Longitudinal  $e^-$  Beam Polarization  
Asymmetry in  $e^+e^- \rightarrow \text{Hadrons}^*$

## ABSTRACT

We introduce and analyze the longitudinal polarization asymmetry of the process  $e^+e^- \rightarrow \text{hadrons}$  with longitudinally polarized electron beams on and near the  $Z_0$  resonance. We show that, in spite of the intrinsic strong interaction presence in the final state, the vast majority of the diagrams which contribute to one electroweak loop are free of strong interaction effects. Further, on  $Z^0$  resonance it is independent of the final states giving a commensurate increase in statistics. We show that for this reason the total theoretical strong interaction uncertainty on  $Z^0$  resonance  $\Delta A_{LR}^{e^+e^- \rightarrow \text{hadrons}} \leq 0.01$  allowing a measurement of  $A_{LR}$  to  $\pm 0.02$  which can be interpreted as a measurement of  $\sin^2 \theta_W$  to  $\pm 0.003$ ) with only  $\sim 5 \times 10^4$   $Z^0$ 's. This rather peculiar property of the asymmetry could allow SLC/LEP experiments to test the standard GSW theory and possible new physics beyond GSW early in the lifetime of these accelerators.

## 1. Introduction

In the next few years, a number of high precision experiments will be carried out which will test electroweak theories at the one loop level in analogy with experiments which, years ago, probed QED. These include neutrino-electron scattering by the CHARM II collaboration and LEP and SLC measurements of  $e^+e^-$  annihilation.

In this paper we shall focus our attention on the peculiar properties of one specific experiment which will be performed in the near future at SLC (and, perhaps, at LEP) and which, we believe, deserves some rather special treatment: the measurement of the longitudinal polarization asymmetry in the collision of an unpolarized positron with a longitudinally polarized electron on and near the  $Z^0$  resonance. This process has already been discussed in detail in the case of production of a final  $\mu^+\mu^-$  pair and it has been shown<sup>1</sup> that it can represent a very precise test of both the Glashow-Salam-Weinberg (GSW) electroweak theory<sup>2</sup> at the one loop level and of possible New Physics beyond GSW. This is because radiative corrections to one loop are particularly sensitive to the existence of new heavy particles (in the 100-1000 GeV range) which do not decouple and/or of new gauge bosons—such as a new heavy  $Z'$  in the 300-1000 GeV region,<sup>3</sup> with substantial mixing with  $Z^0$ .<sup>‡1</sup>

One problem with this beautiful program is statistics. Roughly  $\sim 10^6$   $Z'$ 's must be produced to achieve a  $\sim 1\%$  experimental accuracy corresponding to  $\sim 3 \times 10^4$   $\mu^+\mu^-$  pairs, a luminosity available only at mature SLC or LEP.

---

<sup>‡1</sup> The *same* tests could be achieved by measuring the  $\tau$  polarization in the process  $e^+e^- \rightarrow \tau^+\tau^-$  e.g. at LEP.

An obvious solution to this problem would be to use final state hadrons with a commensurate increase in the statistics factor of around 30. The price to pay is that final state strong interactions introduce uncertainties in the theoretical predictions. We show below though that  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  is to high accuracy quite insensitive to strong interactions. Their effects are cancelled out by the special properties of the longitudinal polarization asymmetry. This is in contradistinction to other possible asymmetries with final hadrons such as forward/backward and transverse asymmetries  $A_{FB}$  and  $A_{\perp}$ , where not only are the strong interaction effects not cancelled, but the difficulties in the precise definition of jet axes make precise definitions of such asymmetries less clear.<sup>4</sup> Specifically, we will show that to lowest order in  $\alpha_{em}$ ,  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  on  $Z^0$  resonance is not only independent of the identity of the final states but is also unaffected by strong interactions. This is true whether or not one uses perturbative QCD. Thus, the subsequent hadronization of the final state quarks (liable to be a major source of strong interaction uncertainty for other experiments) does not affect  $A_{LR}$  on resonance!

Off  $Z^0$  resonance, the asymmetry becomes weak flavor dependent. However, assuming that perturbative QCD can be used, as e.g. with  $udscb$  quarks,  $A_{LR}$  is still independent of strong interactions, at least through order  $\alpha_s$ . This means that off resonance (only) top quark production has to be studied separately.

Including electroweak corrections to one loop, the situation described above remains substantially unchanged for the vast majority of such contributions, particularly on  $Z^0$  resonance. We show this below and isolate those diagrams which might introduce substantial strong interaction uncertainties. We will give arguments for why these diagrams should give negligible strong interaction uncer-

tainty, i.e. at worst of order  $\alpha_{em} \cdot \alpha_{strong}$ . Thus, we should be able to interpret theoretically  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  to better than 1% and make use of all final states at LEP/SLC to explore GSW and beyond at the one electroweak loop level. We show that the increase in statistics allows an experimental measurement of the weak-mixing angle  $\sin^2 \theta_w$  to  $\pm 0.003$  via  $A_{LR}$  with only  $5 \times 10^4 Z$ 's (early in the SLC/LEP lifetimes).

## 2. $A_{LR}$ on Resonance

We start with some definitions.  $A_{LR}^{e^+e^- \rightarrow f\bar{f}}$  defined with 100% polarization is equal to ( $f \neq e^-, \nu_e$ ):

$$A_{LR}^{e^+e^- \rightarrow f\bar{f}} = \frac{\sigma_{e_L^- e^+ \rightarrow f\bar{f}} - \sigma_{e_R^- e^+ \rightarrow f\bar{f}}}{\sigma_{e_L^- e^+ \rightarrow f\bar{f}} + \sigma_{e_R^- e^+ \rightarrow f\bar{f}}}. \quad (2.1)$$

We will consider the asymmetry with polarization  $P = 100\%$  for pedagogical reasons but it is easy to put in arbitrary polarization  $P$ . Then  $A_{LR}^{e^+e^-(P) \rightarrow f\bar{f}} = -PA_{LR}^{e^+e^-(P=-1) \rightarrow f\bar{f}}$ . Indeed, when discussing the analyzing power of the polarization asymmetry in Section 5 including the strong interaction uncertainty and experimental systematic and statistical errors we will use  $P = 40\%$ . We define the  $Z_0$  coupling as in Fig. 1 and assuming only  $Z^0$  exchange to be important on resonance, we have to lowest order in  $\alpha_{em}$

$$A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-} = \frac{g_{Le}^2 - g_{Re}^2}{g_{Le}^2 + g_{Re}^2} \quad (2.2)$$

which depends only on the initial state. The differential cross section for  $e^+e^- \rightarrow f\bar{f}$  in free field theory including only  $Z^0$  exchange is ( $s, t, u$  are the usual Man-

delstam variables):

$$\begin{aligned} \frac{d\sigma}{d\Omega} \sim & (g_L^2 + g_R^2)_e (g_L^2 + g_R^2)_f \frac{(u^2 + t^2)}{s^2} \\ & + (g_L^2 - g_R^2)_e (g_L^2 - g_R^2)_f \frac{(u^2 - t^2)}{s^2} \end{aligned} \quad (2.3)$$

In the presence of strong interactions

$$\begin{aligned} \frac{u^2 + t^2}{s^2} & \longrightarrow \text{Sym}(\cos \theta, f) \\ \frac{u^2 - t^2}{s^2} & \longrightarrow \text{Anti}(\cos \theta, f) \end{aligned} \quad (2.4)$$

where Sym(Anti) is symmetric (anti-symmetric) in  $\cos \theta \rightarrow -\cos \theta$  with  $\theta$  the angle within the detector with respect to the electron beam direction. Sym and Anti may be flavor dependent (as for example with heavy top production) and when final state hadronization is included can be very complicated (and even unknown) functions. Integrating  $d\sigma/d\Omega$  symmetrically from  $\cos \theta = -x$  to  $\cos \theta = +x$  e.g. around a line perpendicular to the  $e^-$  beam axis

$$\int_0^{2\pi} d\phi \int_{-x}^{+x} d\cos \theta \frac{d\sigma}{d\Omega} = (g_L^2 + g_R^2)_e I(x, f) \cdot (\text{constant}) \quad (2.5)$$

where

$$I(x, f) = \int_0^{2\pi} d\phi \int_{-x}^{+x} d\cos \theta (g_L^2 + g_R^2)_f \text{Sym}(\cos \theta, f) \quad (2.6)$$

since

$$\int_0^{2\pi} d\phi \int_{-x}^x d\cos \theta \text{Anti}(\cos \theta, f) = 0. \quad (2.7)$$

Note that after hadronization  $f\bar{f} \rightarrow \text{hadrons}$   $I(x, f)$  can become an arbitrarily

horrible flavor dependent function *but it is cancelled in  $A_{LR}$  on  $Z^0$  resonance.*

$$A_{LR}^{e^+e^- \rightarrow f\bar{f}}(-M_Z^2) = \frac{(g_L^2 - g_R^2)_e I(x, f)}{(g_L^2 + g_R^2)_e I(x, f)} = \frac{(g_L^2 - g_R^2)_e}{(g_L^2 + g_R^2)_e} = A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2). \quad (2.8)$$

Clearly, this argument holds for any combination of final state data,  $e^+e^- \rightarrow$  hadrons,  $\tau^+\tau^-$ ,  $\mu^+\mu^- \dots$  as long as we are careful to remain on pole and exclude final states with  $t$  channels such as  $e^+e^-$ .

Note that all dependence on the final flavor and the strong interaction effects in the final state hadronization have cancelled in the ratio, *due to symmetric integration.* Note further that this symmetric integration is over an angle  $\theta$  defined in the *detector*. We have not needed to define jet axes in order to integrate. We simply sum all hadronic data in a region of the detector (depicted in Fig. 2) defined by the  $e^-$  beam direction for left-handed and right-handed initial state electrons.

There is a very simple heuristic argument for the independence of  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  on  $Z^0$  resonance of the details of the final states. We produce  $Z^0$ 's with  $e_L^-$  at some rate and they decay. We then produce  $Z^0$ 's with  $e_R^-$  at a *different* rate and they decay. In the ratio  $A_{LR}$ , the decay rate of the  $Z^0$  cancels because we have manipulated only the *initial* state.

Strictly speaking, our result, Eq. (2.8), is true to the extent to which one can neglect, on  $Z_0$  resonance, contributions not due to pure  $Z_0$  exchange. Although one knows such terms to be suppressed by small  $\sim \Gamma_z^2/M_Z^2$  factors, their effect has to be studied if one aims to achieve a theoretical prediction at the level of 1% accuracy. This has been thoroughly done, to lowest order in  $\alpha_{em}$ , in a previous paper,<sup>5</sup> and we shall summarize the technique in the Appendix. The result is

that the remaining photon exchange contributions can be safely neglected to the required 1% accuracy, thus allowing the conclusion of Eq. (2.8) to remain valid within this approximation.

### 3. $A_{LR}$ Off Resonance to Lowest Order in $\alpha_{em}$

We now examine  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  off resonance to lowest order in  $\alpha_{em}$ . It is convenient<sup>4</sup> to write the differential cross section for  $e^+e^- \rightarrow \text{hadrons}$  in terms of the inclusive structure functions  $W_{1,2,3}^{\alpha\beta}$  where  $W_i^{\gamma\gamma}$  comes from the square of the photon exchange,  $W_i^{ZZ}$  from the square of the  $Z^0$  exchange and  $W_i^{\gamma Z}$  from the interference term between the photon exchange and  $Z^0$  exchange. The inclusive structure functions describe the process  $e^+e^- \rightarrow X + \text{anything}$ , where  $X$  with momentum  $\tilde{p}_\mu$  is some experimentally tagged particle which makes an angle  $\xi$  with respect to the electron beam and carries an energy fraction  $x = 2\tilde{p}_0/\sqrt{s}$  (see Fig. 3). The  $W_i^{\alpha\beta}$  are certain functions of  $x$  and  $s$ . If we generalize the helicity coupling constants  $g_{Le}, g_{Re}$  defined in Fig. 1 to include  $g_{Le}^\alpha, g_{Re}^\alpha$  with  $\alpha = \gamma, Z$ , we have for massless electrons.

$$\begin{aligned} \frac{d\sigma_L}{d\Omega} &\sim \sum_{\alpha,\beta} g_{Le}^\alpha g_{Le}^{\beta*} G^\alpha G^{\beta*} \\ &\times \left[ W_1^{\alpha\beta} + \kappa_2 W_2^{\alpha\beta} \sin^2 \xi + \kappa_3 W_3^{\alpha\beta} \cos \xi \right] \end{aligned} \quad (3.1)$$

$$\begin{aligned} \frac{d\sigma_R}{d\Omega} &\sim \sum_{\alpha,\beta} g_{Re}^\alpha g_{Re}^{\beta*} G^\alpha G^{\beta*} \\ &\times \left[ W_1^{\alpha\beta} + \kappa_2 W_2^{\alpha\beta} \sin^2 \xi - \kappa_3 W_3^{\alpha\beta} \cos \xi \right]. \end{aligned} \quad (3.2)$$

Here  $G^\alpha$  are the photon and  $Z^0$  propagators in lowest order in  $\alpha_{em}$ :

$$G^\gamma = \frac{1}{q^2}, \quad G^Z = \frac{1}{q^2 + M_Z^2 - iM_Z\Gamma_Z} \quad (3.3)$$

and  $\kappa_{2,3}$  are kinematical factors which do not depend on  $\xi$ ,  $\kappa_2 = |\tilde{p}^2|/2$ ,  $\kappa_3 = |\tilde{p}|\sqrt{s}$  with  $s = -q^2$  in our metric. If we now integrate symmetrically in  $\cos \xi$  from -1 to +1 the  $W_3$  terms in  $\sigma_{L,R}$  disappear. Then the longitudinal polarization asymmetry is after integrating over  $x$  for a massless final state tagged hadron ( $\tilde{p}_0 = |\tilde{p}|$ ),

$$A_{LR}(s) = \frac{\sum_{\alpha,\beta} (g_{Le}^\alpha g_{Le}^{\beta*} - g_{Re}^\alpha g_{Re}^{\beta*}) G^\alpha G^{\beta*} I^{\alpha\beta}}{\sum_{\alpha,\beta} (g_{Le}^\alpha g_{Le}^{\beta*} + g_{Re}^\alpha g_{Re}^{\beta*}) G^\alpha G^{\beta*} I^{\alpha\beta}} \quad (3.4)$$

where

$$I^{\alpha\beta} = \int_0^1 dx x \left[ W_1^{\alpha\beta} + \frac{sx^2}{12} W_2^{\alpha\beta} \right]. \quad (3.5)$$

Note that since we integrated from -1 to +1 and over all tagged hadron energies  $x$   $I^{\alpha\beta}$  contains of course exactly the combination of structure functions appearing in the *total* cross section.

In perturbative QCD of *massless* quarks the  $\alpha_s$  corrections can then be included as:

$$I^{\alpha\beta}(q^2) = I_{|\alpha_s=0}^{\alpha\beta} \left[ 1 + \frac{\alpha_s(q^2)}{\pi} + O(\alpha_s^2) \right]. \quad (3.6)$$

Thus, the dependence of strong interaction would cancel through order  $\alpha_s$  in  $A_{L,R}^{e^+e^- \rightarrow \text{hadrons}}$  for *light hadrons in total cross sections even off resonance.*<sup>#2</sup>

---

#2 For top quark production, this argument is no longer valid. Also the assumption of masslessness for, say,  $b$  quarks is suspect. A more detailed discussion of the cancellation of  $O(\alpha_s)$  contribution to  $A_{LR}$  is given in the Appendix, along with some warning as to possible difficulties.

Before moving on to the  $O(\alpha_{em})$  corrections we note the following important property of  $A_{LR}$ . Although away from resonance it is final-state flavor dependent (and strong interaction independent), it is a smooth function of  $\sqrt{s}$  which depends very weakly on  $\sqrt{s}$  near the pole. This is illustrated in Fig. 4 where we display  $A_{LR}$ , calculated with the computer program BREMMUS discussed in the next section, for various final states. These properties will be very useful when discussing the effects of initial state bremsstrahlung in the next section.

#### 4. $O(\alpha_{em})$ Corrections to $A_{LR}$

We now turn to the issue of  $O(\alpha_{em})$  corrections to  $A_{LR}$ . These are of several types and we deal with each class separately below. The first class is the so called “oblique” corrections depicted in Fig. 5. The shaded blobs are the renormalized 1PI vector self-energies. As has been shown,<sup>1</sup> these have the effect of renormalizing the coupling constants of photons and  $Z^0$ 's to fermions in  $e^+e^- \rightarrow \bar{f}f$ ,  $(g_{L,R}^\gamma)_e$ ,  $(g_{L,R}^Z)_e$ ,  $(g_{L,R}^\gamma)_f$ ,  $(g_{L,R}^Z)_f$ , making them functions of  $q^2 = -s$ . Imagine first that only  $Z^0$  exchange occurred. Then according to Eq. (2.8) the dependence on  $(g_{L,R}^Z)_f$  would cancel in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  and the dependence on  $(g_{L,R}^Z)_e$  would be exactly the same as in  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}$ . Thus the important information about 1 loop effects in GSW and beyond<sup>1,3</sup> in the  $eZ$  coupling would be preserved in  $A_{LR}^{e^+e^- \rightarrow \bar{f}f}$ . The only problem is that there is also photon exchange, but the effects of the renormalization of  $(g_{L,R}^\gamma)_e$  and  $(g_{L,R}^\gamma)_f$  would be first felt at  $Z^0$  pole at  $O\left(\frac{\alpha}{\pi} \frac{\Gamma_Z^2}{M_Z^2}\right)$  if all such corrections were real and at  $O\left(\frac{\alpha}{\pi} \frac{\Gamma_Z}{M_Z}\right)$  if the oblique corrections had imaginary parts as well. This is, at worst, an effect of  $\sim O(10^{-4})$  and so must be negligible. Thus at  $Z^0$  pole  $A_{LR}^{e^+e^- \rightarrow \bar{f}f} = A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}$  including oblique corrections in both LHS and RHS and hadronization in the RHS as well.

The next set of corrections are the so-called “direct” corrections to the electron vertices depicted in Fig. 6. The shaded blob depicts the 1PI  $O(\alpha_{em})$  corrections to the  $Z$  and  $\gamma$  coupling to electrons. These again have only the effect on renormalizing these couplings making them functions of  $s$ , and so the argument given above holds as does Eq. (2.8). The next set of corrections is depicted in Fig. 7. Again, these only renormalize  $(g_{L,R})_f$  and the usual argument applies on  $Z^0$  pole as does Eq. (2.8). We might worry though about those corrections having to do with hadrons rather than quarks as in Fig. 8. But such graphs would only give  $O(\alpha_{em})$  corrections to the  $Z^0$  total decay rate when the final-state hadrons are integrated over a  $4\pi$  detector, and this cancels in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  as argued in Eq. (2.8). They would reappear in the photon exchange graphs, but as argued above would again only contribute negligibly to  $O\left(\frac{\alpha}{\pi} \frac{\Gamma_Z}{M_Z}\right)$  at worst. The last of the purely weak corrections have the structure of boxes as in Fig. 9. These cannot have a  $Z^0$  pole structure (on  $Z^0$  resonance we do not have enough energy to create two  $Z^0$ 's or two  $W$ 's) at  $q^2 = -M_Z^2$  and so contribute negligibly.

We now turn to QED corrections, the most dangerous of all. The largest such corrections come from the infrared part of the QED vertices and initial state soft photon bremsstrahlung depicted in Fig. 10. The infrared part divergent in the photon mass  $\lambda$  in Fig. 10a (part of the “direct” corrections) is of course cancelled by that in Fig. 10b, leaving us with a large correction depending upon the experimental resolution  $\Delta E$  as  $\lambda \rightarrow 0$ . After exponentiation (inclusion of many soft photons) this has the effect

$$\sigma_{L,R} \rightarrow \sigma_{L,R} \left( \frac{\Delta E}{E} \right)^{\frac{2\alpha}{\pi}} \left( \ln \frac{s}{m_e^2} - 1 \right) \quad (4.1)$$

with  $E$  the beam energy and experimental resolution  $\Delta E \simeq 0.01 E$ . But this

helicity independent factor cancels in  $A_{LR}$ . The remaining contribution of Fig. 10a QED vertices gives an  $s$  dependent renormalization of  $(g_{L,R}^\gamma)_e$  and  $(g_{L,R}^Z)_e$  and the arguments given above still apply.

The remaining contributions from Fig. 10b are divided into two parts. The first set are soft photons or hard (detectable) almost beam collinear photons but in any case with  $k \ll p, p'$ . As is well-known these mostly contribute to the classical radiation field after you add up enough of them (diagrams with more such independent initial state bremsstrahlung photons than in Fig. 10b). Thus we write

$$\sigma_L^{e^+e^- \rightarrow \bar{f}f + \text{photons}}(s) = \sigma_L^{e^+e^- \rightarrow \bar{f}f}(s) + \frac{\alpha}{\pi} \int_0^s ds' P(s') \sigma_L^{e^+e^- \rightarrow \bar{f}f}(s') \quad (4.2)$$

where for one photon bremsstrahlung:

$$P(s') \sim \left( \frac{p}{p \cdot k} - \frac{p'}{p' \cdot k} \right)^2. \quad (4.3)$$

Here  $s' = -(p - p' - k)^2$  and  $\frac{\alpha}{\pi} P(s')$  is the probability of bremsstrahlung such that momentum  $s'$  flows through the virtual  $\gamma$  or  $Z^0$  in Fig. 10b. Similarly we write for  $k \ll p, p'$

$$\sigma_R^{e^+e^- \rightarrow \bar{f}f + \text{photons}}(s) = \sigma_R^{e^+e^- \rightarrow \bar{f}f}(s) + \frac{\alpha}{\pi} \int_0^s ds' P(s') \sigma_R^{e^+e^- \rightarrow \bar{f}f}(s) \quad (4.4)$$

where the *same* helicity independent function  $P(s')$  appears in  $\sigma_R$ . A little

manipulation yields to  $O(\alpha_{em})$ :

$$\begin{aligned}
A_{LR}^{e^+e^- \rightarrow \bar{f}f + \text{photons}}(s) &\simeq A_{LR}(s)^{e^+e^- \rightarrow \bar{f}f} \\
&+ \frac{\alpha}{\pi} \int^s \left[ A_{LR}^{e^+e^- \rightarrow \bar{f}f}(s') - A_{LR}^{e^+e^- \rightarrow \bar{f}f}(s) \right] \\
&\times \frac{\sigma_t^{e^+e^- \rightarrow \bar{f}f}(s')}{\sigma_t^{e^+e^- \rightarrow \bar{f}f}(s)} P(s') ds', \quad \sigma_t = \sigma_L + \sigma_R.
\end{aligned} \tag{4.5}$$

We now note the following facts about the second term on the RHS:  $A_{LR}^{e^+e^- \rightarrow \bar{f}f}(s)$  is not a steep function of  $s$  near  $Z^0$  resonance as indicated in Fig. 4 and so the bracket is very small. Further, at  $s = M_Z^2$ ,  $\sigma_t(s')/\sigma_t(s) \leq 1$  because of the  $Z^0$  peaking structure. Thus initial state soft radiation is negligible for  $A_{LR}$ . Note that  $A_{FB}^{e^+e^- \rightarrow \mu^+\mu^-}$  is a *very* steep function of  $s$  near  $Z^0$  resonance, and so there will be no such cancellation in that case. These comments are borne out by the direct calculations in 1982 of soft photon QED corrections to various  $e^+e^-$  processes with polarized electrons by Bohm and Hollik.<sup>6</sup> We defer discussion of hard photon  $k \simeq p, p'$  effect from Fig. 10b until later.

The next set of graphs to be considered, shown in Fig. 11, integrates symmetrically to zero in  $\cos\theta$  because of the  $G$ -parity conjugation properties of the photon. Now consider the interference terms between initial and final state bremsstrahlung in Fig. 12. These are again divided into two groups. The first group is soft photons or hard collinear with  $k \ll p, p'$ . These can be written as proportional to

$$\sim \left( \frac{p'}{p' \cdot k} - \frac{p}{p \cdot k} \right) \cdot \left( \frac{q_+}{q_+ \cdot k} - \frac{q_-}{q_- \cdot k} \right) \tag{4.6}$$

where  $q_{\mp}$  are the momenta of  $f$  and  $\bar{f}$ . Under  $(\cos\theta \rightarrow -\cos\theta)$ ,  $q_+ \leftrightarrow q_-$  and the soft parts of the graphs in Fig. 12 also integrate symmetrically in  $\cos\theta$  to zero.

One may worry about the exponentiation factor of the infrared part  $\sim \ell n \lambda$  (with  $\lambda$  the photon mass) which comes from many such final state photons' interference with initial state photons. After cancellation of the IR parts with the IR parts of QED box graphs with at least one  $\gamma$  to be discussed later, a large factor

$$\left(\frac{\Delta E}{E}\right)^{-\frac{4\alpha}{\pi} Q_f \ell n \frac{1 - \cos \theta}{1 + \cos \theta}} \quad (4.7)$$

emerges. But this is helicity independent and factorizes out of  $A_{LR}$ . We defer discussion of hard bremsstrahlung photons  $k \simeq p, p'$  in Fig. 12 until later.

We now turn to final state radiation and QED corrections to final state vertices as in Fig. 13. The graphs of Fig. 13a (also included in the “direct” corrections) simply renormalize  $(g_{L,R}^{\gamma,Z})_f$  and so can be neglected according to our previous arguments. The infrared divergent part of course is controlled by the IR divergent part of the graphs of Fig. 13b resulting in a helicity independent factor

$$\left(\frac{\Delta E}{E}\right)^{\frac{2\alpha}{\pi} Q_f^2 \left(\ell n \frac{s}{m_f^2} - 1\right)} \quad (4.8)$$

which is simply absorbed in  $(g_{L,R}^{\gamma,Z})_f$  and thus does not contribute to  $A_{LR}$  on  $Z^0$  resonance. The soft photons or hard collinear photons with  $k \ll p, p'$  in Fig. 13b which result in a factor

$$\left(\frac{q_+}{q_+ \cdot k} - \frac{q_-}{q_- \cdot k}\right)^2 \quad (4.9)$$

do *not* integrate symmetrically to zero, but may be absorbed in the coupling constants  $(g_{L,R}^{\gamma,Z})_f$  when integrated over a  $4\pi$  detector.

It is now time to turn to the  $\gamma - Z$  boxes of Fig. 14. We have already noticed that the IR divergent part as  $\lambda \rightarrow 0$  integrates symmetrically to zero for the one loop graph; even after exponentiation the factor  $\int \frac{\Delta E}{E}$  in Eq. (4.7) can be absorbed into a coupling constant. The contributions in Fig. 14b do not have a double pole on  $Z^0$  resonance, but they do have large logs. The contributions of Fig. 14a have both a double pole and large logs, and are therefore the most dangerous. They have been calculated by Bohm and Hollik<sup>6</sup> as well as by Brown, Decker and Paschos<sup>7</sup> and so, neglecting strong interactions, they are known functions which can be numerically computed. We note that the contributions of Fig. 14, especially 14a, do *not* factorize and therefore, in principle, they bring quark flavor dependence as well as strong interaction dependence to  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  even on  $Z^0$  resonance. We are worried in particular by the hadronization of the final state quarks in Fig. 14a, as depicted in Fig. 15. In fact, the  $|q^2|$  running through the  $Z^0$  line must remain large to get the  $Z^0$  pole enhancement and therefore the  $Z^0$  couples primarily to a free quark line and we probably are able to use perturbative QCD in those parts of the graph. The photon, then, must be soft. Thus, perturbative arguments cannot be used in the evaluation of its coupling to hadrons so that some specific model of hadrons must probably be used; a soft long-wavelength photon will couple to the electric charge of a pion, nucleon or other hadron rather than to the electric charge of their constituent partons. We have evaluated the graph of Fig. 14a numerically for free quarks and found its contribution to  $A_{LR}^{e^+e^- \rightarrow f\bar{f}}$  to be small in agreement with Bohm and Hollik.<sup>6</sup> Certainly, the graphs of Fig. 14a and the strong interaction effects in Fig. 15 deserve further attention.

We continue our discussion of the  $O(\alpha_{em})$  corrections with a comment about

hard photons  $k \simeq p, p'$  in Figs. 13b, 12, 10b. These also do not factorize and may give rise to flavor dependence and strong interaction dependence in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  even on  $Z^0$  resonance. The photon cannot be too energetic, however, for then we would lose the  $Z^0$  pole enhancement. Such effects are also deserving of further study. We will give below the results of the numerical calculation of these non-factorizing graphs in order to estimate the associated strong interaction uncertainties.

So far all of our remarks have been qualitative in nature. We now turn to quantitative results<sup>8</sup> for the longitudinal polarization asymmetry for  $e^+e^- \rightarrow f\bar{f}(\gamma)$  where  $f = u, d, \mu$  and either zero or one photon is included in the final state. These have been computed<sup>9</sup> through  $O(\alpha_{em})$  including *all* effects<sup>‡3</sup> in the GSW  $SU(2)_L \times U(1)$  model, i.e. all “oblique” and “direct” electroweak radiative corrections as well as boxes and QED corrections with vertices and both soft and hard bremsstrahlung of *either zero or one photon*. The first calculation of electroweak GSW radiative corrections to  $A_{LR}^{e^+e^- \rightarrow f\bar{f}}$  was by B. W. Lynn and R. G. Stuart<sup>9</sup>; it was first stated there that the longitudinal polarization asymmetry on  $Z^0$  resonance including Born terms and “oblique” and other  $O(\alpha_{em})$  weak corrections was almost independent of final state flavor and that the leading perturbative QCD corrections cancelled.  $A_{LR}(-M_Z^2)$  was first shown independent of *soft* bremsstrahlung and QED vertices by M. Bohm and W. Hollik.<sup>6</sup> The amplitudes for hard photon bremsstrahlung with polarized beams were first written down by R. Kleiss.<sup>9</sup>

The Monte Carlo generator BREMMUS was written so that the various ex-

---

‡3 Except those proportional to an external fermion mass  $\sim m_e^2/q^2, m_f^2/q^2$  which are negligible for our purposes here but are not so for heavy top quarks in the final state.

perimental cuts could be directly implemented. At the time of this writing, it is the *only* complete  $O(\alpha_{em}^3)$  electroweak Monte Carlo program for  $e^+e^-$  polarized  $\rightarrow f\bar{f}(\gamma)$ . It includes some higher  $O(\alpha_{em}^4)$  effects as well and will be discussed thoroughly elsewhere.<sup>8</sup> BREMMUS allows us to compare directly theoretical and experimental results including the detector dependent experimental cuts. It contains QCD strong interaction effects *only* in vector boson vacuum polarization graphs; no attempt has been made to include by either perturbative QCD or hadronization models the strong interactions of final state quarks.

The numerical results for  $A_{LR}^{e^+e^- \rightarrow f\bar{f}(\gamma)}$  with  $f = u, d, \mu$  are given in Table I. There we have taken  $M_Z = 94$  GeV,  $m_{top} = 30$  GeV,  $m_{Higgs} = 100$  GeV and  $m_e = 0$  (except in infrared logs) and  $m_f = 0.1$  GeV. Dependence on the final state fermion mass (kept in IR logs only) is negligible for  $m_f < 5$  GeV. The results are displayed for three center-of-mass energies:  $M_Z - 1$  GeV,  $M_Z$  and  $M_Z + 1$  GeV. We take  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  as given by  $e^+e^- \rightarrow 2\bar{u}u(\gamma) + 3\bar{d}d(\gamma)$  meant to mimic  $udscb$  quarks.

Events generated were integrated over a  $4\pi$  detector and the beam polarization was taken to be  $P = 100\%$ . 100,000 events were generated in each run. In addition the angle between  $f$  or  $\bar{f}$  and the beam lines was required to be greater than  $20^\circ$  and both  $f$  and  $\bar{f}$  were required to carry  $\geq 15$  GeV energy. The maximum hard photon energy was taken to be  $0.9 E_{\text{beam}}$  while the experimental resolution for the soft photons was taken to be  $\Delta E = 0.01 E_{\text{beam}}$ . Three results are displayed for each energy. If  $\xi_{ACOL}$  is the acolinearity cut angle between  $f$  and  $\bar{f}$  we have displayed the results when

- i*) generated events were cut if  $\xi_{ACOL} > 2^\circ$
- ii*) no acolinearity cut was made

iii) the asymmetry is calculated *dropping only the coupling of final state fermions to photons in relative  $O(\alpha_{em})$  graphs*. In other words, the dangerous contributions depicted in Figs. 11, 12, 13a,b, 14a,b as well as the *photon* exchange (but not the  $Z^0$  exchange) graphs in Figs. 10a and 10b have been set to zero in BREMMUS here. Note that the lowest order photon exchange diagram squared in Fig. 16 is still included in the numerical calculation. No acolinearity cut was made.

We now discuss the results of the numerical calculations. Note from comparison of the results with and without the acolinearity cut (entries i) and ii)) that the effect of hard and soft bremsstrahlung is very small for a given flavor. There are still some flavor dependent effects on pole but these can be traced to the graph with pure photon exchange in Fig. 16 as can be seen from comparison with entry iii) which neglects the coupling of final state fermions to photons in relative  $O(\alpha_{em})$  graphs only. As shown above, however, the flavor dependent effects of the pure photon exchange graph in Fig. 16 can be included by calculation using perturbative QCD and thus the largest fraction of flavor dependent effects give negligible strong-interaction uncertainty.

As mentioned above, the computer program BREMMUS contains no final state strong interaction effects. We will assume, however, that final state strong interaction effects can be no larger than flavor-dependent effects calculated in the absence of final state hadronization. We thus take as an upper bound on strong interaction uncertainties in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  the results given by BREMMUS for the various flavor dependent contributions which cannot be calculated in perturbative QCD. These include  $\gamma - Z$  boxes and hard photon effects (as well as other effects dropped in entry iii) in Table I) as discussed above but not the contribution of

Fig. 16. We estimate the theoretical strong interaction uncertainty

$$\Delta A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2) \lesssim \pm 0.006 \pm 0.003 \quad (4.10)$$

where the first error is inferred from Table I (by the difference between entries ii) and iii) in the column with final state  $2\bar{u}u + 3\bar{d}d$ , meant to give the asymmetry with final state  $udscb$  quarks) and the second is from the strong interaction uncertainty in the vector boson vacuum polarization.<sup>10</sup>‡4

Equation (4.10) is the main result of this section. We believe it gives a conservative estimate of the total theoretical error from strong interaction uncertainties. We conjecture that more sophisticated calculations (higher order in perturbative QCD, specific hadronization models, inclusion of more soft and hard photons in the initial and final state, etc.) can bring the total strong interaction theoretical error down to  $\pm 0.003$ , roughly 1% of  $A_{LR}(-M_Z^2)$ . This must then be the experimental error design goal.

## 5. Measurement of $A_{LR}$ and Conclusions.

Having finished our discussion of the longitudinal polarization asymmetry  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  near  $Z^0$  resonance, we now turn to the experimental implications of this asymmetry for testing GSW at the one loop level as well as the possibility of theories beyond GSW.

Table II contains the shifts  $\delta A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  in the longitudinal polarization asymmetry for various sources of interesting and new physics. These are

---

‡4 Note that (by these rules) even off resonance by  $\pm 1$  GeV, we can ascribe a small strong interaction uncertainty  $\leq \pm 0.013 \pm 0.003$ .

mostly due to “oblique” radiative corrections<sup>1</sup> or to the effect of new gauge particles in extended gauge groups<sup>3</sup> at tree level and so are the same as the shifts in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  as proved in Refs. 1 and 3.

$$\delta A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2) = \delta A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2) \quad (5.1)$$

These then are typically of order 1% although they can be much larger; the goal must then be to measure experimentally and interpret theoretically  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  to *better* than  $\pm 0.01$ . Note that the forward backward asymmetry  $A_{FB}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  is much less sensitive to this interesting physics. We compare the shifts in the asymmetries with the shift in the  $W^\pm$  mass  $\delta M_W$  in Table II.

A detailed study of experimental errors, etc., can be found in the formal proposal for  $e^-$  beam polarization of the SLC polarization group SLCPOL<sup>11</sup> and much of what follows is drawn from there. The main source of systematic experimental error for  $A_{LR}$  is the uncertainty  $\Delta P$  in the value of the absolute  $e^-$  beam polarization  $P$ . These we take to be  $P \simeq 40\%$  and  $\frac{\Delta P}{P} = \pm 0.05$ , values already achieved at SLAC in 1978 for the polarized electron-deuteron experiment. Note however that the longitudinal polarization asymmetry is quite insensitive to this systematic error; an experimental error

$$\Delta A_{LR} \simeq \frac{\Delta P}{P} A_{LR} \simeq 0.27 \frac{\Delta P}{P} \quad (5.2)$$

is induced in  $A_{LR}$  for  $M_Z = 94$  GeV. Further, there is a statistical experimental error which depends on the beam luminosity or the number of  $Z^0$ 's produced in  $e^+e^-$  annihilation. It has been shown<sup>10</sup> that the strong interaction uncertainty in  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}$  is  $\pm 0.003$  and, as stressed first in Ref. 10, is mainly due to

the *quoted* experimental uncertainties in  $e^+e^- \rightarrow \text{hadrons}$  in the region  $1 \text{ GeV} \leq \sqrt{s} \leq 10 \text{ GeV}$ . This could be improved to  $\sim \pm 0.0015$  if the experimental error in this region could be reduced to  $\pm 5\%$  in the value of  $R$ .

In Fig. 17 (r.h.s solid line) the total experimental and theoretical uncertainty in  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  is plotted as a function of the beam luminosity for  $\Delta P/P = \pm 0.05$ ,  $P = 40\%$ . Note that we need approximately  $10^6$   $Z^0$ 's to test  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  to  $\sim \pm 0.01$  because the error is statistics dominated until then. We have indicated in this paper, however, that we are able to reduce the total theoretical strong interaction uncertainty in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2)$  to  $\leq \pm 0.01$ . In Fig. 17 (l.h.s. solid line) the resulting total experimental plus theoretical error in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2)$  is plotted as a function of the beam luminosity. Note that this is not statistics dominated after  $\sim 10^5$   $Z^0$ 's. Further, with only  $\sim 5 \times 10^4$   $Z^0$ 's (early in SLC lifetime) the asymmetry can be measured to  $\pm 0.025$  which could be regarded as a measure of  $\sin^2 \theta_W$  to  $\pm 0.003$  giving already a very serious constraint on the physics of Table II.

It may be possible to improve the  $e^-$  beam polarization to  $P \simeq 100\%$  using stressed uniaxial crystals<sup>11</sup> and separately to improve the polarization measurement to  $\frac{\Delta P}{P} = \pm 0.01$  with a Compton polarimeter.<sup>11</sup> In anticipation of these developments, the experimental and theoretical uncertainties in  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  (r.h.s. dashed line) and  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2)$  (l.h.s. dashed line) are plotted in Fig. 17 as functions of beam luminosity for  $P = 40\%$ ,  $\Delta P/P = \pm 0.01$ . Note the increase in sensitivity. This certainly justifies giving high priority to these polarization improvements.

We now compare the sensitivity to new and interesting physics of the longitudinal polarization asymmetry  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  with the forward backward asym-

metry  $A_{FB}^{e^+e^- \rightarrow \mu^+\mu^-}$  on  $Z^0$  resonance. In Fig. 18 these asymmetries are plotted as functions of  $M_Z$  in three cases:

- i)* without new physics (solid lines)  $m_t = 30, m_{Higgs} = 100$  GeV
- ii)* with a  $\rho$  parameter as would be induced at one loop by a heavy top quark  $m_t \simeq 180$  GeV or a new representation of fermions with large custodial  $SU(2)_L \times SU(2)_R$  symmetry breaking (dot-dashed lines).
- iii)* a shift in the asymmetries as would occur, for  $M_t = 30$  GeV,  $M_H = 100$  GeV (dotted lines), but now with a  $\rho$  parameter  $\rho = 1.01$  from, say, the v.e.v. of a Higg's triplet. These lines are *indicative* of the effects of new physics on the asymmetries and are not to be taken as precise predictions.

The rectangles in Figs. 18a and 18b indicate systematic and statistical experimental plus theoretical errors in the asymmetries with  $10^4, 10^5$  and  $10^6$   $Z^0$ 's with increasingly smaller error bars. The boxes include a  $\pm 50$  MeV error on the direct experimental measurement of  $M_Z$ . Note that although  $A_{FB}$  is insensitive,  $A_{LR}$  can be used with relatively few  $Z^0$ 's to probe the effects of new and interesting physics at one loop in GSW, for new  $SU(2)_L \times U(1)$  matter representations from beyond GSW and for new gauge sectors from beyond GSW.

We now turn to a comparison of the power of various precise measurements to constrain GSW at one loop as well as physics from beyond GSW. Imagine that all such experiments can be interpreted as measurements of  $M_Z$ . We plot in Fig. 19 the resulting experimental and theoretical uncertainties in  $M_Z$  from various experimental programs. To the left are "non-SLC/LEP" experiments including a direct measurement of  $M_Z$  by UA1 and UA2, neutrino-hadron scattering (the dotted part of the line indicates theoretical uncertainties beyond the quoted experimental ones) and neutrino-electron scattering as proposed for the 1990's

by the CHARM II collaboration. In the middle we plot SLC/LEP experiments without beam polarization with  $10^4$ ,  $10^5$  and  $10^6$   $Z^0$ 's including a direct mass measurement and the forward-backward asymmetry  $A_{FB}^{e^+e^- \rightarrow \mu^+\mu^-}$ . On the right are plotted proposed SLC/LEP experiments with 40%  $e^-$  beam polarization for  $10^4$ ,  $10^5$  and  $10^6$   $Z^0$ 's. Note that  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  with only  $\sim 5 \times 10^4$   $Z^0$ 's is already the best test of the theory and is bettered only by  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}$  with about  $10^6$   $Z^0$ 's because of its smaller strong interaction uncertainty.<sup>1,9,10</sup>

In conclusion, we have introduced the  $e^-$  beam longitudinal polarization asymmetry  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$ . We have shown that the vast majority of strong interaction and flavor dependent effects cancel at  $Z^0$  resonance. On and off resonance, most flavor dependent effects can be accurately *calculated* in perturbative QCD and a large class of strong interaction effects cancel to  $O(\alpha_s)$ . There are still, though, some problems with the theoretical interpretation of the asymmetry at the one loop  $O(\alpha_{em})$  level, mainly due to  $Z\gamma$  boxes and hard bremsstrahlung. Although we have shown these effects to be numerically small for free final quarks and have good reason to expect these effects to be numerically small for final state hadrons, they certainly deserve further attention. The strong interaction uncertainty in  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2)$  can be reduced to  $\lesssim \pm 0.01$ . The polarization asymmetry  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$  provides a very good test of GSW at the one loop level as well as a constraint on physics beyond GSW and can be done with only  $\sim 5 \times 10^4$   $Z^0$ 's and so early in the lifetime of SLC or LEP with polarized electron beams.

## ACKNOWLEDGEMENTS

BWL would like to thank the Department of Theoretical Physics of the University of Trieste and ISAS (Trieste) for their warm hospitality during July 1986 and the SLC polarization group<sup>11</sup> for interesting discussions. CV would also like to thank the Theoretical Physics Group at SLAC for warm hospitality provided in October 1986. We are indebted to F. M. Renard and C. Y. Prescott for very illuminating discussions. We thank P. Grosse-Weismann for the use of his Fig. 17 and R. Cahn for the use of his Figs. 18 and 19.

## APPENDIX

Consider the process  $e^+e^- \rightarrow \bar{f}f$ , where  $f$  is a certain quark, to lowest order in electroweak interactions but to all orders in the strong interactions. If  $J_\mu^{\gamma,Z}$  are the hadronic components of the photon and  $Z^0$  currents in the Standard Model and  $|F\rangle$  denotes the final  $|\bar{f}f\rangle$  state, we have

$$\begin{aligned} & \langle 0|J_\mu^i|F\rangle \langle F|J_\nu^j|0\rangle \\ & = S_{\mu\nu}F_S^{ij}(\tilde{p}) + A_{\mu\nu}F_A^{ij}(\tilde{p}) ; \quad i, j = \gamma, Z \end{aligned} \tag{A.1}$$

where  $S_{\mu\nu}$ ,  $A_{\mu\nu}$  are kinematical coefficients which are symmetric and antisymmetric in the Lorentz indices and  $F_{S,A}(\tilde{p})$  contain the full effect of flavor and strong interaction dependence of final states with a tagged hadron of momentum  $\tilde{p}$  plus anything. When integrated symmetrically in  $\cos\theta$ ,  $\int F_A^{ij}$  vanishes and then as discussed in Ref. 5, one is led to an expression for the longitudinal polarization asymmetry for the process  $e^+e^- \rightarrow \bar{f}f$  with hadronization in terms of the symmetric parts  $F_S^{ij}$ . Note that, while  $F_S^{\gamma\gamma}$  and  $F_S^{ZZ}$  are real,  $F_S^{\gamma Z}$  in principle contains an imaginary part which must be taken into account.

Actually,  $F_S^{\gamma Z}$  can only come from the interference of the photon current with the *vector* part of the  $Z_0$  current. For the latter we write, following the decomposition used in Ref. 10

$$J_{\text{vector}}^Z = - \left[ \frac{(1/2 - s_\theta^2)}{s_\theta c_\theta} J^\gamma + \frac{1}{s_\theta c_\theta} \Delta J \right] \tag{A.2}$$

where  $s_\theta = \sin\theta_w$  is the weak mixing angle ( $c_\theta^2 = 1 - s_\theta^2$ ) and

$$\begin{aligned} \Delta J & = J_{\text{vector}}^3 - \frac{1}{2} J^\gamma \\ & = \frac{1}{4} (J^{(\phi)} - 2J^{(\omega)}) + \Delta J^{(\text{heavy quarks})} \end{aligned} \tag{A.3}$$

where  $\Delta J^{(heavy\ quarks)}$  contains the contributions from heavy (i.e.  $c, b, t \dots$ ) quarks. Note that the current for the vector  $\rho$  meson does not appear in Eq. (A.3) while the current,  $J^{(\phi)}$  and  $J^{(\omega)}$  for the vector  $\phi$  and  $\omega$  do.

On  $Z_0$  resonance, the interference between photon and  $Z$  exchange graphs can contribute if  $F_S^{\gamma Z}$  develops an imaginary part. This can only come from *nondiagonal* (mixing) components, i.e. of the kind

$$\text{Im} \langle 0 | J_\mu^m | F \rangle \langle F | J_\nu^n | 0 \rangle \quad (\text{A.4})$$

where  $m, n$  ( $m \neq n$ ) denote specific light ( $\rho, \omega, \phi$ ) and/or heavy ( $c, b, t$ ) components of the electromagnetic current. We can thus consider two different situations.

1.  $f$  is a light ( $u, d, s$ ) quark. Then, the “heavy”  $m, n$  indices are strongly suppressed by Zweig mechanisms. The light indices are suppressed, conversely, by  $\rho - \omega, \omega - \phi \dots$  mixing parameters. Roughly, we can classify the latter as being of either next order in  $\alpha_{em}$  or proportional to light quark mass differences which are absolutely negligible at the  $M_Z$  scale.
2.  $f$  is a heavy ( $c, b, t \dots$ ) quark. Then, every index is suppressed by Zweig mechanisms.

We thus conclude that  $F_S^{\gamma\gamma}, F_S^{ZZ}$  and  $F_S^{\gamma Z}$  are all real to high accuracy. If we now sum over all final states

$$\tilde{F}_S^{ij} = \sum_F \text{Re} \langle 0 | J^i | F \rangle \langle F | J^j | 0 \rangle \quad (\text{A.5})$$

the  $\tilde{F}_S$  are directly related to the total cross sections for  $e^+e^- \rightarrow \text{hadrons}$ . In perturbative QCD we can use factorization theorems for the strong interactions

of massless quarks and thus

$$\tilde{F}_S^{ij} = \tilde{F}_S^{ij} \Big|_{\alpha_s=0} \left[ 1 + \frac{\alpha_s(\tilde{P})}{\pi} + O(\alpha_s^2(\tilde{P})) \right] \quad (A.6)$$

with  $\tilde{F}_S^{ij}|_{\alpha_s=0}$  calculated in electroweak  $SU(2)_L \times U(1)$  with QCD turned off.

Now consider the longitudinal polarization asymmetry  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}$ . Since this is a *ratio* of total cross sections (with left- and right-handed electron beams) it depends on *ratios* of the  $\tilde{F}_S^{ij}$  and in such ratios strong interactions effects *cancel* at least through  $O(\alpha_s)$ . These facts—not necessarily true for the antisymmetric parts or for the imaginary components of the hadronic tensors and, to our knowledge, for  $(\bar{t}t)$  final states whose quark mass is comparable to  $M_Z$ —allows us to write near the  $Z^0$  resonance ( $f \neq e, \nu_e, t$ ):

$$A_{LR}^{e^+e^- \rightarrow f\bar{f}}(q^2) = A_{LR}^{e^+e^- \rightarrow f\bar{f}}(q^2) \Big|_{\alpha_s=0} + O(\alpha_s^2). \quad (A.7)$$

11. Interference of  $\gamma - \gamma$  boxes with tree level photon exchange.
12. Interference of initial and final state bremsstrahlung.
13. (a)(b) Final state radiation and QED corrections to final state vertices.
14. (a)(b)  $\gamma - Z$  boxes.
15. An example of corrections coming from hadronization of the final state quarks which may give a non-negligible strong interaction uncertainty.
16. Squared photon exchange graph still included in  $A_{LR}$  in entry iii) in Table I. This gives the vast majority of flavor dependent effects.

17. Total experimental and theoretical uncertainty in  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  (r.h.s. lines) and  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2)$  (l.h.s. lines) as a function of the beam luminosity assuming  $\Delta P/P = \pm 0.05$ ,  $P = 40\%$  (solid lines) and  $\Delta P/P = \pm 0.01$ ,  $P = 40\%$  (dashed lines). A theoretical strong interaction uncertainty of  $\pm 0.01$  for  $A_{LR}^{e^+e^- \rightarrow \text{hadrons}}(-M_Z^2)$  has been assumed. It has been shown<sup>10</sup> that the strong interaction uncertainty in  $A_{LR}^{e^+e^- \rightarrow \mu^+\mu^-}(-M_Z^2)$  is  $\pm 0.003$ . Also indicated is the result and total experimental plus theoretical uncertainty in  $\sin^2 \theta_W$ .
18. (a) The left-right asymmetry evaluated at the  $Z$  as a function of the  $Z$  mass. The solid curve corresponds to  $m_t = 30$  GeV,  $M_H = 100$  GeV. The dot-dashed curve corresponds to  $m_t = 180$  GeV,  $M_H = 100$  GeV. The dashed curve corresponds to  $m_t = 30$  GeV and  $M_H = 100$  GeV, but with  $\rho = 1.01$  instead of  $\rho = 1.00$ . The rectangles indicate the expected limits for  $\pm 1\sigma$  about a hypothetical data point on the solid curve with  $M_Z = 93$  GeV with  $P = 40\%$ . The largest rectangle represents the expectation for  $N = 10^4$  observed  $Z$ 's and  $\Delta P/P = 5\%$ . The two smaller ones represent  $N = 10^5$  with  $\Delta P/P = 3\%$  and  $N = 10^6$  with  $\Delta P/P = 1\%$ .
- (b) The forward-backward asymmetry for the  $\mu^+\mu^-$  final state. The conventions are identical those in (a).
19. Comparison of indirect measurements of the  $Z$ -mass, assuming the standard electroweak model, with direct measurements. Squares indicate direct measurements, circles indirect measurements. The open circles and squares indicate future measurements, error bars show  $\pm 1\sigma$ . Existing data are taken from the 1986 Review of Particle Properties. The asymmetry measurements at the SLC show three circumstances:  $N = 10^4$ ,  $\Delta P/P = 5\%$ ;  $N = 10^5$ ,

$\Delta P/P = 3\%$ ;  $N = 10^6$ ,  $\Delta P/P = 1\%$  all with  $P = 40\%$ .

## TABLE CAPTIONS

1. Numerical results for  $A_{LR}^{e^+e^- \rightarrow f\bar{f}(\gamma)}$  with polarization  $P = 100\%$  with up to one photon in the final state calculated to  $O(\alpha_{em})$  in GSW including *all* one loop electroweak effects. Entries are i) events with  $\xi_{ACOL} > 2^\circ$  cut, ii) no acolinearity cut and iii) excluding the contributions of Figs. 11, 12, 13, 14 and the photon exchange (but not the  $Z^0$  exchange) in Figs. 10. Figure 16 is still included and no acolinearity cut has been made in iii). Final state strong interaction effects are neglected. Here  $M_Z = 94$  GeV,  $m_t = 30$  GeV and  $M_H = 100$  GeV.
2. Response of one loop various asymmetries on  $Z_0$  resonance to new one loop physics (taken from Refs. 1 and 3). Results listed are only representative of these *model dependent* effects.

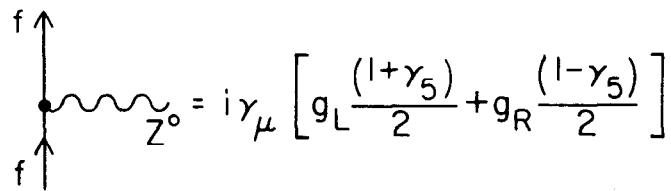

Table I

$$A_{LR}^{e^+e^- \rightarrow f\bar{f}(\gamma)}$$

	$\sqrt{s}$	$\bar{u}u$	$\bar{d}d$	$2\bar{u}u + 3\bar{d}d$	$\mu^+\mu^-$

The diagram shows a vertical line with a dot at its base. Two upward-pointing arrows labeled 'f' are positioned on either side of the dot. A wavy line extends to the right from the dot, labeled with  $Z^{\circ}$ . To the right of the wavy line is an equals sign followed by the mathematical expression  $i\gamma_{\mu} \left[ g_L \frac{(1+\gamma_5)}{2} + g_R \frac{(1-\gamma_5)}{2} \right]$ .
