#### Abstract

We present a new method for determining the electron left-right asymmetry factor, $A_{e}$, by measuring the forward-backward charge flow in samples of hadronic $Z$ events, produced in $e^{+} e^{-}$collisions, with left-handed and righthanded electron-beam polarizations. The raw, left-right charge asymmetry, $Q_{L R}^{\text {raw }}$, is defined. After correction by the measured beam polarization, it provides $A_{e}$ with greatly reduced dependence on Monte Carlo corrections for acceptances and jet charge measurement. The $Q_{L R}^{\text {raw }}$ is also combined with the raw, left-right cross section asymmetry, $A_{L R}^{\text {raw }}$, to obtain $A_{e}$ without the use of the measured electron-beam polarization, and with half the statistical error as that obtained for $A_{e}$ using the polarization corrected $Q_{L R}^{\text {raw }}$ alone. This method gives $\sin ^{2} \theta_{W}^{\mathrm{eff}}=0.2291 \pm 0.0039$ (stat.) $\pm 0.0012$ (syst.). The measurement was performed at a center-of-mass energy of 91.26 GeV with the SLD detector at the SLAC Linear Collider (SLC).

## 1. Introduction

SLD has measured the left-right cross section asymmetry, $A_{L R}=\left(\sigma_{L}-\sigma_{R}\right) /\left(\sigma_{L}+\right.$ $\left.\sigma_{R}\right)$, in the production of $Z$ bosons by $e^{+} e^{-}$collisions. ${ }^{1,2}$ In the Standard Model of the electroweak interactions, this gives the electron left-right asymmetry, $A_{e}=2 v_{e} a_{e} /\left(v_{e}^{2}+\right.$ $a_{e}^{2}$ ), from:

$$
\begin{equation*}
A_{L R}^{\text {raw }}=\left|\mathcal{P}_{e}\right| A_{L R}=\left|\mathcal{P}_{e}\right| A_{e} \tag{1}
\end{equation*}
$$

where $\mathcal{P}_{e}$ is the electron-beam polarization. Since only the total cross sections were observed in this measurement, the forward-backward asymmetries can also be used to

[^0]provide independent information on the couplings to the $Z$. At Born level, the forwardbackward fermion asymmetry at the $Z$ pole (excluding $e^{+} e^{-}$final states) is given by:
\[

$$
\begin{equation*}
A_{F B, f}\left(\mathcal{P}_{e}\right)=-g(a) \frac{\mathcal{P}_{e}-A_{e}}{1-\mathcal{P}_{e} A_{e}} A_{f} \tag{2}
\end{equation*}
$$

\]

where $g(a)=a /\left(1+\frac{1}{3} a^{2}\right), 0<a \leq 1, a=|\cos \theta|_{\max }, \cos \theta$ describes the angle between the outgoing fermion $f$ and the direction of the incident electron, and $A_{f}=2 v_{f} a_{f} /\left(v_{f}^{2}+a_{f}^{2}\right)$. Assuming equal polarization magnitudes and luminosities, we can define $A_{F B, L, f} \equiv$ $A_{F B, f}\left(-\left|\mathcal{P}_{e}\right|\right)$ and $A_{F B, R, f} \equiv A_{F B, f}\left(\left|\mathcal{P}_{e}\right|\right)$ as the forward-backward asymmetries for events produced with left and right beam polarizations.

For a flavor-inclusive sample of $Z$ hadronic final states, we must relate the fermion asymmetries above to charge asymmetries. ${ }^{3-5}$ At parton level the fermion asymmetries would give nonzero, average forward and backward charges for a $q_{f} \bar{q}_{f}$ final state:

$$
\begin{array}{rlrl}
<Q_{F, L, f}^{r a w}> & =q_{f} A_{F B, L, f} & <Q_{F, R, f}^{r a w}>=q_{f} A_{F B, R, f} \\
<Q_{B, L, f}^{r a w}> & =-q_{f} A_{F B, L, f} & & <Q_{F, R, f}^{r a w}>=-q_{f} A_{F B, R, f} \tag{3}
\end{array}
$$

where we can separate "left" and "right" events for SLD. The charge magnitudes can then be averaged into the left and right, forward-backward charge flows:

$$
\begin{align*}
& <Q_{F B, L, f}^{r a w}>=<Q_{F, L, f}^{r a w}>-<Q_{B, L, f}^{r a w}>=2 q_{f} A_{F B, L, f} \\
& <Q_{F B, R, f}^{r a w}>=<Q_{F, R, f}^{r a w}>-<Q_{B, R, f}^{r a w}>=2 q_{f} A_{F B, R, f} . \tag{4}
\end{align*}
$$

Finally, the flavor-inclusive expressions for the polarized $\left(<\tilde{Q}_{F B}^{r a w}>\right)$ and unpolarized $\left.\left(<Q_{F B}\right\rangle\right)$ forward-backward charge flows can be defined by summing over the flavors, weighting by production, and including modifications $\left(d_{f} \epsilon[0,1]\right)$ to account for a reduction in the measured charge magnitudes due to QCD corrections, hadronization effects (including $B^{0} \bar{B}^{0}$ mixing), and decays: ${ }^{6}$

$$
\begin{align*}
<\tilde{Q}_{F B}^{r a w}> & =<Q_{F B, L}^{r a w}>f_{L}-<Q_{F B, R}^{r a w}>f_{R} \\
& =2 g(a)\left|\mathcal{P}_{e}\right| \sum_{f} d_{f} q_{f} R_{f} A_{f}  \tag{5}\\
<Q_{F B}> & =<Q_{F B, L}^{r a w}>f_{L}+<Q_{F B, R}^{r a w}>f_{R} \\
& =2 g(a) A_{e} \sum_{f} d_{f} q_{f} R_{f} A_{f} \tag{6}
\end{align*}
$$

where $f_{L}=\frac{1}{2}\left(1+\left|\mathcal{P}_{e}\right| A_{e}\right)$ and $f_{R}=\frac{1}{2}\left(1-\left|\mathcal{P}_{e}\right| A_{e}\right)$ are the fractions of left and right events, $R_{f}=\Gamma_{f} / \Gamma_{h a d}, \Gamma_{f} \propto v_{f}^{2}+a_{f}^{2}$, and $\Gamma_{h a d}=\sum_{f} \Gamma_{f}$. The quantities $<Q_{F B, L}^{r a w}>$ and $\left\langle Q_{F B, R}^{r a w}\right\rangle$ are now the mean, flavor-inclusive, forward-backward charge flows in left and right events. Since $\left|\mathcal{P}_{e}\right|$ and $A_{e}$ factor out of the sums, the ratio of these charge asymmetries (assuming the sum is not identically zero) has the simple form:

$$
Q_{L R}^{r a w} \equiv \frac{<\tilde{Q}_{F B}^{r a w}>}{<Q_{F B}>}
$$

$$
\begin{align*}
& =\frac{\left\langle Q_{F B, L}^{r a w}>f_{L}-<Q_{F B, R}^{r a w}>f_{R}\right.}{\left\langle Q_{F B, L}^{r a w}>f_{L}+<Q_{F B, R}^{r a w}>f_{R}\right.} \\
& =\frac{\left|\mathcal{P}_{e}\right|}{A_{e}} \tag{7}
\end{align*}
$$

Thus, by measuring the left-right charge asymmetry, $Q_{L R}=Q_{L R}^{\text {raw }} /\left|\mathcal{P}_{e}\right|, A_{e}$ can be obtained in a manner largely independent from the $A_{L R}^{\text {raw }}$ measurement. ${ }^{7}$ At lowest order, the expression for $Q_{L R}^{r a w}$ shows that uncertainties in the acceptance and jet charge measurement are cancelled out, thus reducing the dependence on the Monte Carlo methods for such corrections, and subsequent systematic errors. Many of the remaining errors due to instrumental effects are also reduced in the $<\tilde{Q}_{F B}>$ measurement, but not in the $<Q_{F B}>$, and must be considered for corrections and systematic errors to $Q_{L R}^{\text {raw }}$. Comparing $A_{e}$ obtained from $Q_{L R}^{\text {raw }}$ to that obtained from $A_{L R}^{\text {raw }}$ provides an inclusive test of our understanding of the charged final states of $Z$ decays. Furthermore, since $Q_{L R}^{r a w}$ is formed from the ratio of $\left|\mathcal{P}_{e}\right|$ and $A_{e}$ whereas $A_{L R}^{\text {raw }}$ is formed from their product, the two measurements may be combined to measure $A_{e}$ without the use of a direct measurement of the polarization:

$$
\begin{equation*}
A_{e}=\sqrt{\frac{A_{L R}^{r a w}}{Q_{L R}^{r a w}}} . \tag{8}
\end{equation*}
$$

This method takes advantage of both measurements of $A_{e}$ and eliminates the systematic error due to the polarization measurement. Alternatively, $Q_{L R}^{r a w}$ and $A_{L R}^{r a w}$ may be combined to obtain a check on the measured polarization value:

$$
\begin{equation*}
\left|\mathcal{P}_{e}\right|=\sqrt{A_{L R}^{r a w} Q_{L R}^{\text {raw }}} \tag{9}
\end{equation*}
$$

## 2. Method of Analysis

Details of the SLAC Linear Collider (SLC), the polarized electron source, the measurement of the polarization with the Compton polarimeter, and the SLD experiment are described in Refs. 1 and 2. The results presented here are based on an integrated luminosity of $1.78 \mathrm{pb}^{-1}$ at $\sqrt{s}=91.260 \mathrm{GeV}$, which SLD obtained during the 1993 run with $\left|\mathcal{P}_{e}\right| \approx 63 \%$ at the interation point. Hadronic events are selected using track and event selection cuts that were used in a previous measurement of $\alpha_{s}$ by SLD, ${ }^{8}$ with the following additions. Each event is divided by a plane perpendicular to the thrust axis that is determined using all accepted charged tracks in the event. It is required that $\left|\cos \theta_{T}\right|<0.7, N_{c h} /$ hemis $\geq 3, E_{c h} /$ hemis $>0.1 E_{\text {beam }}$, and total $E_{c h}>0.2 E_{C M}$. Events are rejected if any track has $p_{t o t}>55 \mathrm{GeV} /$ c. A total of 14,723 left events and 12,000 right events are obtained. The measured $\left|\mathcal{P}_{e}\right|$ for this sample is $63.5 \%$ with a $1.7 \%$ systematic error and negligible statistical error as described in Ref. 2.

The forward-backward charge asymmetries are determined as follows. A unit vector along the thrust axis, $\hat{\mathbf{T}}$, is chosen such that $\hat{\mathbf{T}} \cdot \mathbf{p}_{e^{-}}>0$. Tracks are then defined as forward if $\mathbf{p} \cdot \hat{\mathbf{T}}>0$, and backward otherwise. The weighted charge in the forward hemisphere is then calculated for each event from:

$$
\begin{equation*}
Q_{F}=\frac{\sum_{\mathbf{p}_{i} \cdot \hat{\mathbf{T}}>0}\left|\mathbf{p}_{i} \cdot \hat{\mathbf{T}}\right|^{\kappa} q_{i}}{\sum_{\mathbf{p}_{i} \cdot \hat{\mathbf{T}}>0}\left|\mathbf{p}_{i} \cdot \hat{\mathbf{T}}\right|^{\kappa}} \tag{10}
\end{equation*}
$$

Fig. 1. Distributions of the polarized (a) and unpolarized (b), forward-backward charge flows.
where $q_{i}$ is the charge of particle $i$, and $\kappa$ is a weighting factor. The results presented here take $\kappa=1$. The charge in the backward hemisphere, $Q_{B}$, is determined in a similar manner for tracks with $\mathbf{p} \cdot \hat{\mathbf{T}}<0$. The quantity $Q_{F B}=Q_{F}-Q_{B}$ is then found for each event, and averaged for all left events as $\left\langle Q_{F B, L}^{r a w}\right\rangle$, and all right events as $\left\langle Q_{F B, R}^{\text {raw }}\right\rangle$. Finally, $\left\langle\tilde{Q}_{F B}^{\text {raw }}\right\rangle,\left\langle Q_{F B}\right\rangle$, and $Q_{L R}^{\text {raw }}$ are obtained from Eqs. 5, 6, and 7, respectively.

## 3. Preliminary Results

Distributions for $\tilde{Q}_{F B}^{r a w}$ and $Q_{F B}$ are shown in Fig. 1. Having applied a $-17.5 \pm$ $7.3 \%$ correction for a charge-dependent, forward-backward bias to the track sagittas, we obtain the following: $\left\langle Q_{F B, L}^{r a w}\right\rangle=-0.0467 \pm 0.0052,\left\langle Q_{F B, R}^{r a w}\right\rangle=0.0330 \pm 0.0058$, $\left.<\tilde{Q}_{F B}^{r a w}\right\rangle=-0.0405 \pm 0.0039,\left\langle Q_{F B}>=-0.0109 \pm 0.0039,\left(Q_{L R}^{r a w}\right)^{-1}=0.269 \pm\right.$ 0.096 , and $A_{L R}^{r a w}=0.1019 \pm 0.0061 .{ }^{9}$

We have investigated a number of possible systematic errors due to biases of the instrumentation, analysis, and various backgrounds. The relative uncertainties in $Q_{L R}$ due to these errors are summarized in Table 1.

## 4. Summary

The value for the left-right charge asymmetry, before radiative corrections, but corrected for the measured polarization and including the systematic error, is:

$$
\begin{equation*}
Q_{L R}^{-1}=0.171 \pm 0.061(\text { stat. }) \pm 0.019(\text { syst. }) \tag{11}
\end{equation*}
$$

| Source of uncertainty | $\delta Q_{L R} / Q_{L R}(\%)$ |
| :--- | ---: |
| polarization measurement and chromaticity correction | 1.7 |
| q dependent, F-B sagitta bias, $(6.0 \pm 3.3) 10^{-4} \mathrm{GeV}^{-1}$ | 8.9 |
| q independent, F-B sagitta bias, $(8.0 \pm 3.2) 10^{-4} \mathrm{GeV}^{-1}$ | 0.3 |
| F-B asymmetry of SLD central material, $(0.22 \pm 0.81) \%$ | 0.5 |
| q independent, F-B track losses from recon. and accept. biases | 0.1 |
| unphysical $p_{\text {tot }}$ tracks | 0.8 |
| dependence of $Q_{L R}^{\text {raw }}$ on the value of $\kappa$ | 5.0 |
| polarization effects in hadronization and decays | 0.5 |
| SLC track backgrounds, $<Q_{F B}>S L C=(-1.3 \pm 2.0) 10^{-4}$ | 0.0 |
| $e^{+} e^{-}$final state backgrounds, $(1.2 \pm 0.9) 10^{-5}$ | 0.7 |
| two photon backgrounds, $<1 . \times 10^{-4} @ 95 \% C . L$. | 1.0 |
| charge dilution factors in calculations of radiative corrections | 4.0 |
| Total | 11.2 |

Table 1. Summary of Systematic Errors
Radiative corrections are made to the measured asymmetries using the ZFITTER program. ${ }^{10}$ After these corrections, the following values are obtained:

$$
\begin{align*}
A_{e} & =0.169 \pm 0.061(\text { stat. }) \pm 0.019(\text { syst. })  \tag{12}\\
\sin ^{2} \theta_{W}^{\text {eff }} & =0.2288 \pm 0.0080(\text { stat. }) \pm 0.0024(\text { syst. }) \tag{13}
\end{align*}
$$

These results were obtained using $M_{Z}=91.187 \mathrm{GeV} / \mathrm{c}^{2}, \alpha_{s}=0.123$, Higgs mass $M_{H}=300 \mathrm{GeV} / \mathrm{c}^{2}$, and top mass $m_{t}=250_{-240}^{+120}$ (stat.) ${ }_{-50}^{+40}$ (syst.) $\pm 20\left(\delta M_{H}\right) \mathrm{GeV} / \mathrm{c}^{2}$, where the last error on $m_{t}$ is due to a variation of $M_{H} \epsilon\left[70,10^{3} \mathrm{GeV} / \mathrm{c}^{2}\right]$. These results are largely independent of those previously obtained by SLD from $A_{L R}$.

We can also obtain $A_{e}$ from $Q_{L R}^{\text {raw }}$ and $A_{L R}^{\text {raw }}$ using Eq. 8, without the use of the measured polarization. After radiative corrections to the raw results, we obtain:

$$
\begin{align*}
A_{e} & =0.1659 \pm 0.0302 \text { (stat.) } \pm 0.0092 \text { (syst.) }  \tag{14}\\
\sin ^{2} \theta_{W}^{\text {eff }} & =0.2291 \pm 0.0039 \text { (stat.) } \pm 0.0012 \text { (syst.) } \tag{15}
\end{align*}
$$

with $m_{t}=250_{-100}^{+70}$ (stat.) $\pm 20$ (syst. $) \pm 20\left(\delta M_{H}\right) \mathrm{GeV} / \mathrm{c}^{2}$. These results are alternative, not independent, of those obtained from $A_{L R}^{r a w}$, and $Q_{L R}^{r a w}$, and using the measured polarization. From Eq. 9, they are also equivalent to $\left|\mathcal{P}_{e}\right|=0.616_{-0.087}^{+0.153}$ (stat.) ${ }_{-0.031}^{+0.037}$ (syst.), which agrees well with the measured $\left|\mathcal{P}_{e}\right|$ of the selected data sample.
