}}{\mu^{2}}\right)=\frac{d_{N}^{G q}}{d_{N}^{+}-d_{N}^{-}}\left[\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{-}}-\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{+}}\right], \\
& \int_{0}^{1} d x x^{N-1} f_{G G}^{R}\left(x, \frac{Q^{2}}{\mu^{2}}\right)=\frac{d_{N}^{+}-d_{N}^{G G}}{d_{N}^{+}-d_{N}^{-}}\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{-}}+\frac{d_{N}^{G G}-d_{N}^{-}}{d_{N}^{+}-d_{N}^{-}}\left(\frac{\alpha_{s}\left(Q^{2}\right)}{\alpha_{s}\left(\mu^{2}\right)}\right)^{d_{N}^{+}} \tag{2.33}
\end{align*}
$$

and

$$
\begin{align*}
& \int_{0}^{1} d x x^{N-1} f_{q^{R}}^{R}\left(x, \frac{Q^{2}}{\mu^{2}}\right)=\frac{3 a}{2 \pi} \ln \frac{Q^{2}}{\Lambda^{2}} d_{N}^{q \gamma} \\
& \times\left\{\left(e_{i}^{2}-\left\langle e^{2}\right\rangle\right) \frac{1}{1+d_{N}^{N S}}+\left\langle e^{2}\right\rangle \frac{1+d_{N}^{G G}}{\mathrm{~K}_{\mathrm{N}}}\right\} \quad, \\
& \int_{0}^{1} d x x^{N-1} f_{G \gamma}^{R}\left(x, \frac{Q^{2}}{\mu^{2}}\right)=2 f \frac{3 \alpha e m}{2 \pi} \ln \frac{Q^{2}}{\Lambda^{2}} d_{N}^{q \gamma}\left\langle e^{2}\right\rangle \frac{d^{G q}}{K_{N}} \tag{2.34}
\end{align*}
$$

where $f$ is the number of flavors, $K_{N}$ is

$$
\begin{equation*}
\mathrm{K}_{\mathrm{N}}=1+\mathrm{d}_{\mathrm{N}}^{\mathrm{NS}}+\mathrm{d}_{\mathrm{N}}^{\mathrm{GG}}+\mathrm{d}_{\mathrm{N}}^{\mathrm{NS}} \mathrm{~d}_{\mathrm{N}}^{\mathrm{GG}}-\mathrm{d}_{\mathrm{N}}^{\mathrm{qG}} \mathrm{~d}_{\mathrm{N}}^{\mathrm{Gq}} \tag{2.35}
\end{equation*}
$$

and d's are cited in Appendix A.

Now from (2.29) we have

$$
\begin{equation*}
f_{a^{\prime} \gamma^{\prime}}\left(x, Q^{2}\right)=f_{a \gamma}^{R}\left(\frac{Q^{2}}{\mu^{2}}, x\right)+f_{a^{\prime} \gamma^{\prime}}^{V M D}\left(x, Q^{2}\right) \tag{2.36}
\end{equation*}
$$

with

$$
\begin{equation*}
f_{a^{\prime} \gamma^{\prime}}^{\mathrm{VMD}}\left(x, Q^{2}\right)=\int_{0}^{1} \mathrm{dy} f_{a b}^{R}\left(\frac{Q^{2}}{\mu^{2}}, y\right) f_{b^{\prime} \gamma^{\prime}}^{R(V M D)}(z) \delta(x-y z), \tag{2.37}
\end{equation*}
$$

and $a, b=q, \bar{q}, G$. Since in (2.33) and (2.34) all d's are positive, we find that for very large $Q^{2}$ the second term due to VMD is suppressed. So the photon structure functions $F_{a^{\prime} \gamma^{\prime}}\left(x, Q^{2}\right)$ is predominated by the photonparton contribution $f_{a \gamma}^{R}\left(\left(Q^{2} / \mu^{2}\right), x\right)$ which is exactly given by (2.34). We observe that this leading contribution behaves like $\ln Q^{2}$. Performing the inverse Mellin transformation from (2.34), we obtain the x dependence of $f_{a \gamma}^{R}\left(\left(Q^{2} / \mu^{2}\right), x\right)$. We present our results for 3 flavors (see Fig. 1). For the case of 4 flavors, refer to Ref. 9.

Although $\mathrm{f}_{a^{\prime} \gamma^{\prime}}^{\mathrm{VMD}}$ is expected smaller than the next-to-leading order correction of $f_{a \gamma}^{R}$ in the $Q^{2} \rightarrow \infty$ limit, in the following analysis at large but finite $Q^{2}$ we include $f_{a^{\prime} \gamma^{\prime}}^{\mathrm{VMD}}$, particularly to estimate the possible nonperturbative contribution of primordial $\mathrm{k}_{\mathrm{T}}$ to the angular asymmetries. On the other hand we expect that the next-to-leading order correction to the distribution functions will not affect substantially the angular asymmetries because the latter mainly reflect the characteristics of parton cross sections but not of the distribution function.
$f_{a^{\prime} \gamma^{\prime}}^{\mathrm{VMD}}$ is basically unknown in the present scheme since $f_{b^{\prime} \gamma^{\prime}}^{R(V M D)}(z)$ is not given in (2.37). Therefore we use for these parts the vector dominance model (VDM) and assume simple structure functions for vector mesons as many authors do. $4,6,9$ Moreover we neglect the gluon distribution from VDM and the $Q^{2}$-dependence in the assumed structure functions.

This simplification is valid for our present study since our point here is to show explicitly that their corrections do not spoil the characteristic signatures of the leading QCD effects for the azimuthal asymmetries. For $f_{q^{i^{\prime}} \gamma^{\prime}}^{\mathrm{VMD}}$ (x) we get by VDM

$$
\begin{equation*}
f_{q^{\prime} \gamma^{\prime}}^{V M D}(x)=\sum_{V} \frac{4 \pi \alpha_{e m}}{f_{V}^{2}} f_{q^{i} V}(x) \simeq \frac{4 \pi \alpha_{e m}}{f_{\rho}^{2}} f_{q^{i} \rho}(x) \tag{2.38}
\end{equation*}
$$

From the experimental value of $\Gamma_{\rho} \mathrm{O} \rightarrow \mathrm{e}^{+} e^{-}$we obtain roughly

$$
\frac{\mathrm{f}_{\rho}^{2}}{4 \pi} \approx 2
$$

Assuming $f_{q^{i} \rho^{\circ}} \propto(1-x) / x$ and $50 \%$ of the gluon component we finally get

$$
\begin{equation*}
\mathrm{f}_{\mathrm{q}^{i^{\prime} \gamma^{\prime}}}^{\mathrm{VMD}}(\mathrm{x}) \simeq \frac{\alpha \mathrm{em}}{2}\langle\mathrm{x}\rangle_{\mathrm{q}^{i}} \frac{1-\mathrm{x}}{\mathrm{x}} \tag{2.39}
\end{equation*}
$$

where the average momentum $\langle x\rangle{ }_{q i}$ carried by the quarks inside $\rho^{0}$ is taken to be

$$
\langle x\rangle_{q^{i}}= \begin{cases}0.25 & \text { for } u, \bar{u}, d, \bar{d}  \tag{2.40}\\ 0 & \text { for } s, \bar{s}, c, \bar{c}\end{cases}
$$

It is rather a rough estimation but sufficient for our purpose.
The electron structure function is obtained using the equivalent photon approximation. Since we restrict ourselves to the single tag events, we should use the following form of the equivalent photon spectrum (in the leading approximation)

$$
\begin{equation*}
\frac{\mathrm{dN}}{\mathrm{dx}}=\frac{\alpha \mathrm{em}}{2 \pi} \ln \frac{s \theta_{\max }^{2}}{4 m_{e}^{2}} \frac{1+(1-x)^{2}}{x} \tag{2.41}
\end{equation*}
$$

where x is not too close to 0 or 1 , and the electron is constrained to lie inside a cone of half-angle $\theta_{\text {max }}$. By the convolution

$$
\begin{equation*}
f_{a e}\left(x, Q^{2}\right)=\int_{x}^{1} \frac{d z}{z} \frac{d N}{d z} f_{a^{\prime} \gamma^{\prime}}\left(\frac{x}{z}, Q^{2}\right) \tag{2.42}
\end{equation*}
$$

we get the structure functions of the electron.
The results of the leading QCD part are shown in Fig. 2 for 3 flavors. For the VMD part we can obtain the results from (2.39), simply replacing the factor ( $1-\mathrm{x}$ )/x by

$$
\begin{equation*}
\frac{\alpha_{\mathrm{em}}}{\pi} \ln \frac{s \theta_{\max }^{2}}{4 \mathrm{~m}_{\mathrm{e}}^{2}}\left[\frac{1}{\mathrm{x}}\left(\ln \frac{1}{\mathrm{x}}-\frac{7}{4}\right)+\frac{3}{2}+\ln \frac{1}{\mathrm{x}}+\frac{\mathrm{x}}{4}\right] \tag{2.43}
\end{equation*}
$$

## 3. PARTON CROSS SECTION

Now we calculate the parton cross sections which we need for our purpose. The kinematics are shown in Fig. 3 and the contributing diagrams are given in Fig. 4. We introduce the usual variables

$$
\begin{equation*}
x_{p}=\frac{Q^{2}}{2 p_{1} \cdot q}, \quad y=\frac{p_{1} \cdot q}{p_{1} \cdot k_{1}}, \quad z_{p}=\frac{p_{1} \cdot p_{2}}{p_{1} \cdot q}, \quad \phi, \quad p_{T} \tag{3.1}
\end{equation*}
$$

where $q=k_{1}^{-}-k_{2}, \quad Q^{2} \equiv-q^{2}$ and, as illustrated in Fig. 3, the azimutha1 angle $\phi$ and the transverse momentum $P_{T}$ are defined in the frame where $\overrightarrow{\mathrm{q}} \|_{\mathrm{p}_{1}}$. The results are ${ }^{20}$

$$
\begin{align*}
\frac{d \sigma_{i}}{d x_{p} d y d z_{p} d p_{T}^{2} d \phi}= & \alpha_{s}\left(Q^{2}\right) \frac{\alpha_{e m}^{2}}{2 \pi Q^{2} y} e_{q}^{2} \delta\left(p_{T}^{2}-\frac{Q^{2} z_{p}\left(1-z_{p}\right)\left(1-x_{p}\right)}{x_{p}}\right) \\
& \times c_{i}\left(A_{i}+B_{i} \cos \phi+C_{i} \cos 2 \phi\right) \tag{3.2}
\end{align*}
$$

where $e_{q}$ is the charge of the quark hit by the hard photon with momentum q. The suffix $i=a, b$ stands for the diagrams (al) $+(a 2),(b 1)+(b 2)$ of Fig. 4,

$$
c_{a}=c_{2}(R)=\frac{4}{3} \quad, \quad c_{b}=T(R)=\frac{1}{2}
$$

and $A_{i}, B_{i}$, and $C_{i}$ are given as follows: ${ }^{20}$

$$
\begin{align*}
& A_{a}=8(1-y) x_{p} z_{p}+\left[1+(1-y)^{2}\right]\left[\left(1-x_{p}\right)\left(1-z_{p}\right)+\frac{1+x_{p}^{2} z_{p}^{2}}{\left(1-x_{p}\right)\left(1-z_{p}\right)}\right]  \tag{3.3a}\\
& A_{b}=16(1-y) x_{p}\left(1-x_{p}\right)+\left[1+(1-y)^{2}\right]\left[x_{p}^{2}+\left(1-x_{p}\right)^{2}\right] \frac{z_{p}^{2}+\left(1-z_{p}\right)^{2}}{z_{p}\left(1-z_{p}\right)},  \tag{3.3b}\\
& B_{a}=-4(2-y)(1-y)^{\frac{1}{2}}\left[\frac{x_{p} z_{p}}{\left(1-x_{p}\right)\left(1-z_{p}\right)}\right]^{\frac{1}{2}}\left[x_{p} z_{p}+\left(1-x_{p}\right)\left(1-z_{p}\right)\right],  \tag{3.4a}\\
& B_{b}=-4(2-y)(1-y)^{\frac{1}{2}}\left[\frac{x_{p}\left(1-x_{p}\right)}{z_{p}\left(1-z_{p}\right)}\right]^{\frac{1}{2}}\left(1-2 x_{p}\right)\left(1-2 z_{p}\right)  \tag{3.4b}\\
& C_{a}=4(1-y) x_{p} z_{p}  \tag{3.5a}\\
& C_{b}=8(1-y) x_{p}\left(1-z_{p}\right) \tag{3.5b}
\end{align*}
$$

Replacing $a_{s}\left(Q^{2}\right)$ by $a_{e m} e_{q}^{2}$ and the color factor $C_{b}$ by $C_{c}=3$ in the formulae of Fig. 4b, we get the cross section for the diagrams Fig. 4 c with

$$
\begin{equation*}
A_{c}=A_{b} \quad, \quad B_{c}=B_{b} \quad, \quad C_{c}=C_{b} \tag{3.6}
\end{equation*}
$$

Since experimentally we are not yet in a position to distinguish quark jets from gluon jets nor from antiquark jets, we should find an alternative way of defining the direction of the hadron plane. Suppose we require $z_{p}$ to be larger than $1 / 2$. Then the sense of the direction of
the hadron plane is redefined in terms of the "more energetic jet" axis. With the definition (3.1) we have

$$
\begin{equation*}
\frac{p_{1} \cdot p_{3}}{p_{1} \cdot q}=1-z_{p} \tag{3.7}
\end{equation*}
$$

Then we introduce the following newly defined $z_{p}^{\prime}$ :

$$
\begin{equation*}
z_{p}^{\prime} \equiv \max \left\{\frac{p_{1} \cdot p_{2}}{p_{1} \cdot q}, \frac{p_{1} \cdot p_{3}}{p_{1} \cdot q}\right\}, \frac{1}{2}<z_{p}^{\prime}<1 \tag{3.8}
\end{equation*}
$$

The corresponding $B_{i}^{\prime}$ s are obtained from (3.4) by noting the sign change in the substitution $z_{p} \rightarrow I-z_{p}, \phi \rightarrow \pi+\phi:$

$$
\begin{align*}
& B_{a}^{\prime}=-4(2-y)(1-y)^{\frac{1}{2}}\left(\frac{x_{p}}{1-x_{p}}\right)^{\frac{1}{2}} x_{p}\left[\left(\frac{z_{p}^{\prime}}{1-z_{p}}\right)^{\frac{1}{2}} z_{p}^{\prime}-\left(\frac{1-z_{p}^{\prime}}{z_{p}^{\prime}}\right)^{\frac{1}{2}}\left(1-z_{p}^{\prime}\right)\right], \\
& B_{b}^{\prime}=-8(2-y)(1-y)^{\frac{1}{2}}\left[x_{p}\left(1-x_{p}\right)\right]^{\frac{1}{2}}\left(2 x_{p}-1\right)\left[\left(\frac{z_{p}^{\prime}}{1-z_{p}^{\prime}}\right)^{\frac{1}{2}}-\left(\frac{1-z_{p}^{\prime}}{z_{p}^{\prime}}\right)^{1 / 2}\right],
\end{align*}
$$

where $z_{p}^{\prime}$ is constrained to the region

$$
\begin{equation*}
\frac{1}{2}<z_{p}^{\prime}<1 \tag{3.9}
\end{equation*}
$$

It is to be noted here that $B_{a}$ and $B_{a}^{\prime}$ are always negative and that this fact is characteristic of the vector coupling of gluons. If we calculate them with scalar gluons, we get

$$
\begin{gather*}
B_{a, s c a l a r} \propto 2(2-y)(1-y)^{\frac{1}{2}}\left[\frac{x_{p} z_{p}}{\left(1-x_{p}\right)\left(1-z_{p}\right)}\right]^{\frac{1}{2}}\left[x_{p}\left(1-z_{p}\right)+\left(1-x_{p}\right) z_{p}\right],  \tag{3.10}\\
B_{a, \text { scalar }}^{\prime} \propto 2(2-y)(1-y)^{\frac{1}{2}}\left[x_{p}\left(1-x_{p}\right)\right]^{\frac{1}{2}}\left[\left(\frac{z_{p}^{\prime}}{1-z_{p}^{\prime}}\right)^{\frac{1}{2}} z_{p}^{\prime}-\left(\frac{1-z_{p}^{\prime}}{z_{p}^{\prime}}\right)^{\frac{1}{2}}\left(1-z_{p}^{\prime}\right)\right], \\
\left(\frac{1}{2}<z_{p}^{\prime}<1\right)
\end{gather*}
$$

$B_{a, s c a l a r}$ and $B_{a, s c a l a r}^{\prime}$ are always positive. It should be noted that the sum of direct terms (i.e., $|(a 1)|^{2}+|(a 2)|^{2}$ in Fig. 4a) has essentially the same structure in both cases of the scalar and the vector couplings, and the difference comes from the interference terms. This means that the negative definiteness of $B_{a}$ and $B_{a}^{\prime}$ is not at all a trivial kinematical result and that it is very important to observe it for the test of perturbative QCD.

The details of the above calculations are given in Appendix B. Finally we present the parton cross section with primordial $\mathrm{k}_{\mathrm{T}}$ in the framework of NPM: ${ }^{13}$

$$
\begin{align*}
\frac{d \sigma}{d x_{p} d y d z_{p} d p_{T}^{2} d \phi} & =\frac{\alpha_{e m}^{2} e_{q}^{2}}{Q^{2} y}\left[\left(1+2 \frac{k_{T}^{2}}{Q^{2}}\right)\left\{1+(1-y)^{2}\right\}+8(1-y) \frac{k_{T}^{2}}{Q^{2}}\right. \\
& \left.-4 \frac{k_{T}^{2}}{Q}(2-y)(1-y)^{\frac{1}{2}} \cos \phi+4 \frac{k_{T}^{2}}{Q^{2}}(1-y) \cos 2 \phi\right] \\
& \times \delta\left(1-x_{p}\right) \delta\left(1-z_{p}\right) \delta\left(p_{T}^{2}-k_{T}^{2}\right) . \tag{3.11}
\end{align*}
$$

4. AZIMUTHAL ASYMMETRIES

It is a straightforward problem of convolution to get the azimuthal asymmetry formulae for $\langle\cos \phi\rangle$ and $\langle\cos 2 \phi\rangle$. We regard partons as jets and measure $\phi$. with regard to "the more energetic jet," that is, the jet with the larger $z_{j e t}$. Thus the $z_{j e t}$ of "the more energetic jet" may be identified as the $z_{p}^{\prime}$ introduced by (3.8) in the previous section.

Since typical three jet events are expected to be rare in the $Q^{2}$ region where we have sufficient event number, some well-defined procedure should be used to determine the hadron plane and $\phi$ experimentally. The most natural one is as follows (see Fig. 5) :
(1) Choose a Lorentz frame where the virtual photon is parallel to the target electron (or positron), e.g. the C.M. frame of them.
(2) Determine the hadron $p l a n e$ so as to minimize the acoplanarity ${ }^{21}$ with respect to the outgoing hadrons under the condition that the chosen plane should include the axis of the virtual photon and the target electron (or positron).
(3) Divide the outgoing hadrons into two groups (jets) by another plane including the above axis and being perpendicular to the hadron plane.
(4) Calculate $z_{j e t}$ for each group as

$$
\begin{equation*}
z_{j e t}=\frac{P \cdot\left(\sum_{i} k^{(i)}\right)}{P \cdot q} \tag{4.1}
\end{equation*}
$$

where $P$ is the momentum of the target electron (or positron).
(5) Determine the angle $\phi$ between the lepton plane and the half of the hadron plane containing the group (jet) with the larger $z_{j e t}$.

We present the results for the electron structure functions with three flavors because the charm contribution is expected to be suppressed due to its large mass in most of the $Q^{2}$ range considered here. ${ }^{22}$ Even if we have the charm contribution at very large $Q^{2}$, its effect results in the increase of the cross sections, but does not affect very much the characteristics of the effective ratios of the cross sections such as $\langle\cos \phi\rangle$ and $\langle\cos 2 \phi\rangle$.

We calculate the azimuthal asymmetries with fixed $Q^{2}$ and $x_{H}$ at a given $s=(100 \mathrm{GeV})^{2}$, using the following formula:

$$
\begin{align*}
& \langle\cos \phi\rangle_{X_{H}}, Q^{2}=\left[\sum_{i} \int \mathrm{~d} \xi \mathrm{dx}_{\mathrm{p}} \mathrm{dz}{ }_{j e t} \mathrm{dp}_{\mathrm{T}}^{2} \mathrm{~d} \phi \cos \phi\right. \\
& \left.\times \frac{d \sigma_{i}}{d x_{p} d Q^{2} d z_{j e t} d p_{T}^{2} d \phi} f_{i e}\left(\xi, Q^{2}\right) \delta\left(x_{H}-\xi x_{p}\right)\right] / \frac{d \sigma(0)}{d x_{H} d Q^{2}} \tag{4.2}
\end{align*}
$$

where $d \sigma^{(0)}$ is the cross section in the leading order of $\ln Q^{2}$, and $i$ stnads for a parton ( $q, \bar{q}, G$ and $\gamma$ ). $f_{a e}(a=q, \bar{q}, G)$ was introduced by (2.42), whereas $f_{\gamma e}$ is equal to $d N / d x$ defined by (2.41) and contributes to the "direct photon" process which will be discussed later. The formula for $\langle\cos 2 \phi\rangle_{X_{H}}, Q^{2}$ can be obtained replacing $\cos \phi$ by $\cos 2 \phi$ in the above Eq. (4.2). We have used the relation

$$
\begin{equation*}
Q^{2}=x_{H} y s \tag{4.3}
\end{equation*}
$$

and put $\Lambda=500 \mathrm{MeV}$.
To compare our results with those of the naive parton model (NPM), we estimate the latter by assuming the following primodial $\mathrm{k}_{\mathrm{T}}$ distribution in the VMD part of the photon structure functions and using (3.11):

$$
\begin{equation*}
f\left(k_{T}\right) 2 \pi k_{T} d_{T}=\frac{1}{\pi\left\langle k_{T}^{2}\right\rangle} e^{-\left(k_{T}^{2} /\left\langle k_{T}^{2}\right\rangle\right)} 2 \pi k_{T} \mathrm{dk}_{T} \tag{4.4}
\end{equation*}
$$

There is no room for this kind of $k_{T}$ in the leading part of the photon structure functions which is proportional to $\ln Q^{2} / \Lambda^{2}$. For numerical purpose we take $\left\langle\mathrm{k}_{\mathrm{T}}^{2}\right\rangle=(400 \mathrm{MeV})^{2}$ as in Ref. $15 .{ }^{23}$

We remind you here that in the contributions to the azimuthal asymmetries there are the "direct photon" processes shown in Fig. 4c besides the perturbative QCD processes corresponding to Figs. 4a and 4b. The "direct photon" contributions turn out to be substantially large. There
are backgrounds when we want to detect the azimuthal asymmetries as a QCD effect. But we emphasize that these QED contributions are calculable without ambiguity and enter as a theoretically well-determined quantity. In fact, their experimental detection is itself an interesting problem. We should not forget that hadrons in a jet are expected to be distributed symmetrically around the jet axis with the average $\mathrm{p}_{\mathrm{T}}$ of about 300 MeV . This $\mathrm{p}_{\mathrm{T}}$ spread works to diminish the azimuthal asymmetries. The best method to take this effect into account is to perform the MonteCarlo simulation used in jet analyses, but here we simply adopt the $\mathrm{p}_{\mathrm{T}}$ cutoff method as a substitute for the elaborate Monte-Carlo simulation. We present the results with a simple $\mathrm{p}_{\mathrm{T}}$ cutoff of the jet momentum requiring $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$ as well as those without $\mathrm{p}_{\mathrm{T}}$ cutoff. We show the $X_{H}$ dependence of the azimuthal asymmetries for $Q^{2}=5 \mathrm{GeV}^{2}$, $25 \mathrm{GeV}^{2}$ in Figs. 6-11. The QCD as well as "direct photon" contributions to $\langle\cos \phi\rangle$ are sensitive to the $p_{T}$ cutoff (compare Figs. 6 and 7). This means that we must be very careful to make definite predictions. But the $\mathrm{p}_{\mathrm{T}}$ cutoff method seems to be a good alternative to the Monte-Carlo simulation and Fig. 7 may be compared with experiments.

Note that the characteristic features in the $x_{H}$ dependence and the relative importance between the QCD and "direct photon" contributions are not changed very much by the cutoff effect. Where $x_{H}$ is large the "direct photon" contribution is dominant, whereas at smaller $\mathrm{x}_{\mathrm{H}}$ it tends to be suppressed and we can clearly see the enhanced QCD effects. In particular around $\mathrm{x}_{\mathrm{H}} \simeq 0.2,\langle\cos \phi\rangle$ is overwhelmingly dominated by the QCD contribution.

To discriminate the QCD effect from the $k_{T}$ effect of NPM, the $Q^{2}$ dependence is helpful (see Fig. 8). QCD with $p_{T}$ cutoff predicts gradually increasing $|\langle\cos \phi\rangle|$ with $Q^{2}$ (though it is mainly due to the $p_{T}$ cutoff), whereas NPM with VMD predicts $|\langle\cos \phi\rangle|$ to decrease rapidly with increasing $Q^{2}$.

The asymmetry $\langle\cos 2 \phi\rangle$ arises predominantly from the "direct photon" contribution and is insensitive to $\mathrm{p}_{\mathrm{T}}$ cutoff (compare Figs. 9 and 10). Thus its absolute value is a reliable prediction. For the reasons stated before the values with $\mathrm{P}_{\mathrm{T}}$ cutoff (i.e., Fig. 10) are to be more realistic. $\langle\cos 2 \phi\rangle$ has little to do with QCD test, but it is certainly worthwhile comparing experimental results with our calculations since it will verify the "direct photon" coupling very clearly. Its $Q^{2}$ dependence with a fixed $\mathrm{x}_{\mathrm{H}}=0.2$ is shown in Fig. 11 .

The cross sections are shown in Figs. 12 and 13.
There might be disturbances to azimuthal asymmetries due to fluctuation of parton $k_{T}$ as in Drell-Yan processes ${ }^{24}$ which appears to be caused by soft gluon bremsstrahlung. If there should be these disturbances, our result for $\langle\cos \phi\rangle$ would be changed. ( $\langle\cos 2 \phi\rangle$ would not change becuase it came mainly from the "direct photon" contribution.) But even if these effects were contributing, we could get rid of them by changing the experimențal determination of $\phi$. We suggest to determine the hadron plane disregarding the momentum axis of the virtual photon and the target electron (or positron). A possible choice of $\phi$ is the following:
(1) In the frame where $q^{0}=0$ and $\vec{q} \| \vec{p}$ (= momentum of the target electron or positron), select those hadrons of momentum $p$ which satisfies the condition $\vec{p} \cdot \vec{q}>0$ (which means "not emitted in the forward hemisphere of the target").
(2) Define $P_{\text {sum }} \equiv \sum_{i} p^{(i)}$ where the summation is over all hadrons selected in (1).
(3) In the frame with $q^{\circ}=0$ and $\vec{q} \| \vec{P}$ sum (not $\vec{P}$ ), determine $\phi$ following the same procedure as that suggested previously, but replacing $P$ by $\mathrm{P}^{\prime}=\left(\left|\overrightarrow{\mathrm{P}}_{\text {sum }}\right|,-\overrightarrow{\mathrm{P}}_{\text {sum }}\right)$ in (4.1).
This method is related to the following calculational constraints of $x_{p}>\frac{1}{2}$ and $z_{p}^{\prime}<x_{p}$ in the previous calculations. That is, only those events satisfying these constraints contribute to the azimuthal asymmetries of the new $\phi$.

Another merit of the above definition of $\phi$ is that we can single out as the pure "direct photon" events satisfying the conditions $x_{p}>\frac{1}{2}$ and $z_{p}^{\prime}<x_{p}$ those events without any jets in the forward hemisphere of the target electron (or positron). We call those events accompanying a forward jet "the QCD events." (Actually this class of events contains some "direct photon" events which are not counted in the above selection.) We could measure the angular asymmetries of each category of events independently. In the "direct photon" events $P$ ' will be parallel to $P$ in almost all events because the characteristic value of $\mathrm{k}_{\mathrm{T}}$ of the target virtual photon is of the order of electron mass. So we can safely use $P$ instead of the elaborately defined $P^{\prime}$.

In the following we present our results for the azimuthal asymmetries with respect to the newly defined $\phi$. We show the results without $p_{T}$ cutoff in Fig. 14 and those with $\mathrm{p}_{\mathrm{T}}$ cutoff requiring $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$ in Fig. 15. 〈 $\cos 2 \phi\rangle$ of "the QCD events" may be too small to be detected.〈 $\cos \phi\rangle$ is again sensitive to $P_{T}$ cutoff and that of "the QCD events" after the cutoff is small as shown in Fig. 15. (If the effective $\mathrm{p}_{\mathrm{T}}$
cutoff due to the hadronization is to be smaller, it will of course be more enhanced.) For the "direct photon" events both 〈cos $\phi\rangle$ and $\langle\cos 2 \phi\rangle$ seem to be large enough for their detection. (The increase of $\langle\cos 2 \phi\rangle$ after the $p_{T}$ cutoff is due to the drop of the direct photon cross section with $\mathrm{P}_{\mathrm{T}}$ cutoff and is somewhat artificial.)

The $Q^{2}$ dependence of the azimuthal asymmetries is shown in Figs. 16 and 17 for various cases.

The cross sections for the "direct photon" events are shown in Fig. 18.

## 5. CONCLUSIONS AND REMARKS

The photon structure functions are studied in the framework of Curci, Furmanski and Petronzio. A focus is given on the renormalization mechanism of the collinear mass singularities in the case of the target photon. The electron structure functions can be studied on equal footing due to the equivalent photon approximation.

Then the azimuthal asymmetries in the deep inelastic $e^{+} e^{-}$scattering are investigated. The detailed results are shown in Figs. 6-11. 〈cos $\phi\rangle$ is large but expected to be diminished considerably in hadronization processes. We take this effect into account phenomenologically by requiring the $\mathrm{p}_{\mathrm{T}}$ cutoff of $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$. The signals and characteristics of $\langle\cos \phi\rangle$ seems to be enough to be detected. Its $Q^{2}$ dependence will be helpful to distinguish QCD from NPM. $\langle\cos 2 \phi\rangle$ is large and expected not to be diminished much in hadronization processes. It serves as a very good test for the "direct photon" contributions in the photon deep inelastic scattering.

The method is suggested to get rid of possible backgrounds due to parton $k_{T}$ from soft gluon emission or from any other mechanism. In this method 〈cos $\phi\rangle$ of "the QCD events" is diminished and seems difficult to detect. Their $\langle\cos 2 \phi\rangle$ detection is likely to be harder. On the other hand, $\langle\cos \phi\rangle$ and $\langle\cos 2 \phi\rangle$ of the "direct photon" events (i.e., events with no forward jet of the target electron or positron) turn out to be large and we conclude that they can provide clean signals for the "direct photon" process.

Finally we remark that the higher order corrections and the inclusion of charm quark effects are left as future problems.

## ACKNOWLEDGEMENTS

One of the authors (A.H.) wishes to thank K. I. Aoki for discussions and comments. Another author (J.K.) is grateful to the Theory Group at SLAC for their kind hospitality. This work was supported in part by the Department of Energy under contract DE-AC03-76SF00515 and by the Japn Society for the Promotion of Science through the Joint Japan-U.S. Collaboration in High Einergy Physics.

## APPENDIX A

## ANOMALOUS DIMENSIONS

We list the expressions for the anomalous dimensions which appeared in the text:

$$
\begin{aligned}
& d_{N}^{N S}=\frac{C_{2}(R)}{\beta_{0}}\left[1-\frac{2}{N(N+1)}+4 \sum_{\ell=2}^{\infty}\left(\frac{1}{\ell}-\frac{1}{\ell+N-1}\right)\right] \\
& d_{N}^{q G}=\frac{4 T(R)}{\beta_{0}} \frac{2+N+N^{2}}{N(N+1)(N+2)} \\
& d_{N}^{G q}=\frac{2 C_{2}(R)}{\beta_{0}} \frac{2+N+N^{2}}{N\left(N^{2}-1\right)} \\
& d_{N}^{G G}=\frac{C_{2}(G)}{\beta_{0}}\left[\frac{1}{3}-\frac{4}{N(N-1)}-\frac{4}{(N+1)(N+2)}+4 \sum_{\ell=2}^{\infty}\left(\frac{1}{\ell}-\frac{1}{\ell+N-1}\right)+\frac{4 T(R)}{3 C_{2}(R)}\right], \\
& d_{N}^{q Y}=\frac{2+N+N^{2}}{N(N+1)(N+2)} \\
& d_{N}^{ \pm}=\frac{1}{2}\left[\left(d_{N}^{N S}+d_{N}^{G G}\right) \pm \sqrt{\left.\left(d_{N}^{N S}-d_{N}^{G G}\right)^{2}+d_{N}^{q G} d_{N}^{G q}\right]}\right.
\end{aligned}
$$

where

$$
\beta_{0}=\frac{11}{3} C_{2}(G)-\frac{4}{3} T(R)
$$

and

$$
C_{2}(R)=\frac{N^{2}-1}{2 N}, \quad T(R)=\frac{f}{2}, \quad C_{2}(G)=N
$$

for $\operatorname{SU}(\mathbb{N})$ color gauge group with $f$ flavors.

## APPENDIX B

## CALCULATION OF PARTON CROSS SECTIONS

The calculation is most easily done in the frame where $q^{\circ}=0$ and $\overrightarrow{\mathrm{q}} \| \overrightarrow{\mathrm{p}}_{1}$.

We define the unit vectors in this frame as follows:

$$
\varepsilon_{L}^{\mu}=\frac{\bar{q}^{\mu}}{|\vec{q}|}, \quad \varepsilon_{0}^{\mu}=(1,0,0,0), \quad \varepsilon_{T}^{\mu}=\frac{\bar{k}_{1}^{\mu}+\bar{k}_{2}^{\mu}}{\left|\vec{k}_{1}+\vec{k}_{2}\right|}
$$

and

$$
\begin{equation*}
\varepsilon_{s} \cdot \varepsilon_{i}=0, \quad \varepsilon_{s}^{2}=-1 \quad(i=0, T, L) \tag{B.1}
\end{equation*}
$$

with

$$
\begin{equation*}
\vec{q}^{\mu}=(0, \overrightarrow{\mathrm{q}}), \quad \overline{\mathrm{k}}_{1}^{\mu}+\overline{\mathrm{k}}_{2}^{\mu}=\left(0, \overrightarrow{\mathrm{k}}_{1}+\overrightarrow{\mathrm{k}}_{2}\right) \tag{B.2}
\end{equation*}
$$

Defining the leptonic tensor

$$
\begin{equation*}
\left\langle L^{\mu \nu}\right\rangle_{\text {spin }}=\frac{1}{2} \operatorname{Tr}\left(k_{1} \gamma^{\mu} k_{2} \gamma^{\nu}\right) \tag{B.3}
\end{equation*}
$$

we find

$$
\begin{gather*}
\frac{\left\langle L^{\mu \nu}\right\rangle_{\text {spin }}}{Q^{2}}=\frac{4(1-y)}{y^{2}} \varepsilon_{0}^{\mu} \varepsilon_{0}^{\nu}+\frac{1+(1-y)^{2}}{y^{2}}\left(\varepsilon_{T}^{\mu} \varepsilon_{T}^{\nu}+\varepsilon_{S}^{\mu} \varepsilon_{S}^{\nu}\right) \\
+\frac{2(2-y)(1-y)^{\frac{1}{2}}}{y^{2}}\left(\varepsilon_{0}^{\mu} \varepsilon_{T}^{\nu}+\varepsilon_{T}^{\mu} \varepsilon_{0}^{\nu}\right)+\frac{2(1-y)}{y^{2}}\left(\varepsilon_{T}^{\mu} \varepsilon_{T}^{\nu}-\varepsilon_{S}^{\mu} \varepsilon_{S}^{\nu}\right) . \tag{B.4}
\end{gather*}
$$

We define the hadronic tensor

$$
\begin{equation*}
\left\langle W_{\mu v}\right\rangle_{\operatorname{spin}}=\left\langle p_{1}\right| J_{\mu}(0)\left|p_{2}, p_{3}\right\rangle\left\langle p_{2}, p_{3}\right| J_{v}(0)\left|p_{1}\right\rangle \tag{B.5}
\end{equation*}
$$

with the normalization

$$
\begin{equation*}
\left\langle p \mid p^{\prime}\right\rangle=(2 \pi)^{3} 2 p^{0} \delta^{3}\left(\vec{p}-\vec{p}^{\prime}\right) \tag{B.6}
\end{equation*}
$$

The cross section is then given by

$$
\begin{align*}
d \sigma= & \frac{1}{4 p_{1}^{\cdot} k_{1}} \frac{d^{3} k_{2}}{(2 \pi)^{3} 2 k_{2}^{o}} \frac{d^{3} p_{2}}{(2 \pi)^{3} 2 p_{2}^{o}} \frac{d^{3} p_{3}}{(2 \pi)^{3} 2 p_{3}^{o}} \frac{(4 \pi \alpha e m)^{2} e_{q}^{2}}{Q^{4}} \\
& \times\left\langle L^{\mu \nu}\right\rangle_{\operatorname{spin}}\left\langle W_{\mu \nu}\right\rangle_{\operatorname{spin}}(2 \pi)^{4} \delta^{4}\left(k_{1}+p_{1}-k_{2}-p_{2}-p_{3}\right) \\
= & \frac{1}{4 p_{1} \cdot k_{1}} \frac{d^{3} k_{2}}{(2 \pi)^{3} 2 k_{2}^{o}} \frac{d^{3} p_{2}}{(2 \pi)^{3} 2 p_{2}^{o}} \frac{(4 \pi \alpha}{e m)^{2} e_{q}^{2}} \\
Q^{2} & \left\langle L^{\mu \nu}\right\rangle_{\operatorname{spin}}^{Q^{2}}\left\langle W_{\mu \nu}\right\rangle \operatorname{spin}  \tag{B.7}\\
& \times\left.(2 \pi) \delta^{+}\left(\left(p_{1}+q-p_{2}\right)^{2}\right)\right|_{q=} k_{1}-k_{2}
\end{align*}
$$

Since we have

$$
\begin{align*}
\delta^{+}\left(\left(p_{1}+q-p_{2}\right)^{2}\right) & =z_{p} \delta\left(p_{T}^{2}-\frac{z_{p}}{x_{p}}\left(1-x_{p}\right)\left(1-z_{p}\right) Q^{2}\right),  \tag{B.8}\\
\frac{d^{3} p_{2}}{(2 \pi)^{3} 2 p_{2}^{o}} & =\frac{d p_{T}^{2} d z_{p} d \phi}{(2 \pi)^{3} 4 z_{p}}  \tag{B.9}\\
\frac{d^{3} k_{2}}{(2 \pi)^{3} 2 k_{2}^{0}} & =\pi p_{1} \cdot k_{1} \frac{y d y d x_{p}}{(2 \pi)^{3}} \tag{B.10}
\end{align*}
$$

we finally obtain

$$
\begin{align*}
\frac{-d \sigma}{d x_{p} d y d z_{p} d p_{T}^{2} d \phi}= & \frac{\alpha_{e m}^{2} e^{2}}{32 \pi^{2}} \frac{y}{Q^{2}} \frac{\left\langle L^{\mu \nu}\right\rangle_{\text {spin }}}{Q^{2}}\left\langle W_{\mu \nu}\right\rangle_{\text {spin }} \\
& \times \delta\left(p_{T}^{2}-\frac{z_{p}}{x_{p}}\left(1-x_{p}\right)\left(1-z_{p}\right) Q^{2}\right) . \tag{B.11}
\end{align*}
$$

When the initial parton is a quark, we find

$$
\begin{align*}
&\left\langle W^{\mu \nu}\right\rangle \\
& \text { spin }=g_{s}^{2}\left(Q^{2}\right) C_{2}(R) \frac{-2 q^{2}}{\left(p_{1} \cdot p_{3}\right)\left(p_{2} \cdot p_{3}\right)}\left[\left(p_{1}^{\mu}-\frac{p_{1}^{\cdot} q}{q^{2}} q^{\mu}\right)\left(p_{1}^{\nu}-\frac{p_{1} \cdot q}{q^{2}} q^{\nu}\right)\right. \\
&\left.+\left(p_{1} \leftrightarrow p_{2}\right)+\frac{\left(p_{1} \cdot q\right)^{2}+\left(p_{2} \cdot q\right)^{2}}{q^{2}}\left(g^{\mu \nu}-\frac{q^{\mu} q^{\nu}}{q^{2}}\right)\right] \\
&=4 \pi \alpha_{s}\left(Q^{2}\right) c_{2}(R) \frac{4 x_{p}}{\left(1-x_{p}\right)\left(1-z_{p}\right)}\left[2 x_{p} \frac{p_{1}^{\mu} p_{1}^{\nu}+p_{2}^{\mu} p_{2}^{\nu}}{Q^{2}}\right.  \tag{B.12}\\
&\left.-\frac{2 x_{p} z_{p}+\left(1-z_{p}\right)^{2}+\left(1-x_{p}\right)^{2}}{2 x_{p}} g^{\mu \nu}+\left(\text { terms proportional to } q^{\mu}, q^{\nu}\right)\right] .
\end{align*}
$$

For a gluon as the initial parton, we have

$$
\begin{align*}
\left\langle W^{\mu \nu}\right\rangle_{\text {spin }}^{G} & =g_{s}^{2}\left(Q^{2}\right) T(R) \frac{-2 q^{2}}{\left(p_{1} \cdot p_{2}\right)\left(p_{1} \cdot p_{3}\right)}\left[\left(p_{2}^{\mu}-\frac{p_{2} \cdot q}{q^{2}} q^{\mu}\right)\left(p_{2}^{\nu}-\frac{p_{2} \cdot q}{q^{2}} q^{\nu}\right)\right. \\
& \left.+\left(p_{2} \leftrightarrow p_{3}\right)+\frac{\left(p_{2} \cdot q\right)^{2}+\left(p_{3} \cdot q\right)^{2}}{q^{2}}\left(g^{\mu \nu}-\frac{q^{\mu} q^{\nu}}{q^{2}}\right)\right] \\
& =4 \pi \alpha_{s}\left(Q^{2}\right) T(R) \frac{4 x_{p}}{z_{p}\left(1-z_{p}\right)}\left[2 x_{p} \frac{p_{2}^{\mu} p_{2}^{\nu}+p_{3}^{\mu} p_{3}^{\nu}}{Q^{2}}\right. \\
& \left.\left.-\frac{1-2\left(z_{p}\left(1-z_{p}\right)+x_{p}\left(1-x_{p}\right)\right)}{2 x_{p}} g^{\mu \nu}+\text { (terms proportional to } q^{\mu}, q^{\nu}\right)\right] . \tag{B.13}
\end{align*}
$$

Using the relations

$$
\begin{align*}
p_{2}^{\mu} & =\frac{Q}{2 x_{p}}\left[\left(1-x_{p}\right)\left(1-z_{p}\right)+x_{p} z_{p}\right] \varepsilon_{0}^{\mu}+\frac{Q}{2}\left(1-\frac{1-z_{p}}{x_{p}}\right) \varepsilon_{L}^{\mu} \\
& +Q\left[\frac{z_{p}}{x_{p}}\left(1-z_{p}\right)\left(1-x_{p}\right)\right]^{\frac{1}{2}} \cos \phi \varepsilon_{T}^{\mu} \\
& +Q\left[\frac{z_{p}}{x_{p}}\left(1-z_{p}\right)\left(1-x_{p}\right)\right]^{\frac{1}{2}} \sin \phi \varepsilon_{s}^{\mu} \tag{B.14}
\end{align*}
$$

$$
\begin{align*}
p_{3}^{\mu} & =\frac{Q}{2 x_{p}}\left[x_{p}\left(1-z_{p}\right)+z_{p}\left(1-x_{p}\right)\right] \varepsilon_{0}^{\mu}+\frac{Q}{2}\left(1-\frac{z_{p}}{x_{p}}\right) \varepsilon_{L}^{\mu} \\
& -Q\left[\frac{z_{p}}{x_{p}}\left(1-z_{p}\right)\left(1-x_{p}\right)\right]^{\frac{1}{2}} \cos \phi \varepsilon_{T}^{\mu} \\
& -Q\left[\frac{z_{p}}{x_{p}}\left(1-z_{p}\right)\left(1-x_{p}\right)\right]^{\frac{1}{2}} \sin \phi \varepsilon_{S}^{\mu} \tag{B.15}
\end{align*}
$$

we obtain the formulae in Sect. 3.
If we calculate with scalar gluons, (B.12) becomes

$$
\begin{align*}
\left\langle W^{\mu \nu}\right\rangle_{\text {spin }}^{\text {scalar }} & \propto g^{2} \frac{-q^{2}}{\left(p_{1} \cdot p_{3}\right)\left(p_{2} \cdot p_{3}\right)}\left[\left(p_{3}^{\mu}-\frac{p_{3} \cdot q}{q^{2}} q^{\mu}\right)\left(p_{3}^{\nu}-\frac{p_{3} \cdot q}{q^{2}} q^{\nu}\right)\right. \\
& \left.+\frac{\left(p_{3} \cdot q\right)^{2}}{q^{2}}\left(g^{\mu \nu}-\frac{q^{\mu} q^{\nu}}{q^{2}}\right)\right] \\
& \propto g^{2} \frac{2 x_{p}}{\left(1-x_{p}\right)\left(1-z_{p}\right)}\left[2 x_{p} \frac{p_{3}^{\mu} p_{3}^{\nu}}{q^{2}}-\frac{\left(z_{p}-x_{p}\right)^{2}}{2 x_{p}} g^{\mu \nu}\right. \\
& \left.+\left(\text { terms proportional to } q^{\mu}, q^{\nu}\right)\right] \tag{B.16}
\end{align*}
$$

## FIGURE CAPTIONS

1. The photon structure functions with three quark flavors.
2. The electron structure functions with three quark flavors.
3. Kinematics, $k_{1}$ and $k_{2}$ are the momenta for incident and outgoing electrons which couple to the virtual photon. $p_{1}$ is the momentum of the incident parton. $\mathrm{p}_{2}$ and $\mathrm{p}_{3}$ are the momenta of the scattered partons.
4. The Feynman graphs for parton cross sections.
(a) Electron-quark scattering.
(b) Electron-gluon scattering.
(c) Electron-photon scattering.
5. The experimental determination of $\phi$.
6. The $x_{H}$-dependence of $\langle\cos \phi\rangle$ without $p_{T}$ cutoff.
(1) $Q C D$.
(2) NPM with $\left\langle\mathrm{k}_{\mathrm{T}}^{2}\right\rangle=(400 \mathrm{MeV})^{2}$.
(3) (1) + "direct photon".
(4) (2) + "direct photon".
7. The $\mathrm{x}_{\mathrm{H}}$-dependence of $\langle\cos \phi\rangle$ with the condition $\mathrm{P}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
(1) $Q C D$.
(2) NPM with $\left\langle\mathrm{k}_{\mathrm{T}}^{2}\right\rangle=(400 \mathrm{MeV})^{2}$.
(3) (1) + "direct photon".
(4) (2) + "direct photon".
8. The $Q^{2}$-dependence of $\langle\cos \phi\rangle$ at $x_{H}=0.2$.
(1) $Q C D+$ "direct photon" without $p_{T}$ cutoff.
(2) NPM + "direct photon" without $\mathrm{P}_{\mathrm{T}}$ cutoff.
(3) QCD + "direct photon" with $\mathrm{P}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
(4) NPM + "direct photon" with $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
9. The $\mathrm{x}_{\mathrm{H}}$-dependence of $\langle\cos 2 \phi\rangle$ without $\mathrm{p}_{\mathrm{T}}$ cutoff.
(1) QCD.
(2) NPM with $\left\langle\mathrm{k}_{\mathrm{T}}^{2}\right\rangle=(400 \mathrm{MeV})^{2}$.
(3) (1) + "direct photon".
(4) (2) + "direct photon".
10. The $\mathrm{x}_{\mathrm{H}}$-dependence of $\langle\cos 2 \phi\rangle$ with the condition $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
(1) QCD.
(2) NPM with $\left\langle\mathrm{k}_{\mathrm{T}}^{2}\right\rangle=(400 \mathrm{MeV})^{2}$.
(3) (1) + "direct photon".
(4) (2) + "direct photon".
11. The $Q^{2}$-dependence of $\langle\cos 2 \phi\rangle$ at $X_{H}=0.2$.
(1) QCD + "direct photon", without $p_{T}$ cutoff.
(2) QCD + "direct photon" with $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
12. The $\mathrm{x}_{\mathrm{H}}$-dependence of the total cross section for electron deep inelastic scattering ( $\sqrt{s}=100 \mathrm{GeV}$ ).
13. The $Q^{2}$-dependence of the total corss section for electron deep inelastic scattering ( $\sqrt{\mathrm{s}}=100 \mathrm{GeV}$ ).
14. The $\mathrm{x}_{\mathrm{H}}$-dependence of the azimuthal asymmetries with the improved definition of $\phi$ (without $p_{T}$ cutoff). As to the "direct photon" events, the result is almost $Q^{2}$-independent.
15. The $X_{H}$-dependence of the azimuthal asymmetries with the improved definition of $\phi$ (with the condition $p_{T} \geq 300 \mathrm{MeV}$ ).
16. The $Q^{2}$-dependence of the aximuthal asymmetries for the "QCD events" ( $\mathrm{x}_{\mathrm{H}}=0.2$ ). Broken line: without $\mathrm{p}_{\mathrm{T}}$ cutoff. Solid line: with $\mathrm{P}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
17. The $Q^{2}$-dependence of the azimuthal asymmetries for the "direct photon" events ( $\mathrm{x}_{\mathrm{H}}=0.2$ ). Broken line: without $\mathrm{p}_{\mathrm{T}}$ cutoff. Solid line: with $\mathrm{P}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
18. The $\mathrm{x}_{\mathrm{H}}$-dependence of the cross section for the "direct photon" events. Broken line: without $\mathrm{p}_{\mathrm{T}}$ cutoff. Solid Line: with $\mathrm{p}_{\mathrm{T}} \geq 300 \mathrm{MeV}$.
