Kyiv, Ukraine *23–29 June 2003*

Part 1

Kyiv • 2004

УДК 517.95:517.958:512.81(06)

Симетрія у нелінійній математичній фізиці // Праці Інституту математики НАН України. — Т. 50. — Ч. 1. — Київ: Інститут математики НАН України, 2004 / Ред.: А.Г. Нікітін, В.М. Бойко, Р.О. Попович, І.А. Єгорченко. — 524 с.

Цей том "Праць Інституту математики НАН України" є збірником статей учасників П'ятої міжнародної конференції "Симетрія у нелінійній математичній фізиці". Збірник складається з трьох частин, кожна з яких видана окремою книгою.

Дане видання є першою частиною і включає праці, присвячені застосуванню теоретико-групових методів у математичній фізиці та теорії диференціальних рівнянь, а також питанням інтегровності.

Розраховано на наукових працівників, аспірантів, які цікавляться новими тенденціями симетрійного аналізу та його застосувань.

Symmetry in Nonlinear Mathematical Physics // Proceedings of Institute of Mathematics of NAS of Ukraine. — V. 50. — Part 1. — Kyiv: Institute of Mathematics of NAS of Ukraine, 2004 / Editors: A.G. Nikitin, V.M. Boyko, R.O. Popovych, I.A. Yehorchenko. — 524 p.

This volume of the Proceedings of Institute of Mathematics of NAS of Ukraine includes papers of participants of the Fifth International Conference "Symmetry in Nonlinear Mathematical Physics". The collection consists of three parts which are published as separate issues.

This issue is the first part which contains papers devoted to applications of group-theoretical methods in mathematical physics and differential equations, and to the integrability problems.

The book may be useful for researchers and post graduate students who are interested in modern trends in symmetry analysis and its applications.

Preface

Specialisation of science long ago resulted in that researchers in different fields practically lost ability to understand each other. Even mathematics that permeates absolutely all serious theoretical studies tends to increasing divergence of its various branches, including those that quite recently were the single whole.

On the other side there is increased universal penetration of methods and ideas generated in different fields. One of such concepts applicable in a vast multitude of areas of modern science is symmetry. And symmetry is the main link for the papers included into the present Proceedings.

Symmetry is a multi-faceted concept. It was discovered in ancient times and is utilised extensively in arts, natural sciences, mathematics, industry, crafts and design etc. Even in mathematics, in fact we have a large variety of different kinds of symmetries. And our conference that gathered many experts from rather different fields may serve as a proof to this fact.

The Fifth International Conference "Symmetry in Nonlinear Mathematical Physics" was traditionally organised by the Institute of Mathematics of the National Academy of Sciences of Ukraine. It continues the series of meetings started in 1995 by Professor Wilhelm Fushchych. We are very pleased to see that popularity of these meetings increases with each new conference.

The Fifth Conference was the most representative with more than 250 participants from 38 countries presented their talks, the majority of which were included into these Proceedings. The titles of the conference talks not presented for publication are given at the end of Part 3.

The Proceedings are published in three parts and include 209 papers. A significant proportion of the papers deal with integrability as well as mainstream subjects in the Lie theory application in mathematical physics that is analysis of symmetries of differential equations, construction of invariants, symmetry reductions and construction of exact solutions. These papers are collected mostly in Part 1. The papers on supersymmetry and application of symmetry in physics are presented in Part 2. Papers on algebra, group and representation theory, together with various symmetry-related problems were included into Part 3.

We believe that these Proceedings will be a worthy summary of the successful conference, and contain valuable input into development of ideas and methods related to studies and applications of symmetries. We would wish them to serve as an inspiration for future research for all readers.

Anatoly NIKITIN

March, 2004

Fifth International Conference

SYMMETRY IN NONLINEAR MATHEMATICAL PHYSICS

June 23–29, 2003, Kyiv, Ukraine

Organized by

Institute of Mathematics of the National Academy of Sciences of Ukraine

Organizing Committee

A. Nikitin, *Co-Chairman* (Institute of Mathematics, Kyiv, Ukraine)
A. Samoilenko, *Co-Chairman* (Institute of Mathematics, Kyiv, Ukraine)
J. Beckers (University of Liége, Belgium)
G. Bluman (UBC, Vancouver, Canada)
J. Cariñena (Universidad de Zaragoza, Spain)
J. Cervero (Universidad de Salamanca, Spain)
P. Clarkson (University of Kent at Canterbury, UK)
E. Corrigan (University of York, UK)
N. Debergh (University of Liége, Belgium)
H.-D. Doebner (Technical University of Clausthal, Germany)
G. Gaeta (Universita di Milano, Italy)
G. Goldin (Rutgers University, New Jersey, USA)
B.K. Harrison (Britham Young University, Utah, USA)
N. Ibragimov (Blekinge Institute of Technology, Sweden)
V. Kadyshevsky (Joint Institute for Nuclear Research, Dubna, Russia)
A. Klimyk (Bogolyubov Institute for Theoretical Physics, Kyiv, Ukraine)
J. Krasil'shchik (Independent University of Moscow, Moscow, Russia)
M. Lakshmanan (Bharathidasan University, Tiruchirappalli, India)
P. Leach (University of Natal, Durban, South Africa)
W. Miller (University of Minnesota, Minneapolis, USA)
M. Moshinsky (Universidad Nacional Autonoma de Mexico, Instituto de Fisica, Mexico)
J. Niederle (Institute of Physics, Prague, Czech Republic)
P. Olver (University of Minnesota, Minneapolis, USA)
G. Pogosyan (UNAM, Cuernavaca, Mexico & JINR, Dubna, Russia)
I. Skrypnyk (Institute of Mathematics, Kyiv, Ukraine)
M. Tajiri (Osaka Prefecture University, Japan)
P. Winternitz (Universite de Montreal, Canada)
I. Yehorchenko (Institute of Mathematics, Kyiv, Ukraine)
R. Zhdanov (Institute of Mathematics, Kyiv, Ukraine)

Local Organizing Committee

A. Nikitin, T. Barannyk, V. Bondarchuk, V. Boyko, A. Galkin, N. Ivanova, M. Lutfullin, O. Magda, V. Nenya, M. Nesterenko, H. Popovych, R. Popovych, V. Popovych, A. Sergyeyev, S. Spichak, V. Stogniy, V. Tretynyk, L. Velychko, A. Vorobyova, I. Yehorchenko, O. Zhalij, D. Zhavrots'kyi, O. Zhukovsky

Fifth International Conference

SYMMETRY IN NONLINEAR MATHEMATICAL PHYSICS

June 23–29, 2003, Kyiv, Ukraine

TOPICS

* Symmetries of differential equations
* Integrable and superintegrable systems
* Symbolic computations in symmetry analysis
* Dynamical systems, solitons
* Supersymmetry and its generalizations
* Quantum field theory
* Lie groups and algebras, representation theory and special functions
* q-algebras, quantum groups and noncommutative geometry
* Gravitation, cosmology, quantum gravity
* Condensed matter and statistical physics
* Nonlinear phenomena and quantum chaos

Conference Address

Institute of Mathematics
National Academy of Sciences of Ukraine
3 Tereshchenkivska Street
01601 Kyiv 4, Ukraine

Web-page: www.imath.kiev.ua/˜appmath/conf.html

E-mail: appmath@imath.kiev.ua

Fax: +38 044 235 20 10

Phone: +38 044 234 63 22

We invite everybody to participate in the next Conference planned for June 20–26, 2005.

Fifth International Conference

SYMMETRY IN NONLINEAR MATHEMATICAL PHYSICS

June 23–29, 2003, Kyiv, Ukraine

The publication of conference proceedings was partially supported by

- International Association of Mathematical Physics
  http://www.iamp.org/
- Science & Technology Center in Ukraine
  http://www.stcu.int/

We would like to thank for books and journals, which was presented in Conference Exhibition

- American Institute of Physics
  http://www.aip.org/
- Cambridge University Press
  http://uk.cambridge.org/
- Elsevier Science
  http://www.elsevier.com/
- Institute of Physics
  http://www.iop.org/
- Taylor & Francis Group
  http://www.tandf.co.uk/
- World Scientific
  http://www.wspc.com/
- Communication on Pure and Applied Analysis

and for those donated to the library of the Institute of Mathematics.

We would like to thank for technical support during the conference:

- National Technical University of Ukraine “Kyiv Polytechnic Institute”, Kyiv, Ukraine
- International Science and Technology University, Kyiv, Ukraine
- Information and Technology Centre of the National Academy of Sciences of Ukraine

List of Participants

1. **Dmitry L. ABRAROV** (Computing Center of Academy of Science, Moscow, RUSSIA)
   e-mail: abrarov@ccas.ru
2. **Faridon AMDJADI** (Glasgow Caledonian University, Glasgow, UK)
   e-mail: F.Amdjadi@gcal.ac.uk
3. **Andrij ANDREYTSEV** (Kherson State Technical University, Kherson, UKRAINE)
   e-mail: appmath@imath.kiev.ua
4. **Alexander Val. ANTONIOUK** (Institute of Mathematics of NAS of Ukraine,
   Kyiv, UKRAINE) e-mail: antoniouk@imath.kiev.ua
5. **Alexandra Vict. ANTONIOUK** (Institute of Mathematics of NAS of Ukraine,
   Kyiv, UKRAINE) e-mail: antoniouk@imath.kiev.ua
6. **Asao ARAI** (Hokkaido University, Sapporo, JAPAN)
   e-mail: arai@math.sci.hokudai.ac.jp
7. **Leon ARRIOLA** (University of Wisconsin, Whitewater, USA)
   e-mail: arriolal@uww.edu, arriola@t7.lanl.gov
8. **Senol ATAOGLU** (Istanbul Technical University, Istanbul, TURKEY)
   e-mail: ataoglu@itu.edu.tr
9. **Lucas BADOWSKI** (Institute of Physics, A. Mickiewicz University, Poznan, POLAND)
   e-mail: punio@webska.pl
10. **Dumitru BALEANU** (Cankaya University, Ankara, TURKEY)
    e-mail: dumitru@cankaya.edu.tr
11. **Tetyana BARANNYK** (Poltava State Pedagogical University, Poltava, UKRAINE)
    e-mail: slpoltva@e-mail.pl.ua
12. **Peter BASARAB-HORWATH** (Linköping University, SWEDEN)
    e-mail: pehor@mai.liu.se
13. **Orest BATSULA** (Bogolyubov Institute for Theoretical Physics, Kyiv, UKRAINE)
    e-mail: mmtpitp@gluk.org
14. **Yuri BAZILEVICH** (Institute of Continuing Special Education, Pridniprovsk State University
    of Civil Engineering, Dnipropetrovsk, UKRAINE) e-mail: bazilevich@ua.fm
15. **Jules BECKERS** (University of Liege, BELGIUM)
    e-mail: Jules.Beckers@ulg.ac.be
16. **Eugene BELOKOLOS** (Institute of Magnetism of NAS of Ukraine, Kyiv, UKRAINE)
    e-mail: bel@imag.kiev.ua
17. **Carl M. BENDER** (Washington University, St Louis, MO, USA)
    e-mail: cmb@wustl.edu
18. **Donald L. BENNETT** (Brookes Institute for Advanced Studies, Hellerup, DENMARK)
    e-mail: bennett@nbivms.nbi.dk
19. **Yuri BEREST** (Cornell University, Ithaca, NY, USA)
    e-mail: berest@polygon.math.cornell.edu
20. **Yuriy BERKELA** (Carpathian Biosphere Reserve, Rakhiv,, UKRAINE)
    e-mail: yuri@rakhiv.ukrtel.net
21. **Yuri BESPALOV** (Bogolyubov Institute for Theoretical Physics of NAS of Ukraine,
    Kyiv, UKRAINE) e-mail: mmtpitp@gluk.org
22. **Ayse Humeyra BILGE** (Istanbul Technical University, Istanbul, TURKEY)
    e-mail: bilge@itu.edu.tr
23. **Nicoleta BILA** (Industrial Mathematics Institute, Johannes Kepler University, Linz, AUSTRIA)
    e-mail: bila@indmath.uni-linz.ac.at
24. **Maciej BŁASZAK** (Institute of Physics, A. Mickiewicz University, Poznan, POLAND)
    e-mail: blaszakm@amu.edu.pl
25. **George BOGOSLOVSKY** (Skobeltsyn Institute of Nuclear Physics, Moscow State University,
    Moscow, RUSSIA) e-mail: bogoslov@theory.sinp.msu.ru

26. **Andrey BONDARENKO** (Kyiv Taras Shevchenko University, Kyiv, UKRAINE)
e-mail: bondarenkoa@ukr.net
27. **Vitalij BONDARENKO** (Institute of Mathematics of NAS of Ukraine, Kyiv, UKRAINE)
e-mail: vit-bond@imath.kiev.ua
28. **Luis J. BOYA** (Universidad de Zaragoza, SPAIN)
e-mail: luisjo@unizar.es
29. **Vyacheslav BOYKO** (Institute of Mathematics of NAS of Ukraine, Kyiv, UKRAINE)
e-mail: boyko@imath.kiev.ua
30. **Kirill A. BRONNIKOV** (Center of the Gravitation and Fundamental Metrology, VNIIMS, Moscow, RUSSIA) e-mail: kb@rgs.mccme.ru
31. **Paolo BUDINICH** (International School for Advanced Studies, Trieste, ITALY)
e-mail: fit@ictp.trieste.it
32. **Ivan BURBAN** (Bogolyubov Institute for Theoretical Physics, Kyiv, UKRAINE)
e-mail: mmtpitp@bitp.kiev.ua
33. **Georgy I. BURDE** (Ben-Gurion University, Jacob Blaustein Institute for Desert Research, ISRAEL) e-mail: georg@bgumail.bgu.ac.il
34. **Vladimir BURSKII** (Inst. Appl. Math. Mech. of NAS of Ukraine, Donetsk, UKRAINE)
e-mail: burskii@iamm.ac.donetsk.ua
35. **Robert CARROLL** (University of Illinois, Urbana, USA)

New exact solutions for the heat equation $u_t = u_{xx} + \lambda u^{\frac{n-1}{2}} + \varepsilon u^{\frac{n+1}{2}} + cu + du^{\frac{3-n}{2}}$ are found.

1 Introduction

The nonlinear diffusion equations

$$u_t = u_{xx} + b(u)u_x + c(u), \tag{1}$$

where $u = u(t, x)$, $b(u)$, $c(u)$ are smooth functions, and subscripts denote derivatives with respect to the corresponding variables, play fundamental role in the modelling of various processes of heat conduction, reaction-diffusions, in mathematical biology, and also in many other spheres. Equation (1) generalizes a great number of known nonlinear evolution equations. Thus in particular cases equation (1) is regarded as classical Burgers equation

$$u_t = u_{xx} + \lambda_1 u u_x, \tag{2}$$

and also as Kolmogorov–Piskunov equation

$$u_t = u_{xx} + f(u), \tag{3}$$

where $f(u)$ is a sufficiently smooth function.

It is well known, that nonlocal Cole–Hopf transformation

$$u = -2\mu \frac{v_x}{v}, \qquad v = v(t, x) \tag{4}$$

makes every solution of linear heat conduction equation

$$v_t - \mu v_{xx} = 0 \tag{5}$$

correspond to the particular solution of the equation (2). By these means, the transformation (4) reduces the problem of construction of solutions of the equation (2) to the construction of solutions of linear equation (5).

The conditional symmetries equation (3) was investigated in [1, 2]. The operators of conditional symmetry of this equation were found only in the case when $f(u)$ is a polynomial of 3rd order. All known solutions of the equation (3) that were successfully obtained by means of conditional symmetry operators, have such representation

$$u = k \frac{z_x}{z}, \tag{6}$$

where k is constant, and $z = z(t, x)$ is some arbitrary function.

It should be noticed that group classification of equations (1) was done in [3]. The results concerning conditional symmetries of equation (1) are mentioned in [4]. In [5] wide classes of exact solutions of equation (3) are represented.

A goal of this article is to construct the exact solutions of equation

$$u_t = u_{xx} + \lambda u^{\frac{n-1}{2}} u_x + \varepsilon u^{\frac{n+1}{2}} + cu + du^{\frac{3-n}{2}}, \tag{7}$$

where $\varepsilon = \pm 1$, c, d are arbitrary real numbers. In case $n = 3$ we use transformation (3). The transformation (6) is particular case of transformation

$$u = k\left(\frac{z_x}{z}\right)^{\frac{2}{n-1}}, \tag{8}$$

that is effective in case of arbitrary n. By using the transformation (8) we reduce the problem of constructing of exact solutions of equation (7) to the problem of finding function $z = z(t, x)$. As will be mentioned further, function $z = z(t, x)$ is a solution of system of ordinary differential equations that is easily solved in many cases.

2 The exact solutions of equation (7) for $n = 3$

We construct the exact solutions of equation (7) for $n = 3$

$$u_t = u_{xx} + \lambda u u_x + \varepsilon u^2 + cu + d. \tag{9}$$

By substituting (6) into (9), we obtain

$$(kz_{xt} - kz_{xxx} - ckz_x - dz)z^2 + kz_x(-z_t + (3 - \lambda k)z_{xx} - \varepsilon k z_x)z + (-2k + \lambda k^2) = 0.$$

The variable z will be determined from the conditions of zero expressions at z and z^2 simultaneously. As a result we have

$$kz_{xt} - kz_{xxxx} - ckz_x - dz = 0, \tag{10}$$
$$-z_t + (3 - \lambda k)z_{xx} - \varepsilon k z_x = 0, \tag{11}$$
$$2 - \lambda k = 0. \tag{12}$$

From equation (11) and (12) we find

$$z_t = z_{xx} - \varepsilon k z_x. \tag{13}$$

By substituting into equation (10), we obtain

$$\varepsilon k^2 z_{xx} + ckz_x + dz = 0. \tag{14}$$

Thus, the system (10)–(12) is equivalent to the system (12)–(14). This system can be easily solved. The type of solution depends on roots of characteristic equation

$$\varepsilon k^2 r^2 + ckr + d = 0, \tag{15}$$

that corresponds to linear equation (14). The roots of characteristic equation (15) are $\frac{1}{k}m_1$, $\frac{1}{k}m_2$, where m_1 and m_2 are the roots quadratic equation

$$\varepsilon r^2 + cr + d = 0. \tag{16}$$

We consider tree cases.

a) The roots are real and different. The general solution of equation (14) has such form

$$z = \mu_1(t)\exp\left(\frac{1}{k}m_1 x\right) + \mu_2(t)\exp\left(\frac{1}{k}m_1 x\right),$$

where $\mu_1(t)$, $\mu_2(t)$ are functions of t which have to be found. By using equation (13), we obtain

$$\frac{d\mu_1}{dt} = \frac{1}{k^2}m_1^2\mu_1 - \varepsilon m_1\mu_1, \qquad \frac{d\mu_2}{dt} = \frac{1}{k^2}m_2^2\mu_2 - \varepsilon m_2\mu_2.$$

So,

$$\mu_1 = k_1\exp\left[\left(\frac{1}{k^2}m_1^2 - \varepsilon m_1\right)t\right], \qquad \mu_2 = k_2\exp\left[\left(\frac{1}{k^2}m_2^2 - \varepsilon m_2\right)t\right],$$

and

$$z = k_1\exp\left[\frac{1}{k}m_1 x + \left(\frac{1}{k^2}m_1^2 - \varepsilon m_1\right)t\right] + k_2\exp\left[\frac{1}{k}m_2 x + \left(\frac{1}{k^2}m_2^2 - \varepsilon m_2\right)t\right].$$

Thus we have found such solution of equation (2)

$$u = \frac{k_1 m_1\exp\left[\frac{\lambda}{2}m_1 x + \left(\frac{\lambda^2}{4}m_1^2 - \varepsilon m_1\right)t\right] + k_2 m_2\exp\left[\frac{\lambda}{2}m_2 x + \left(\frac{\lambda^2}{4}m_2^2 - \varepsilon m_2\right)t\right]}{k_1\exp\left[\frac{\lambda}{2}m_1 x + \left(\frac{\lambda^2}{4}m_1^2 - \varepsilon m_1\right)t\right] + k_2\exp\left[\frac{\lambda}{2}m_2 x + \left(\frac{\lambda^2}{4}m_2^2 - \varepsilon m_2\right)t\right]},$$

where k_1, k_2 are arbitrary real constants, that are not equal to zero simultaneously,

$$m_1 = \frac{-c_1 + \sqrt{c^2 - 4\varepsilon d}}{2\varepsilon}, \qquad m_2 = \frac{-c_1 - \sqrt{c^2 - 4\varepsilon d}}{2\varepsilon}.$$

b) The roots are complex numbers. Let $m_1 = \alpha + i\beta$, $m_2 = \alpha - i\beta$. In this case we obtain

$$z = \exp\left[\frac{\lambda}{2}dx + \left(\frac{\lambda^2}{4}(\alpha^2 - \beta^2) - \varepsilon\alpha\right)t\right] \times \left\{k_1\cos\left[\frac{\lambda}{2}\beta x + \left(\frac{\lambda^2}{2}\alpha\beta - \varepsilon\beta\right)t\right] + k_2\sin\left[\frac{\lambda}{2}\beta x + \left(\frac{\lambda^2}{2}\alpha\beta - \varepsilon\beta\right)t\right]\right\},$$

where k_1, k_2 are arbitrary real numbers, that are not equal to zero simultaneously. Thus, the solution of equation (9) has such form

$$u = \frac{\alpha k_1 + \beta k_2)\cos\left[\frac{\lambda}{2}\beta x + \left(\frac{\lambda^2}{2}\alpha\beta - \varepsilon\beta\right)t\right] + (\alpha k_2 - \beta k_1)\sin\left[\frac{\lambda}{2}\beta x + \left(\frac{\lambda^2}{2}\alpha\beta - \varepsilon\beta\right)t\right]}{k_1\cos\left[\frac{\lambda}{2}\beta x + \left(\frac{\lambda^2}{2}\alpha\beta - \varepsilon\beta\right)t\right] + k_2\sin\left[\frac{\lambda}{2}\beta x + \left(\frac{\lambda^2}{2}\alpha\beta - \varepsilon\beta\right)t\right]},$$

where

$$\alpha + i\beta = \frac{-c + \sqrt{c^2 - 4\varepsilon d}}{2\varepsilon}, \qquad \alpha - i\beta = \frac{-c - \sqrt{c^2 - 4\varepsilon d}}{2\varepsilon}.$$

c) The roots are equal. In this case $c^2 - 4\varepsilon d = 0$, and thus $d = \frac{c^2}{4\varepsilon}$, $m_1 = m_2 = -\frac{c}{2\varepsilon}$. Function z has such form

$$z = \exp\left[-\frac{\varepsilon\lambda c}{4}x + \left(\frac{\lambda^2 c^2}{16} + \frac{c}{2}\right)t\right]\left\{k_1 x + \left(-\frac{\varepsilon\lambda c}{2}k_1 - \frac{2\varepsilon}{\lambda}k_1\right)t + k_0\right\},$$

where k_1, k_2 are arbitrary real numbers, that are not equal to zero simultaneously. We obtain such solution of equation (9)

$$u = \frac{2}{\lambda}\frac{-\frac{\varepsilon\lambda c}{4}\left\{k_1 x + \left(-\frac{\varepsilon\lambda c}{2}k_1 - \frac{2\varepsilon}{\lambda}k_1\right)t + k_0\right\} + k_1}{k_1 x + \left(-\frac{\varepsilon\lambda c}{2}k_1 - \frac{2\varepsilon}{\lambda}k_1\right)t + k_0}.$$

In particular, if $c = 0$ then the solution has such form

$$u = \frac{2k_1}{\lambda k_1 x - 2\varepsilon k_1 t + \lambda k_0}.$$

Let us consider two separate cases.

a) $c = 0$, $\varepsilon < 0$. The equation (16) has two real and different roots

$$m_1 = \sqrt{-\varepsilon d}, \qquad m_2 = -\sqrt{-\varepsilon d}.$$

Thus the solution of equation (9) has form

$$u = \frac{k_1 m_1 \exp\left[\frac{\lambda m_1}{2}x + \left(-\frac{\varepsilon\lambda^2 d}{4} + \varepsilon m_2\right)t\right] + k_2 m_2 \exp\left[\frac{\lambda m_1}{2}x + \left(-\frac{\varepsilon\lambda^2 d}{4} + \varepsilon m_1\right)t\right]}{k_1 \exp\left[\frac{\lambda m_1}{2}x + \left(-\frac{\varepsilon\lambda^2 d}{4} + \varepsilon m_2\right)t\right] + k_2 \exp\left[\frac{\lambda m_2}{2}x + \left(-\frac{\varepsilon\lambda^2 d}{4} + \varepsilon m_1\right)t\right]}.$$

b) $c = 0$, $\varepsilon d > 0$. The equation (16) has two complex roots

$$m_1 = i\sqrt{\varepsilon d}, \qquad m_2 = -i\sqrt{\varepsilon d}.$$

Thus the solution of equation (9) has form

$$u = \frac{k_2\sqrt{\varepsilon d}\cos\left[\frac{\lambda}{2}\sqrt{\varepsilon d}x - \varepsilon\sqrt{\varepsilon d}t\right] - k_1\sqrt{\varepsilon d}\sin\left[\frac{\lambda}{2}\sqrt{\varepsilon d}x - \varepsilon\sqrt{\varepsilon d}t\right]}{k_1\cos\left[\frac{\lambda}{2}\sqrt{\varepsilon d}x - \varepsilon\sqrt{\varepsilon d}t\right] + k_2\sqrt{\varepsilon d}\sin\left[\frac{\lambda}{2}\sqrt{\varepsilon d}x - \varepsilon\sqrt{\varepsilon d}t\right]}.$$

3 The exact solutions of equation (7) for arbitrary n

Let us consider equation (7) for arbitrary n and for $d = e$

$$u_t = u_{xx} + \lambda u^{\frac{n-1}{2}}u_x + \varepsilon u^{\frac{n+1}{2}} + cu. \tag{17}$$

Substituting (8) into equation (17), we obtain such system for finding variable z

$$\frac{2}{n-1}z_x z_{xt} - \frac{2(3-n)}{(n-1)^2}z_{xx}^2 - \frac{2}{n-1}z_x z_{xx} - cz_x^2 = 0, \tag{18}$$

$$z_t = \left(\frac{n+3}{n-1} - \lambda k^{\frac{n-1}{2}}\right)z_{xx} - \varepsilon\frac{n-1}{2}k^{\frac{n-1}{2}}z_x, \tag{19}$$

$$k^{\frac{n-1}{2}} = \frac{n+1}{\lambda(n-1)}. \tag{20}$$

Solving system (18)–(20), we find such solution for equation (17)

$$u = \left[\frac{n+1}{\lambda(n-1)}\right]^{\frac{2}{n-1}} \frac{\exp\left[-\frac{2\varepsilon\lambda c}{n+1}x + \left(\frac{4\lambda^2 c^2}{(n+1)^2} + c\right)t\right]}{\left\{-\frac{\varepsilon(n+1)}{\lambda(n-1)c}\exp\left[-\frac{\varepsilon\lambda c(n-1)}{n+1}x + \left(\frac{2\lambda^2 c^2}{(n+1)^2} + \frac{c}{2}\right)(n-1)t\right] + c_1\right\}^{\frac{2}{n-1}}},$$

where c, c_2 are arbitrary constants.

This approach can be used for finding the exact solutions of more general type of reaction-diffusion equation that will be done in the next articles.

We present exact solitary wave solutions for a class of nonlinear heat equations and for coupled system of heat equations.

1 Introduction

A great number of mathematical models in thermomechanics, chemistry, biology, ecology, etc., are formulated using nonlinear heat equations. Some of these models admit exact solutions which play fundamental role for theory of the related equations and have large application values, refer, e.g., to monograph [1].

There are well-known regular approaches for searching exact solutions of partial differential equations (see, e.g., monographs [2–4]) which make it possible to find specific changes of dependent and independent variables (Ansätze) reducing equations of interest to simpler ones. Usually the possibility of such reduction is caused by the symmetry (classical Lie [2], conditional [3], Lie–Bäcklund [4], etc.) of the related equations.

In the present paper we find exact solutions for the nonlinear heat equations

$$u_t - u_{xx} = f(u) \tag{1}$$

and for coupled systems of heat equations

$$\begin{aligned} &u_t - u_{xx} = f(u,v),\\ &v_t - v_{xx} = g(u,v), \end{aligned} \tag{2}$$

where $f(u)$, $f(u,v)$ and $g(u,v)$ are functions of dependent variables specified in the following. To find these solutions we use the "universal" Ansatz of the following general form

$$u = (z_x)^k \varphi(z) \tag{3}$$

and

$$v = (z_x)^k \xi(z), \tag{4}$$

where the new variable z is a function of t and x.

The Ansätze (3), (4) appear to be very effective tools for reduction of equations (1), (2) and many others, refer e.g. to [4, 5]. In particular, they enable making a wide class of reductions caused by classical Lie symmetries and conditional symmetries as well [4].

In this paper we use Ansätze (3), (4) to find special exact solutions of equations (1), (2), namely, solitary wave solutions. We present also some other solutions which appear in our analysis. To achieve our goals we select special classes of equations (1), (2) which can be reduced using the mentioned Ansätze.

2 Reduction of equations (1) with cubic nonlinearity

We start with equations (1) with the cubic nonlinearities, i.e.,

$$u_t - u_{xx} = -2u^3. \tag{5}$$

Exact solutions for (5) as well as for equation (1) with cubic polynomial nonlinearity were found in [7, 8] using the conditional symmetry approach. Here we find these solutions directly using Ansatz (3). The results presented in this section will be used to construct solutions for the system of heat equations (2).

Using Ansatz (3) with $k = 1$ we find

$$\begin{aligned} &u_t = z_{tx}\varphi + z_x z_t \varphi_z, \qquad u_x = z_{xx}\varphi + z_x^2\varphi_z, \\ &u_{xx} = z_{xxx}\varphi + 3z_x z_{xx}\varphi_z + z_x^3\varphi_{zz}, \qquad u^3 = z_x^3\varphi^3. \end{aligned} \tag{6}$$

Substituting (6) into (5) and equating coefficients for φ and φ' we come to the following reduced equations

$$z_{tx} - z_{xxx} = 0, \qquad z_t - 3z_{xx} = 0, \tag{7}$$

$$\varphi_{zz} = 2\varphi^3. \tag{8}$$

Up to constant multiplier and shifts of t and x solution of (7) have the form

$$z = 6t + x^2. \tag{9}$$

Solutions of equations (8) can be expressed via Jacobi elliptic functions. In paper [5] we present an infinite set of such solutions (and solutions for equation (1) with cubic polynomial nonlinearities as well) in explicit form.

Thus the Ansatz (3) makes it possible to find exact solutions for equation (5) in the form

$$u = 2x\varphi\left(6t + x^2\right),$$

where $\varphi(z)$ is an elliptic function satisfying (8).

In the following Section we generalize the reduction scheme (5)–(9) to find exact solutions for systems of heat equations (2).

3 Reduction and exact solutions for equations (2)

Consider a subclass of equations (2) where f and g are homogeneous functions of order 3, i.e.,

$$f(\lambda u, \lambda v) = \lambda^3 f(u, v), \qquad g(\lambda u, \lambda v) = \lambda^3 g(u, v). \tag{10}$$

To find exact solutions of these equations we need nothing but a direct generalization of the procedure described in the previous Section. Indeed, all such equations can be reduced to systems of ordinary differential equations using the Ansätze (3), (4) for $k = 1$. In analogy with (5)–(9) we obtain

$$\begin{aligned} &u = 2x\varphi\left(6t + x^2\right), \qquad v = 2x\xi\left(6t + x^2\right), \\ &\varphi'' = f(\varphi, \xi), \qquad \xi'' = g(\varphi, \xi). \end{aligned} \tag{11}$$

Thus to find exact solutions for system (2), (10) it is sufficient to solve the system of ordinary differential equations (11). For some particular form of functions f and g this system can be integrated in quadratures. Here we consider three examples.

1. Let $f = 2\left(u^3 - 3u^2v + 2uv^2\right)$, $g = 0$. Then equations (11) admit the following particular solutions: $\varphi = 1 - \tanh(z)$, $\xi = 1$. Using them we come to the following solutions for the related equations (2)

$$u = 2x\left(1 - \tanh\left(x^2 + 6t\right)\right), \qquad v = 2x. \tag{12}$$

For any finite interval $x_0 < x < x_1$ solutions (12) are bounded. Moreover, the pattern u has a solitary wave sharp. The plot of function u (12) is given in Fig. 1.

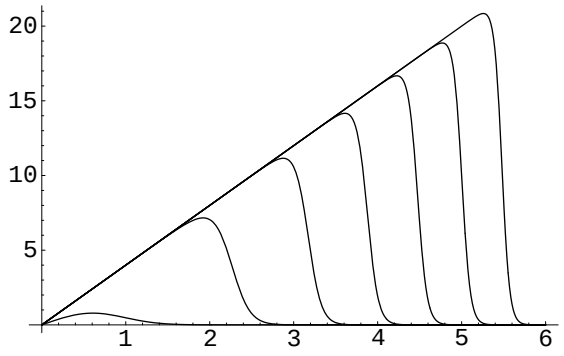

Figure 1. Solutions u (12) for $t = 0, -1/6, -1/3, -1/2, -3/2, -5/6, -1$.

We see that when the time variable t runs from $t = -1$ to $t = 0$ our solitary wave moves from the point $x = 5.5$ to $x = 0.6$ and its amplitude decreases.

2. Consider now the system (2) with nonlinearities of the following general form

$$\begin{aligned} f &= \frac{\varepsilon}{2}\left(n^2u^{n+3}v^{-n} - n(2n+m)v^m u^{3-m}\right), \\ g &= \frac{\varepsilon}{2}\left((n+2)^2u^{n+2}v^{1-n} - (n+2)(2n+m+2)v^{m+1}u^{2-m}\right), \end{aligned} \tag{13}$$

where $\varepsilon = \pm 1$, m and n are arbitrary parameters satisfying $m + n \neq 0$, $n \neq 0,\ -2$.

The Ansatz (4) reduces (2), (13) to the following system of ordinary equations

$$\begin{aligned} \varphi'' &= \varepsilon\left(n^2\varphi^{n+3}\xi^{-n} - n(2n+m)\varphi^m\xi^{-m+3}\right), \\ \xi'' &= \varepsilon\left((n+2)^2\varphi^{n+2}\xi^{1-n} - (n+2)(2n+m+2)\xi^{m+1}\varphi^{2-m}\right) \end{aligned}$$

whose solutions for $\varepsilon = -1$ and $\varepsilon = 1$, are expressed via trigonometric and hyperbolic functions respectively. Thus for $\varepsilon = -1$ we come to the following exact solutions for (2), (13)

$$u = \frac{2\mu x}{n+m}\left[\cos\left(\mu\left(6t + x^2\right)\right)\right]^{-\frac{n}{n+m}}, \qquad v = \frac{2\mu x}{n+m}\left[\cos\left(\mu\left(6t + x^2\right)\right)\right]^{-\frac{(2+n)}{n+m}}. \tag{14}$$

For $\frac{n}{n+m} < 0$ and $\frac{2+n}{n+m} < 0$ solutions (14) are bounded on any finite interval $x_0 \leq x \leq x_1$. The plots of these solutions for $n = 2$, $m = -1$ are given in Figs. 2, 3.

If $\varepsilon = 1$ then the related solutions can be found in the form

$$u = \frac{2\mu x}{n+m}\left[\frac{1}{\mathrm{ch}(\mu(6t + x^2))}\right]^{\frac{n}{n+m}}, \qquad v = \frac{2\mu x}{n+m}\left[\frac{1}{\mathrm{ch}(\mu(6t + x^2))}\right]^{\frac{n+2}{n+m}}. \tag{15}$$

For $\frac{n}{n+m} > 0$ and $\frac{n+2}{n+m} > 0$ formulae (15) present solitary waves. We notice that solutions (15) are not of plane wave type and their amplitudes decrease if t goes from $-t_0$ to 0 ($t_0 > 0$). The plots of these solutions for $n = 1$, $m = 0$ are given in Figs. 4 and 5.

Like in the case of solutions (12), when t runs from $t = -1$ to $t = 0$, our solitary waves move from the point $x = 2.3$ to $x \approx 0.7$ and their amplitudes decrease. When variable t becomes positive and grows the amplitudes tend to zero.

In plots given by Figs. 2–5 the value of amplitudes decrease with increasing of time variable.

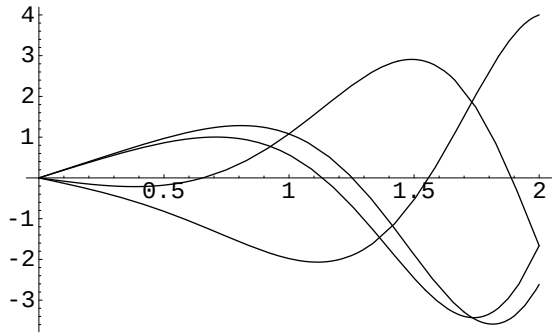

Figure 2. Solutions u (14) for $t = 0, -1/3, -3/2, -1$.

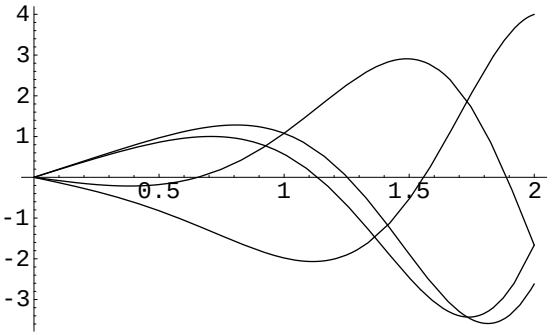

Figure 3. Solutions v (14) for $t = 0, -1/3, -3/2, -1$.

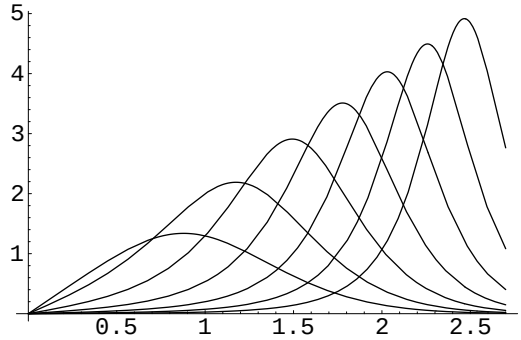

Figure 4. Solutions u (14) for $n = 1$, $m = 0$, and $t = 0, -1/6, -1/3, -1/2, -3/2, -5/6, -1$.

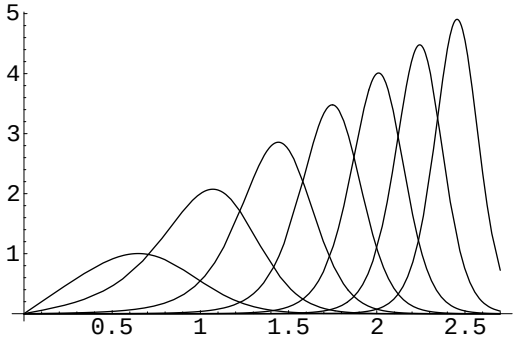

Figure 5. Solutions v (14) for $n = 1$, $m = 0$, $t = 0, -1/3, -3/2, -1$.

4 Solitary wave solutions for equation (1)

Let us return to equation (1) and choose the nonlinearity $f(u)$ in the form

$$f(u) = -\frac{n+1}{n-1}u^n + \lambda_1 u + \lambda_2 u\frac{n+1}{2} + \lambda_3 u^{\frac{3-n}{2}} + \lambda_4 u^{2-n}, \tag{16}$$

where n is an arbitrary parameter.

Reaction-diffusion equations of the general form (1), (16) can be effectively reduced using Ansatz (3) [5]. Choosing $\varphi = z^{-k}$, $k = \frac{2}{n-1}$ we transform (1), (16) to the form

$$z\left(z_x z_{xx} - z_x z_{xxx} - (k-1)z_{xx}^2 - \lambda_4 z^2 - \lambda_3 z_x z\right) = z_x^2(z_x - (2k+1)z_{xx} + \lambda_1 z + \lambda_2 z_x). \tag{17}$$

Equation (17) is homogeneous in dependent variable and is more convenient for searching for exact solutions than the initial equation (1), (16).

Let us search for solutions of (17) in the form $z(t,x) = U(\xi)$ where $\xi = \mu t + x$ and μ is an arbitrary (nonzero) constant. Then we come to the following ordinary differential equation for U

$$\begin{aligned} &U[U'(\mu U'' - U''' - \lambda_3 U) - \lambda_4 U^2 - (k-1)(U'')^2] \\ &\quad = (U')^2[(\mu + \lambda_2)U' + \lambda_1 U - (2k+1)U''], \end{aligned} \tag{18}$$

where $U' = \frac{dU}{d\xi}$.

Using the idea of Fan [9] we express U in the form

$$U = \nu_0 + \nu_1\varphi + \nu_2\varphi^2 + \cdots, \tag{19}$$

where $\nu_0, \nu_1, \dots$ are constants and φ satisfies the equation of the following general form

$$\varphi' = \varepsilon\sqrt{c_0 + c_1\varphi + c_2\varphi^2 + \cdots}. \tag{20}$$

In order (19) to be compatible with (18) we have to equate separately the terms which include odd and even powers of the square root given by (20). As a result we obtain

$$U'(\mu UU'' - \lambda_3 U^2) = (U')^3(\mu + \lambda_2), \tag{21}$$
$$U\big(U'U''' + \lambda_4 U^2 + (k-1)(U'')^2\big) = (U')^2((2k+1)U'' - \lambda_1 U). \tag{22}$$

Dividing any term in (21) by $\mu U^2 U'$ we come to the Riccati equation

$$Y' - \frac{\lambda_2}{\mu}Y^2 = \frac{\lambda_3}{\mu}$$

for $Y = \frac{U'}{U}$, whose general solutions are

$$Y = \sqrt{\frac{-\lambda_3}{\lambda_2}}\tanh\left(\frac{\sqrt{-\lambda_2\lambda_3}}{\mu}\xi + C\right),$$
$$Y = \sqrt{\frac{-\lambda_3}{\lambda_2}}\left(\tanh\left(\frac{\sqrt{-\lambda_2\lambda_3}}{\mu}\xi + C\right)\right)^{-1}, \qquad \text{if} \quad \lambda_2\lambda_3 < 0, \tag{23}$$
$$Y = \sqrt{\frac{\lambda_3}{\lambda_2}}\tan\left(\frac{\sqrt{\lambda_2\lambda_3}}{\mu}\xi + C\right), \qquad \text{if} \quad \lambda_2\lambda_3 > 0, \tag{24}$$
$$Y = -\frac{\mu}{\lambda_2(\xi + C)}, \qquad \text{if} \quad \lambda_3 = 0, \tag{25}$$

where C is the integration constant.

Solutions (23), (24) and (25) are compatible with (22) provided

$$\mu = -\lambda_2, \qquad \lambda_1 = -k\frac{\lambda_3}{\lambda_2}, \qquad \lambda_4 = (1-k)\left(\frac{\lambda_3}{\lambda_2}\right)^2, \qquad \lambda_2\lambda_3 \neq 0$$

and

$$\lambda_1 = \lambda_4 = 0, \qquad \lambda_3 = 0$$

respectively. Using variables

$$\tau = \frac{2}{(n-1)^2}t, \qquad y = \frac{\sqrt{2}}{n-1}x, \qquad \sigma = -\lambda_2(n-1), \qquad \nu = \frac{\lambda_3}{\lambda_2}$$

we can rewrite the related equation (1), (16) as follows:

$$u_\tau - u_{yy} = \left(1 + \nu u^{1-n}\right)\left(-(n+1)u^n + \nu(n-3)u + \sigma u^{\frac{n+1}{2}}\right). \tag{26}$$

The corresponding solutions for equation (26) have the following form

$$u = (-\nu)^{\frac{1}{n-1}}\left(\tanh\left(b\left(y - \frac{\sigma}{\sqrt{2}}t\right) + C\right)\right)^{\frac{2}{n-1}}, \tag{27}$$
$$u = (-\nu)^{\frac{1}{n-1}}\left(\tanh\left(b\left(y - \frac{\sigma}{\sqrt{2}}t\right) + C\right)\right)^{\frac{2}{1-n}}, \tag{28}$$

where $\nu < 0$ and $b = (n-1)\sqrt{\frac{-\nu}{2}}$,

$$u = (\nu)^{\frac{1}{n-1}} \left(\tan\left(b\left(y - \frac{\sigma}{\sqrt{2}} t \right) + C \right) \right)^{\frac{2}{n-1}}, \tag{29}$$

where $\nu > 0$ and $b = (n-1)\sqrt{\frac{\nu}{2}}$, and

$$u = 2^{n-1} \left((n-1)\left(y - \frac{\sigma}{\sqrt{2}} \tau + C \right) \right)^{\frac{2}{1-n}} \tag{30}$$

if $\nu = 0$.

For $\frac{2}{n-2} > 1$ formula (27) presents solitary wave solutions propagating with the velocity $\frac{\sigma}{\sqrt{2}}$. In the case $n = 2$ we come to the bell-shaped solitary wave.

If $\frac{2}{n-2} < -1$ then equation (26) again admits solitary wave solutions which are given by relation (28). In contrast with (14) they are bell-shaped plane waves.

5 Discussion

We present a collection of solitary wave solutions for nonlinear heat equations. All these solutions are obtained using the Ansatz (3), (4).

It is possible to show that all reductions used in the present paper are caused by the conditional symmetry of the related equations (1), (2). Instead of investigation of conditional symmetries we prefer the direct use of the universal Anzätse which seams to be the easiest way to find equations admitting exact solutions of the desired solitary wave type.

Nevertheless the very existence of extended classes of exact solutions for systems of heat equations shows that the problem of classification of conditional symmetries for these systems is quite interesting. We plane to consider this problem elsewhere.

We have solved completely the problem of the description of quasi-linear evolution differential equations in two independent variables that are invariant under $so(3)$ and $sl(2,\mathbb{R})$ Lie algebras.

1 Introduction

The basic idea is to combine the standard Lie algorithm for point symmetries with the equivalence group of the given type of equation in order to give a classification of evolution equations in some canonical form [1].

We consider third-order evolution equations of the type

$$u_t = F(t,x,u,u_x,u_{xx})u_{xxx} + G(t,x,u,u_x,u_{xx}). \tag{1}$$

Hereafter $u = u(t,x)$, F, G are sufficiently smooth functions of the corresponding arguments, $u_t = \frac{\partial u}{\partial t}$, $u_x = \frac{\partial u}{\partial x}$, $u_{xx} = \frac{\partial^2 u}{\partial x^2}$, $u_{xxx} = \frac{\partial^3 u}{\partial x^3}$, $F \neq 0$.

The first step of the algorithm is the determination of the most general form of the infinitesimal symmetry operator admitted by the PDE (1). To this end, we use Lie's method and look for a symmetry generator in the form

$$Q = \tau(t,x,u)\partial_t + \xi(t,x,u)\partial_x + \eta(t,x,u)\partial_u, \tag{2}$$

where τ, ξ, η are arbitrary, real-valued smooth functions defined in some subspace of the space $V = X \otimes \mathbb{R}^1$ of the independent variables $X = \langle t,x\rangle$ and the dependent variable $\mathbb{R}^1 = \langle u\rangle$.

As a result, we find that the operator (2) generates a one-parameter symmetry group of equation (1) if

$$\varphi^t - [\tau F_t + \xi F_x + \eta F_u + \varphi^x F_{u_x} + \varphi^{xx} F_{u_{xx}}]u_{xxx} - \varphi^{xxx}F - \tau G_t - \xi G_x - \eta G_u - \varphi^x G_{u_x} - \varphi^{xx} G_{u_{xx}}\Big|_{u_t = Fu_{xxx}+G} = 0,$$

where

$$\begin{aligned}
&\varphi^t = D_t(\eta) - u_t D_t(\tau) - u_x D_t(\xi),\\
&\varphi^x = D_x(\eta) - u_t D_x(\tau) - u_x D_x(\xi),\\
&\varphi^{xx} = D_x(\varphi^x) - u_{tx} D_x(\tau) - u_{xx} D_x(\xi),\\
&\varphi^{xxx} = D_x(\varphi^{xx}) - u_{xxt} D_x(\tau) - u_{xxx} D_x(\xi)
\end{aligned}$$

and D_t, D_x are operators of total differentiation in t and x respectively.

We then find the following results:

Theorem 1. *The symmetry group of the equation* (1) *is generated by the infinitesimal operators of the form*

$$Q = \tau(t)\,\partial_t + \xi(t,x,u)\partial_x + \eta(t,x,u)\,\partial_u, \tag{3}$$

where τ, ξ, η *are real-valued functions that satisfy the system*

$$\begin{aligned}
&(\tau_t - 3\xi_x - 3u_x\xi_u)F + \tau F_t + \xi F_x + \eta F_{u_x} + (\eta_x + u_x(\eta_u - \xi_x) - u_x^2\xi_u)F_{u_x} + (\eta_{xx}\\
&\qquad + u_x(2\eta_{xu} - \xi_{xx}) + u_x^2(\eta_{uu} - 2\xi_{xu}) - u_x^3\xi_{uu} + u_{xx}(\eta_u - 2\xi_x) - 3u_xu_{xx}\xi_u)F_{u_{xx}} = 0,\\
&-\eta_t + u_x\xi_t - (\eta_u - \tau_t + u_x\xi_u)G + F(\eta_{xxx} + u_x(3\eta_{xxu} - \xi_{xxx}) + 3u_x^2(\eta_{xuu} - \xi_{xxu})\\
&\qquad + u_x^3(\eta_{uuu} - 3\xi_{xuu}) - u_x^4\xi_{uuu} + 3u_{xx}(\eta_{xu} - \xi_{xx}) + 3u_xu_{xx}(\eta_{uu} - 3\xi_{xu})\\
&\qquad - 6u_{xx}u_x^2\xi_{uu} - 3u_{xx}^2\xi_u) + \tau G_t + \xi G_x + \eta G_u + (\eta_x + u_x(\eta_u - \xi_x) - u_x^2\xi_u)G_{u_x}\\
&\qquad + (\eta_{xx} + u_x(2\eta_{xu} - \xi_{xx}) + u_x^2(\eta_{uu} - 2\xi_{xu})\\
&\qquad - u_x^3\xi_{uu} + u_{xx}(\eta_u - 2\xi_x) - 3u_xu_{xx}\xi_u)G_{u_{xx}} = 0.
\end{aligned} \tag{4}$$

As one can see from equation (4) unless F and G are functions of one variable, it is well-night impossible to make the usual step of splitting this equation in terms of powers of the derivative u_x. This is where it is necessary to add a further element into the argument. The idea is simple: given that we are not able to derive the Lie invariance algebra by first obtaining the defining equations form (4), we then begin by specifying a Lie algebra and then requiring that it be symmetry algebra of (1). Given a Lie algebra, we then look at the possible representations of this Lie algebra within the class of operators of the form given in (2), and it is in this step that we make use of the equivalence group of equation (1). This gives us canonical representations of the symmetry algebra candidates. The final step is to calculate the allowed forms for the function F and G for a given canonical representation of our chosen Lie algebra. This procedure yields canonical forms of evolution equations which are inequivalent under point transformations of the equivalence group of equation (1). Then, for each such canonical evolution equation, one can calculate the maximal symmetry algebra.

The above method requires a list of inequivalent Lie algebra presentations (in terms of commutation relations). All simple (and therefore all semi-simple) finite-dimensional real and complex Lie algebras have been classified [2,3]. However, the list of solvable Lie algebras is far from complete, and as far as we can ascertain, they are given in the work of Morozov and Mubarakzyanov and Turkowski [4–10]. The work of Morozov and Mubarakzyanov are, as far as we are aware, not translated from the original Russian. Here, the solvable Lie algebras up to and including dimension six are classified. Our method is constructive in the sense that we are able to use the low-dimensional Lie algebras up to dimension five in order to give our complete point symmetry classification, and we conclude that no non-linear evolution equation of the form (1) has a point-symmetry invariance algebra of dimension greater that five. We note that a classification in terms of contact symmetries has been given by Magadeev [11].

2 Some previous work

The problem of group classification of such equations was discussed by many authors (see for instance [1,12–18]). Work on classification using the equivalence group has been done by Torrisi and his co-workers [20–22]. The methods of Torrisi et al are based on the infinitesimal representation of the equivalence transformations, in contrast to our approach which involves finite forms of the equivalence transformations.

3 Results

In this section we give some results and show how the equivalence group of the equation plays its role in the classification of representation of a given Lie algebra. First, we begin with the description of the equivalence group of equation (1).

Lemma 1. *The maximal equivalence group $\mathcal{E}$ of equation* (1) *reads as*

$$\bar{t} = T(t), \qquad \bar{x} = X(t,x,u), \qquad v = U(t,x,u), \tag{5}$$

where $\dot{T} \neq 0$, $\frac{D(X,U)}{D(x,u)} \neq 0$.

The next step is to give a canonical form (linearization) for a vector field, with respect to the allowed transformations (5). This is given in the following result:

Lemma 2. *There are changes of variables* (5)*, that reduce an operator* (3) *to one of the operators below:*

$$Q = \partial_t, \tag{6}$$
$$Q = \partial_x. \tag{7}$$

Proof. Making the change of variables (5) transforms operator (3) to the following one:

$$Q \to Q' = \tau\dot{T}\partial_{\bar{t}} + (\tau X_t + \xi X_x + \eta X_u)\partial_{\bar{x}} + (\tau U_t + \xi U_x + \eta U_u)\partial_v. \tag{8}$$

Suppose $\tau \neq 0$. Then, choosing in (5) the function T to be a solution of the equation $\dot{T} = \tau^{-1}$ and the functions X and U to be independent fundamental solutions of the first-order PDE

$$\tau Y_t + \xi Y_x + \eta Y_u = 0, \qquad Y = Y(t,x,u),$$

we find that the operator (8) takes the form $Q' = \partial_{\bar{t}}$.

Now suppose $a = 0$. Then $\xi^2 + \eta^2 \neq 0$. If $b \neq 0$, then choosing in (5) a particular solution of PDE $\xi X_x + \eta X_u = 1$ as the function X and a fundamental solution of PDE $\xi U_x + \eta U_u = 0$ as the function U, we transform (8) to become $Q' = \partial_{\bar{x}}$.

If $\xi = 0$, $\eta \neq 0$, then making the change of variables (5) with $\bar{t} = t$, $\bar{x} = u$, $v = x$, we again get the case $\xi \neq 0$.

By the direct calculation we can verify that there is no transformation from $\mathcal{E}$, that reduce operator (6) to the form (7). ■

Example 1. $sl(2,\mathbb{R})$. Now we give an example of the calculations involved. We do this using the Lie algebra $sl(2,\mathbb{R})$ which is the Lie algebra with basis $\langle Q_1, Q_2, Q_3\rangle$ satisfying the commutation relations

$$[Q_1, Q_2] = 2Q_2, \qquad [Q_1, Q_3] = -2Q_3, \qquad [Q_2, Q_3] = Q_1. \tag{9}$$

First, we take one operator from the basis and put it into canonical form. So let us choose Q_3 for this purpose (this is done for purely practical reasons.) By Lemma 2, we can choose Q_3 in one of two canonical forms: $Q_3 = \partial_t$ or $Q_3 = \partial_x$.

We consider in detail the case $Q_3 = \partial_t$. With this choice of Q_3 we proceed to find the allowable forms for Q_3 or Q_3. So put

$$Q_1 = \tau(t)\partial_t + \xi(t,x,u)\partial_x + \eta(t,x,u)\partial_u.$$

The second commutation relation in (9) then implies that

$$\dot{\tau} = 2, \qquad \dot{\xi} = \dot{\eta} = 0.$$

Therefore, $\tau(t) = 2t + c$, $c = \text{const}$ and ξ, η are independent of t. So we take

$$Q_1 = 2t\partial_t + \xi(x,u)\partial_x + \eta(x,u)\partial_u.$$

The next step is to find a canonical form for Q_1 under the equivalence transformations (5). However, we must now use only those equivalence transformations of (5) which preserve the form $Q_3 \to \bar{Q}_3$ with

$$\bar{Q}_3 = \dot{T}\partial_{\bar{t}} + X_t\partial_{\bar{x}} + U_t\partial_v = \partial_{\bar{t}}$$

which yields $\dot{T} = 1$, $X_t = U_t = 0$. Thus we take $T(t) = t$, $X = X(x,u)$, $U = U(x,u)$. Under this type of transformation we find

$$Q_1 \to \bar{Q}_1 = 2\bar{t}\partial_{\bar{t}} + (\xi X_x + \eta X_u)\partial_{\bar{x}} + (\xi U_x + \eta U_u)\partial_v.$$

We now choose X and U so that

$$\xi X_x + \eta X_u = X, \qquad \xi U_x + \eta U_u = 0.$$

This gives us the canonical form

$$\bar{Q}_1 = 2\bar{t}\partial_{\bar{t}} + \bar{x}\partial_{\bar{x}}.$$

This means that we can, up to an equivalence transformation of equation (1), take

$$Q_3 = \partial_t, \qquad Q_1 = 2t\partial_t + x\partial_x.$$

Finally, we need to determine Q_2. We put

$$Q_2 = \alpha(t)\partial_t + \beta(t,x,u)\partial_x + \gamma(t,x,u)\partial_u.$$

The commutation relation $[Q_2, Q_3] = Q_1$ gives

$$\alpha(t) = -t^2 + c, \qquad \beta = -xt + b(x,u), \qquad \gamma = \gamma(x,u).$$

Thus we may take

$$Q_2 = -t^2\partial_t + (b(x,u) - xt)\partial_x + \gamma(x,u)\partial_u.$$

Then we use the relation $[Q_1, Q_2] = 2Q_2$. From this we obtain

$$b(x,u) = m(u)x^3, \qquad \gamma(x,u) = n(u)x^2$$

and we have

$$Q_2 = -t^2\partial_t + \left(m(u)x^3 - xt\right)\partial_x + n(u)x^2\partial_u.$$

All that remains to be done is to find a canonical form for Q_2. We do this using equivalence transformations (5) which leave invariant the form of Q_1, Q_3. These are given by

$$T(t) = t, \qquad X(tx,u) = q(u)x, \qquad U = p(u)$$

with $q(u) \neq 0$ and $\dot{p}(u) \neq 0$. Under this transformation we find

$$\bar{Q}_2 = -\bar{t}^2\partial_{\bar{t}} + \left(\frac{q(u)m(u) + n(u)\dot{q}(u)}{q^3(u)}\bar{x}^3 - \bar{x}\bar{t}\right)\partial_{\bar{x}} + \frac{n(u)\dot{p}(u)}{q^2(u)}\bar{x}^2\partial_v.$$

There are two cases: $n(u) \neq 0$ and $n(u) = 0$. If $n(u) \neq 0$ then we may choose $p(u)$ and $q(u)$ such that

$$\frac{q(u)m(u) + n(u)\dot{q}(u)}{q^3(u)} = 1, \qquad \frac{n(u)\dot{p}(u)}{q^2(u)} = 1$$

which give us

$$\bar{Q}_2 = -\bar{t}^2\partial_{\bar{t}} + \big(\bar{x}^3 - \bar{x}\bar{t}\big)\partial_{\bar{x}} + \bar{x}^2\partial_v.$$

If, however, $n(u) = 0$ then we have

$$\bar{Q}_2 = -\bar{t}^2\partial_{\bar{t}} + \left(\frac{q(u)m(u) + n(u)\dot{q}(u)}{q^3(u)}\bar{x}^3 - \bar{x}\bar{t}\right)\partial_{\bar{x}}.$$

If now $m(u) > 0$ we may choose $m(u) = q^2(u)$ and we find

$$\bar{Q}_2 = -\bar{t}^2\partial_{\bar{t}} + \big(\bar{x}^3 - \bar{x}\bar{t}\big)\partial_{\bar{x}}.$$

If $m(u) < 0$ then we choose $m(u) = -q^2(u)$ and we find

$$\bar{Q}_2 = -\bar{t}^2\partial_{\bar{t}} + \big(-\bar{x}^3 - \bar{x}\bar{t}\big)\partial_{\bar{x}}.$$

Finally, we note that $t \to -t, \quad x \to x, \quad u \to u$ is an equivalence transformation of equation (1), and the last two canonical forms for Q_2 are equivalent under this transformation. Summarizing this calculation, we find that the algebra $sl(2,\mathbb{R})$ has four canonical forms with $Q_3 = \partial_t$:

$$\langle 2t\partial_t + x\partial_x,\ -t^2\partial_t - tx\partial_x + x^2\partial_u,\ \partial_t\rangle,$$
$$\langle 2t\partial_t + x\partial_x,\ -t^2\partial_t + x(x^2 - t)\partial_x,\ \partial_t\rangle,$$
$$\langle 2t\partial_t,\ -t^2\partial_t,\ \partial_t\rangle,$$
$$\langle 2t\partial_t + x\partial_x,\ -t^2\partial_t - xt\partial_x,\ \partial_t\rangle,$$

and these are inequivalent under the equivalence group given by (5). The canonical form $Q_3 = \partial_x$ gives rise to a similar calculation, and three inequivalent representations for the Lie algebra $sl(2,\mathbb{R})$ are found. Other six realizations of the algebra $sl(2,\mathbb{R})$ be able admitted by PDEs of the form (1).

These results are summarized in the following:

Theorem 2. *There exist six inequivalent realizations of the algebra $sl(2,\mathbb{R})$ by operators* (3)*, which are admitted by PDEs of the form* (1)

$$\langle 2t\partial_t + x\partial_x,\ -t^2\partial_t - tx\partial_x + x^2\partial_u,\ \partial_t\rangle, \tag{10}$$
$$\langle 2t\partial_t + x\partial_x,\ -t^2\partial_t + x\big(x^2 - t\big)\partial_x,\ \partial_t\rangle, \tag{11}$$
$$\langle 2x\partial_x - u\partial_u, -x^2\partial_x + xu\partial_u,\ \partial_x\rangle, \tag{12}$$
$$\langle 2x\partial_x - u\partial_u,\ \big(u^{-4} - x^2\big)\partial_x + xu\partial_u,\ \partial_x\rangle, \tag{13}$$
$$\langle 2x\partial_x - u\partial_u,\ -\big(u^{-4} + x^2\big)\partial_x + xu\partial_u,\ \partial_x\rangle, \tag{14}$$
$$\langle 2x\partial_x,\ -x^2\partial_x,\ \partial_x\rangle. \tag{15}$$

The forms of the functions F, G determining the corresponding invariant equations are given in Table 1, where $\tilde{F}$, $\tilde{G}$ are arbitrary functions.

Table 1.

$sl(2,\mathbb{R})$	F	G
(10)	$x\tilde{F}(\omega,v)$, $\omega=2u-xu_1$, $v=2u-x^2u_{xx}$	$\frac{u_x^2}{4}+x^{-2}\tilde{G}(\omega,v)$
(11)	$x^{-3}u_x^{-4}\tilde{F}(\sigma,u)$, $\sigma=u_{xx}u_x^{-2}+3x^{-1}u_x^{-1}$	$-\frac{x^{-2}\omega}{4}+x^{-2}\left(\frac{9\sigma}{\omega^2}-\frac{12}{\omega^3}\right)\tilde{F}(u,\sigma)+\frac{1}{x^2\omega}\tilde{G}(u,\delta)$, $\omega=xu_x$, $\delta=u_{xx}u_x^{-2}-3x^{-1}u_x^{-1}$, $\sigma=u_{xx}^{-1}u_x^2-\frac{xu_x}{3}$
(12)	$u^{-6}\tilde{F}(t,\omega)$, $\omega=u^{-5}u_{xx}-2u^{-6}u_x^2$	$u\tilde{G}(t,\omega)+(12u^{-9}u_x^3-9u^{-8}u_xu_{xx})\tilde{F}(t,\omega)$
(13)	$\frac{u^{-6}}{(1+4\omega^2)^{\frac{3}{2}}}\tilde{F}(t,\sigma)$, $\sigma=\frac{2v-10\omega^2-1}{2(1+4\omega^2)^{\frac{3}{2}}}$, $\omega=u^{-3}u_x$, $v=u^{-5}u_{xx}$	$u\tilde{G}(t,\sigma)\sqrt{1+4\omega^2}-u\Big[12\sigma^2\omega\sqrt{1+4\omega^2}+21\sigma\omega+\frac{15}{2}\frac{\omega+6\omega^3}{(1+4\omega^2)^{\frac{3}{2}}}\Big]\tilde{F}(t,\sigma)$
(14)	$\frac{u^{-6}}{(4\omega^2-1)^{\frac{3}{2}}}\tilde{F}(t,\sigma_1)$ if $4\omega^2>1$, $\omega=u^{-3}u_x$, $v=u^{-5}u_{xx}$, $\sigma_1=\frac{2v-10\omega^2-1}{2(4\omega^2-1)^{\frac{3}{2}}}$	$u\tilde{G}(t,\sigma_1)\sqrt{4\omega^2-1}-u\Big[12\sigma_1^2\omega\sqrt{4\omega^2-1}+21\sigma_1\omega+\frac{15}{2}\frac{6\omega^3-\omega}{(1-4\omega^2)^{\frac{3}{2}}}\Big]\tilde{F}(t,\sigma)$
	$\frac{u^{-6}}{(1-4\omega^2)^{\frac{3}{2}}}\tilde{F}(t,\sigma_2)$ if $4\omega^2<1$, $\omega=u^{-3}u_x$, $v=u^{-5}u_{xx}$, $\sigma_2=\frac{2v-10\omega^2-1}{2(1-4\omega^2)^{\frac{3}{2}}}$	$u\tilde{G}(t,\sigma_2)\sqrt{1-4\omega^2}-u\Big[12\sigma_2^2\omega\sqrt{1-4\omega^2}+21\sigma_2\omega+\frac{15}{2}\frac{6\omega^3-\omega}{(1-4\omega^2)^{\frac{3}{2}}}\Big]\tilde{F}(t,\sigma_2)$
(15)	$u_x^{-3}\tilde{F}(t,u)$	$-\frac{3}{2}\frac{u_{xx}^2}{u_x^4}\tilde{F}(t,u)+\tilde{G}(t,u)$

Theorem 3. *There exists only one realization of the algebra so*(3) *by operators of the form* (2) *which is an invariance algebra of* (1)*:*

$$\langle\partial_x,\ \tan u\sin x\partial_x+\cos x\partial_u,\ \tan u\cos x\partial_x-\sin x\partial_u\rangle. \tag{16}$$

Furthermore, the most general form of the functions F, G allowing for PDE (1) *to be invariant under the above realization is given by*

$$F=\frac{\sec^3 u}{(1+\omega^2)^{3/2}}\tilde{F}(t,\psi),$$
$$G=\left[9\omega\psi\tan u-3\omega\psi^2(1+\omega^2)^{1/2}+\frac{\omega(1+2\omega^2)}{(\omega^2+1)^{3/2}}-\frac{\omega(5+6\omega^2)\tan^2 u}{(\omega^2+1)^{3/2}}\right]\tilde{F}(t,\psi)$$
$$+(\omega^2+1)^{1/2}\tilde{G}(t,\psi),$$

where we have used the notation

$$\omega=u_x\sec u,\qquad \psi=\frac{u_{xx}\sec^2 u+(1+2\omega^2)\tan u}{(1+\omega^2)^{3/2}}.$$

Provided the function $\tilde{G}$ is arbitrary, the realization (16) *is the maximal symmetry algebra of the corresponding equation* (1)*.*

Our approach is, as we have demonstrated, a combination of the Lie point symmetry analysis and an exploitation of the equivalence group of the equation to give possible canonical forms for the various Lie algebras. Each representation of the Lie algebra is then tested as a symmetry algebra, and is discarded if it gives no result (by which we mean, amongst other things, that the equation admitting a given representation as symmetry algebra must have $F\neq 0$ in (1)).

The present method gives a complete point-symmetry classification of (1), so that any evolution equation of the form is necessarily point-equivalent under the transformations (5) to one of the canonical forms for equation (1).

Nonlocal Symmetry and Integrable Classes of Abel Equation

Vyacheslav M. BOYKO

Institute of Mathematics of NAS of Ukraine, 3 Tereshchenkivs'ka Str., 01601 Kyiv-4, Ukraine
E-mail: *boyko@imath.kiev.ua*

We suggest an approach for description of integrable cases of the Abel equations using the procedure of increasing the order and equivalence transformations for the induced second-order equations.

A diversity of methods were developed to date for finding solutions of nonlinear ordinary differential equations (ODE). Everybody who encounters integration of a particular ODE uses, as a rule, the accumulated databases (or reference books) of the classes of ODE and methods for their integration (e.g. [12, 19]). But if an ODE does not belong to any of the described classes then it does not mean that there is no approaches for finding solutions of this ODE in the closed form.

The symmetry approach is one of the most algorithmic approaches for integration and lowering of the order of ODE that admit a certain nontrivial symmetry (see e.g. Lie's book [13], the books [10, 17, 18] and review papers [10, 25]). In the framework of the symmetry approach (and its modifications) it is possible to obtain many of the known classes of integrable ODE. However, the needs of the applications stimulate new research into development of new methods for construction of ODE solutions in the closed form. The papers [2–10, 14–16, 18–25] may give an idea of current developments and directions of research in the field of symmetry (algebraic) methods for investigation of ODE.

In this paper we study Abel equations of the first and the second kind [1, 12, 19]

$$\dot p = p^3 f_4(y) + p^2 f_3(y) + p f_2(y) + f_1(y), \tag{1}$$

$$\dot p (p + f_0(y)) = p^3 f_4(y) + p^2 f_3(y) + p f_2(y) + f_1(y), \tag{2}$$

where $p = p(y)$, $\dot p = \frac{dp}{dy}$, f_i, $i = 0, \dots, 4$, are arbitrary smooth functions (with f_1, f_2, f_3, f_4 not identically vanishing simultaneously). Equations (1), (2) along with the Riccati equation are among the "simplest" nonlinear first-order ODE that have extensive applications. At the same time the problem of description of integrable classes of these equations stays within the focus of current research, and was previously considered in many papers (see e.g. [5–8, 16, 19, 20, 22–24].

Note that the Abel equations of the first and the second kind (1), (2) are related with each other by a local change of variables (namely, the equation (2) can be reduced to the form (1) by means of the change of variables $p = 1/v(y) - f_0$). Besides, the well-known Riccati equation is a partial case of equation (1).

The problem of finding Lie symmetries for the first-order ODE is equivalent to finding solutions for these equations, and for this reason the direct application of the Lie method is complicated in the general case. On of the well-known approaches in the cases when for a given ODE it is not feasible (or not effective) to apply the Lie method directly, is increasing of the order of the ODE under consideration (in particular, to obtain a second-order ODE related to the respective ODE by a change of variables). For examples of utilisation of such approach we can refer to papers [2–6, 9, 14–16]. In such cases, if the "induced" equation of a higher order admits a non-trivial Lie symmetry (that generated a non-local symmetry for the initial equation), we can speak of so-called hidden symmetries for an initial equation (for more details see [2–4]).

Further we will consider the following second-order ODE

$$\ddot{y} = \dot{y}^4 f_4(y) + \dot{y}^3 f_3(y) + \dot{y}^2 f_2(y) + \dot{y} f_1(y), \tag{3}$$

$$\ddot{y}(\dot{y} + f_0(y)) = \dot{y}^4 f_4(y) + \dot{y}^3 f_3(y) + \dot{y}^2 f_2(y) + \dot{y} f_1(y), \tag{4}$$

where $y = y(x)$, $\dot{y} = \frac{dy}{dx}$, $\ddot{y} = \frac{d^2y}{dx^2}$, related to the Abel equations (1) and (2).

The substitution $\dot{y} = p(y)$ reduces equations (3) and (4) respectively to the Abel equations (1) and (2) (reduction of the order for equations (3) and (4)). Such reduction is induced by the Lie operator $X_1 = \partial_x$ (that corresponds to invariance of equations (3) and (4) with respect to translations by the variable x). This is exactly the fact that explains why we consider equations (3) and (4).

In the case when (3) or (4) are invariant with respect to another operator (that is when (3) or (4) admit two-dimensional Lie algebras), then equations (3) and (4) are integrable in the framework of the Lie approach. And in this way we can obtain exact solutions of the equations (1) and (2) respectively.

Further we will consider only the equation (4) (since equations (1)–(4) are interconnected – see Remark 3). Let (4) admit a two-dimensional Lie algebra

$$L = \langle X_1, X_2 \rangle, \qquad X_1 = \partial_x, \qquad X_2 = \xi(x,y)\partial_x + \eta(x,y)\partial_y. \tag{5}$$

We will consider a problem of description of inequivalent equations (4) that are invariant with respect to two-dimensional Lie algebras of the form (5) (non-equivalent realisations of the operator X_2 in the algebra (5) will determine canonical representatives for equation (4)).

It is well-known that any two-dimensional Lie algebra in the general case, by means of choosing the basis operators X_1 and X_2 in an appropriate manner, may be reduced to four nonequivalent cases (see e.g. [13,17]). In the framework of our problem additional cases arise as we have fixed the form of the operator X_1.

So, it is quite straightforward to show that equation (4) may admit a two-dimensional Lie algebra (5) only of one of the following types:

1. $[X_1, X_2] = 0, \quad \operatorname{rank} L = 1;$
2. $[X_1, X_2] = 0, \quad \operatorname{rank} L = 2;$
3. $[X_1, X_2] = X_1, \quad \operatorname{rank} L = 1;$
4. $[X_1, X_2] = X_1, \quad \operatorname{rank} L = 2;$
5. $[X_1, X_2] = X_2, \quad \operatorname{rank} L = 1;$
6. $[X_1, X_2] = X_2, \quad \operatorname{rank} L = 2.$ (6)

Further, utilising classification of two-dimensional algebras (6), we obtain that equation (4) may admit only the following realisations of two-dimensional Lie algebras (5):

1. $X_1 = \partial_x, \qquad X_2 = \xi(y)\partial_x, \qquad \xi(y) \not\equiv \text{const};$
2. $X_1 = \partial_x, \qquad X_2 = \xi(y)\partial_x + \eta(y)\partial_y,$
   $\xi(y) \not\equiv \text{const or } \xi(y) \equiv 0, \quad \eta(y) \neq 0;$
3. $X_1 = \partial_x, \qquad X_2 = (x + \xi(y))\partial_x, \qquad \xi(y) \not\equiv \text{const or } \xi(y) \equiv 0;$
4. $X_1 = \partial_x, \qquad X_2 = (x + \xi(y))\partial_x + \eta(y)\partial_y,$
   $\xi(y) \not\equiv \text{const or } \xi(y) \equiv 0, \quad \eta(y) \neq 0;$
5. $X_1 = \partial_x, \qquad X_2 = e^x \xi(y)\partial_x, \qquad \xi(y) \not\equiv 0;$
6. $X_1 = \partial_x, \qquad X_2 = e^x(\xi(y)\partial_x + \eta(y)\partial_y), \qquad \eta(y) \neq 0.$ (7)

It is clear that using these realisations we can describe equations of the form (4) that are invariant with respect to two-dimensional Lie algebras (similarly as we have discussed in [22]). However, this way is too cumbersome, and thus obtained types of equations (4) will be quite complicated (functions f_i, $i = 0, \dots, 4$ in (4) will be expressed through coefficients of the operator X_2 from realisations (7)).

It is straightforward to show that the most general transformations that preserve the form of the operator X_1 we look as follows:

$$t = x + \omega(y), \qquad u = g(y), \tag{8}$$

where $\omega(y)$, $g(y)$ are arbitrary smooth functions, $g(y) \not\equiv \text{const}$.

After substitution (8) equation (4) takes the form

$$\begin{aligned}\ddot{u}((1-\omega' f_0)\dot{u} + f_0 g')g'^2 = {} & \big(f_4 - \omega''(1-\omega' f_0) - \omega' f_3 + \omega'^2 f_2 - \omega'^3 f_1\big)\dot{u}^4 \\ & + \big(g' f_3 - \omega'' g' f_0 + g''(1-\omega' f_0) - 2\omega' g' f_2 + 3\omega'^2 g' f_1\big)\dot{u}^3 \\ & + \big(g'^2 f_2 + g'' g'^2 f_0 - 3\omega' g'^2 f_1\big)\dot{u}^2 + f_1 g'^3 \dot{u},\end{aligned} \tag{9}$$

where $\omega' = \frac{d\omega}{dy}$, $\omega'' = \frac{d^2\omega}{dy^2}$, $g' = \frac{dg}{dy}$, $g'' = \frac{d^2 g}{dy^2}$ (in addition in (9) all functions of the variable y should be expressed as functions of the variable u).

With $(1 - \omega' f_0) \not\equiv 0$ equation (9) belongs again to the class of equations (4).

Remark 1. With $(1 - \omega' f_0) \equiv 0$ after the substitution (8), equation (4) is transformed to the equation (3), that is reduced to the Abel equation of the first kind (1).

Remark 2. It is possible to regard that $(1 - \omega' f_0) \not\equiv 0$ for the equation (4) as a result of the substitution (8) (we attain that by combination of transformations (8)).

Thus (8) are equivalence transformations for (4), and, besides, these transformations preserve the form of the operator $X_1 = \partial_x$ in the algebra (5).

Remark 3. So, the transformations (8) are equivalence transformations for the class of equations (3)–(4). Moreover, if we prolongate these transformations for $\dot{u} = p$ then these transformations form an equivalence transformation group for (1)–(2).

Thus, by means of transformations (8), realisations (7) of the algebra (5) may be reduced to the simplest canonical form. The transformations (8) in that process will not take us out of the class of equations (4).

By means of transformations (8) the realisations (7) of two-dimensional Lie algebras (5) admitted for equation (4) are reduced to the following canonical realisations:

$$\begin{aligned}
&1.\ X_1 = \partial_x, && X_2 = y\partial_x;\\
&2.\ X_1 = \partial_x, && X_2 = \partial_y;\\
&3.\ X_1 = \partial_x, && X_2 = x\partial_x;\\
&4.\ X_1 = \partial_x, && X_2 = x\partial_x + y\partial_y;\\
&5.\ X_1 = \partial_x, && X_2 = e^x\partial_x;\\
&6.\ X_1 = \partial_x, && X_2 = e^x(\partial_x + \partial_y).
\end{aligned} \tag{10}$$

In accordance to (10) we obtain the following integrable cases for equation (4) that are non-equivalent with respect to (8):

1. $\ddot{y} = \alpha(y)\dot{y}^3$;

2. $\ddot{y}(\dot{y}+e)=d\dot{y}^4+c\dot{y}^3+b\dot{y}^2+a\dot{y}$;

3. $\ddot{y}=\alpha(y)\dot{y}^2$;

4. $y\ddot{y}(\dot{y}+e)=d\dot{y}^4+c\dot{y}^3+b\dot{y}^2+a\dot{y}$;

5. $\ddot{y}(\dot{y}+\beta(y))=\alpha(y)\dot{y}^3+(1-\alpha(y)\beta(y))\dot{y}^2-\beta(y)\dot{y}$;

6. *a)* $f_0=0$:

$$\ddot{y}=de^y\dot{y}^3+(-3de^y+c)\dot{y}^2+(-de^y-(2c+1)+be^{-y})\dot{y}$$
$$+(-de^y+(c+1)-be^{-y}+ae^{-2y});$$

b) $f_0\neq 0$:

$$\ddot{y}(\dot{y}+\alpha(y))=-\dot{y}^3+(1-\alpha(y))\dot{y}^2+\alpha(y)\dot{y}, \tag{11}$$

where $\alpha(y)$, $\beta(y)$ are arbitrary smooth functions, a, b, c, d, e are constants.

The case 6a in (11) may be simplified by means of the substitution $t=x$, $u=e^y$ (see (8) and (9)).

Equations (11) determine non-equivalent cases of the form (4) that admit two-dimensional algebras (10) up to equivalence transformations (8).

Thus, summarising the above, we come to the following scheme for integration of the Abel equation (2):

- we increase the order of equation (2), considering a second-order equation (4);
- if a corresponding equation (4) admits a two-dimensional Lie algebra, then we reduce this algebra to one of the canonical forms (10), and thus the equation is reduced to the respective canonical forms (11);
- we integrate the canonical form (11);
- making reverse changes of variables we obtain the solution of the Abel equation (2).

It is obvious from the above that there is an alternative way for generation of new integrable cases of the Abel equation based on utilisation of the relation between the Abel equations of the first and the second kind, and relation between the equations (3) and (4) by means of the transformations (8). Thus, starting from some integrable Abel equation (that is of such equation for which the solution is known) it is possible to obtain new integrable cases of the Abel equations (solutions of these equations will be related through transformations (8)). It would be possible to use for this purpose even the well-known Riccati equation that is a partial case of the equation (1) (for generation of integrable Riccati equations an approach that is proposed in [20] may be used).

We hope that new results for classification of integrable classes of ODE may be obtained also using our classification of inequivalent realizations of real low-dimensional Lie algebras [21].

On Equivariant Boundary Value Problems

Vladimir P. BURSKII

Institute of Applied Mathematics and Mechanics, 74 Luxemburg Str., 83114 Donetsk, Ukraine
E-mail: *burskii@iamm.ac.donetsk.ua*

We describe an investigation method of general equivariant boundary value problem for PDE of general form in a domain and show how it works for the case of simplest group $O(n, \mathbb{R})$.

1 Solvability conditions of equivariant expansion

Let $\Omega \subset \mathbb{R}^n$ be a domain, $\mathcal{L} = \sum\limits_{|\alpha| \le m} a_\alpha(x) D^\alpha$ be some arbitrary differential operation with smooth coefficients $a_\alpha(x)$, $\mathcal{L}^+$ be a formally adjoint differential operation. Let L_0, L_0^+ be minimal operators (i.e., for example, $D(L_0)$ is the clozure of $C_0^\infty(\Omega)$ in the norm of the graph $\|u\|_L^2 = \|u\|_{L_2(\Omega)}^2 + \|Lu\|_{L_2(\Omega)}^2$), and L, L^+ be maximal expansions of $\mathcal{L}, \mathcal{L}^+$ in the space $L_2(\Omega)$ respectively (i.e. $L = (L_0^+)^*$, $L^+ = (L_0)^*$), $\tilde{L} = L|_{D(\tilde{L})}$ where $D(\tilde{L})$ is the clozure of $C^\infty(\bar{\Omega})$ in the norm of the graph $\|u\|_L$ and it is analogous for $\tilde{L}^+$.

M.Yo. Vishik introduced the conditions:

V_1) the operator L_0: $D(L_0) \to L_2(\Omega)$ has a continuous left-inverse,

V_2) the operator L_0^+: $D(L_0^+) \to L_2(\Omega)$ has a continuous left-inverse

and proved that

1) these conditions are necessary and sufficient for the existence of a solvable expansion L_B: $D(L_B) \to L_2(\Omega)$, (that is $D(L_0) \subset D(L_B)$, $\exists\, L_B^{-1}$: $L_2(\Omega) \to D(L_B)$);

2) under conditions V_1), V_2) for any solvable expansion L_B the following decomposition of the domain $D(L)$ is valid: $D(L) = D(L_0) + \ker L + B$, and L: $B \to \ker L^+$ is an isomorphism.

Let G be some Lie group, smoothly acting in the closed domain $\bar{\Omega}$. It means, that there is a group of diffeomorphisms U_g: $\bar{\Omega} \ni x \to g \cdot x = U_g(x) \in \bar{\Omega}$ of domain $\bar{\Omega}$ onto itself, group, smoothly depending on an element of G, and mapping $g \to U_g$ is a homomorphism of groups. Thus the contraction of diffeomorphisms U_g on boundary $\partial\Omega$ induces a smooth action of group G on boundary $\partial\Omega$.

The action of group G on domain $\bar{\Omega}$ generates a representation of the group G in function spaces: $(gu)(x) = u(g^{-1}x)$ (homomorphism of group G into group of converted operators). Such representation is induced on spaces $C_0^\infty(\Omega)$, $C^\infty(\Omega)$, $H^m(\Omega)$, $H^{-m}(\Omega)$, $\mathcal{D}'(\Omega)$, $H^{(m)}(\Omega)$, $H^{(-m)}(\Omega)$ and others. Let the differential operation $\mathcal{L}$ be invariant with respect to the action of group G, that is $g(\mathcal{L}u) = \mathcal{L}(gu)$. Then spaces $D(L)$, $D(L_0)$, $C(L)$, $\ker L$ are invariant with respect to the action of the group.

If the action of group preserves the volume of the domain Ω then the scalar product in the space $L_2(\Omega)$ is invariant with respect to the action of group G, and consequently the representation of the group G is unitary in this space. In this case the operation $\mathcal{L}^+$ is also invariant with respect to an action of group G, the spaces $D(L^+)$, $D(L_0^+)$, $C(L^+)$, $\ker L^+$ are invariant.

Boundary value problem

$$Lu = f, \qquad \Gamma u \in B, \tag{1}$$

generated by a subspace $B \subset C(L)$ of the boundary space $C(L) = D(L)/D(L_0)$ we shall name G-**invariant**, if the space B is invariant with respect to the indicated action of group G. A G-invariant boundary value problem we will name **equivariant**, if it is clear what group acts.

If the group G is compact (and is continuous), then, as it is well known, the Hilbert space of representation is decomposed in the direct sum of finite-dimensional invariant subspaces, in which the irreducible representations of group G are induced. And if the group is also commutative, the irreducible representations are one-dimensional.

Let space of a representation of the group G be the boundary space $C(L)$. For the case of compact group we have decompositions

$$C(L) = \sum_{k=0}^{\infty} \oplus \tilde{C}^k, \qquad C(\ker L) = \sum_{k=0}^{\infty} \oplus C^k(\ker L), \qquad B = \sum_{k=0}^{\infty} \oplus B^k.$$

If our G-invariant boundary value problem is well-posed, the decompositions in the direct sum $C(L) = C(\ker L) \oplus B$ imply decompositions in the direct sum $C^k := C^k(\ker L) \oplus B^k = \sum\limits_l \tilde{C}^{k_l}$ with finite-dimensional projectors Π^k: $C^k \to C^k(\ker L)$ along B^k and now check of the well-posedness of a G-invariant boundary value problem can be reduced to check of two properties:

1) $C^k(\ker L) \cap B^k = 0$;

2) $\exists\ \kappa > 0, \quad \forall\ k, \quad \|\Pi^k\|_{C^k} < \kappa.$

Below we shall study a spectrum of an operator of a general well-posed equivariant boundary value problem for the Poisson equation in a disk and in a ball, detecting cases of violation of the well-posedness of the problem, which are expressed in violation of property 1). Thus the fulfilment of property 2) will be assured by the assumed property of the well-posedness of this problem for the Poisson equation.

2 Equivariant boundary value problems for the Helmholtz equation in a disk

Let us conduct evaluations on check of two properties of the well-posedness of a general equivariant boundary value problem in a simplest case. As the group we will choose group of rotations of the plane $SO(2, \mathbb{R})$. It is compact commutative group.

Let us consider the problem (1), where $\mathcal{L} = \Delta$ and L is the maximum operator generated by the Laplace operator Δ, invariant with respect to the action of rotations group, domain $\Omega = K = \{x \in \mathbb{R}^2 \,|\, |x| < 1\}$ is the disk. Let us remark, that here we have $L = \tilde{L}$, i.e. each function from $D(L)$ can be approximated by smooth functions. Let us assume that this boundary value problem is G-invariant and is well-posed.

And we study such boundary value problem for the Helmholtz equation

$$L_\lambda v = \Delta v + \lambda^2 v = g, \qquad \Gamma v \in B,$$

where λ is a complex number. But in the beginning we study the boundary space $C(L_\lambda)$ of the Helmholtz operator and its subspace $C(\ker L_\lambda)$.

Boundary space consists of some pairs of functions $(u|_{\partial\Omega}, u'_\nu|_{\partial\Omega}) \in H^{-1/2}(\partial K) \times H^{-3/2}(\partial K)$, therefore a general boundary condition must have the form

$$Au|_{\partial K} + Bu'_\nu|_{\partial K} = 0$$

with some operators A, B. The G-invariance of this condition means the commutativity of operators A and B with all the representation operators. But, as it is well-known, a rotation invariant linear operator has a form of the convolution with a function. Therefore we will consider boundary value problems of the type:

$$\alpha * u|_{\partial K} - \beta * u'_\nu|_{\partial K} = 0,$$

where $\alpha = \sum \alpha_k e^{ik\tau}$; $\beta = \sum \beta_k e^{ik\tau}$ are functions on the boundary ∂K, $*$ is the convolution on ∂K: $\alpha * \psi = \sum \alpha_k \psi_k e^{ik\tau}$.

The boundary condition for Fourier coefficients of functions $u|_{\partial\Omega}$, $u'_\nu|_{\partial\Omega}$ from the space B can be written in the form

$$\forall\, k \in \mathbb{Z}, \qquad \alpha_k a_k + \beta_k b_k = 0. \tag{2}$$

Let us designate by C^k an image of an enclosure I_k: $\mathbb{C}^2 \to C(L)$ acting by a rule I_k: $(a,b) \to (ae^{ik\tau}, be^{ik\tau})$. The boundary problem sets a subspace B of the space $C(L)$, which, as we see, intersects each space C^k in a straight line. The well-posedness of our problem, i.e. expansion in the direct sum $C(L_\lambda) = B \oplus C(\ker L_\lambda)$, means now that

$$\exists\, A > 0, \quad \forall\, k \in \mathbb{Z}, \quad |\sin(B^k, C^k(\ker L_\lambda))| > A,$$

i.e.

$$\forall\, k, \quad \frac{|\beta_k \lambda J'_k(\lambda) - \alpha_k J_k(\lambda)|}{\sqrt{|\lambda J'_k(\lambda)|^2 + |J_k(\lambda)|^2}} > A > C \quad \text{at} \quad \lambda \neq 0$$

and

$$\frac{|k\beta_k - \alpha_k|}{\sqrt{k^2+1}} > A > 0 \quad \text{at} \quad \lambda = 0.$$

Proposition 1. *The problem* (2)*, which is well-posed for the equation* $\Delta u = g$*, is well-posed for the equation* $\Delta u + \lambda^2 u = g$ *at* $\lambda \neq 0$ *if and only if the following condition holds*

$$\forall\, k, \quad |k\beta_k J^1_k(\lambda) - \alpha_k J^2_k(\lambda)| \neq 0.$$

Proposition 2. *Spectrum of the operator of well-posed boundary value problem* (2) *for the equation* $\Delta u = g$ *is a set* $\bigcup\limits_k \Sigma_k$*, where* Σ_k *is the set of proper values of a form* $-\lambda^2$ *and* λ *runs all zeros of the equation*

$$\beta_k \lambda J'_k(\lambda) - \alpha_k J_k(\lambda) = 0 \quad \textit{at} \quad \lambda \neq 0. \tag{3}$$

Proposition 3. *Spectrum of the operator of well-posed boundary value problem* (2) *for the equation* $\Delta u = g$ *is finite-to-one.*

Proposition 4. *Every well-posed* G*-invariant boundary value problem for the Poisson equation is quite correct, i.e. its solving operator is compact.*

Propositions concerning the same equation on n-dimensional ball have similar formulations but the equation (3) has the following form:

$$\beta^1_l \lambda J'_{\nu+l}(\lambda) - \beta^1_l \nu J_{\nu+l}(\lambda) - \alpha^1_l J_{\nu+l}(\lambda) = 0,$$

where $\nu = \frac{n}{2} - 1$, $l \in \mathbb{N} \cup 0$.

And the corresponding equivariant boundary value problem must have the following form:

$$u|_{\partial\Omega} * \alpha + u'_\nu|_{\partial\Omega} * \beta = 0,$$

where $\alpha = \sum\limits_{l=0}^{\infty} \sum\limits_k \alpha^k_l H^k_l$, $\beta = \sum\limits_{l=0}^{\infty} \sum\limits_k \beta^k_l H^k_l$ are functions on sphere S^{n-1}, which are decomposed in Fourier series, $*$ is convolution on $\partial\Omega$: $\psi * \alpha = \sum\limits_{l=0}^{\infty} \sum\limits_k \psi^k_l \alpha^1_l H^k_l$, what means, in particular, that we can omit tesseral (not zonal) parts in decomposition α and β.

On the Deformations of Dorfman's and Sokolov's Operators

Jen-Hsu CHANG

Department of General Courses, Chung-Cheng Institute of Technology, National Defense University, Tau-Yuan County, Taiwan
E-mail: *jhchang@ccit.edu.tw*

We deform the Dorfman's and Sokolov's Hamiltonian operators by the quasi-Miura transformation coming from the topological field theory and investigate the deformed operators.

1 Introduction

The Dorfman's and Sokolov's Hamiltonian operators are defined respectively as [2,11] ($D = \partial_x$)

$$J = D\frac{1}{v_x}D\frac{1}{v_x}D, \tag{1}$$

$$S = v_x D^{-1} v_x, \tag{2}$$

which are Hamiltonian operators (or $J^{-1} = D^{-1}v_x D^{-1} v_x D^{-1}$ and $S^{-1} = \frac{1}{v_x}D\frac{1}{v_x}$ are symplectic operators). The Dorfman's operator J (or J^{-1}) and the Sokolov's operator S are related to integrable equations as follows.

- The Riemann hierarchy

$$v_{t_n} = v^n v_x = S\delta H_n = \frac{1}{(n+1)(2n+1)}K\delta H_{n+1} = \frac{1}{(n+1)(n+2)}D\delta H_{n+2}$$
$$= \frac{1}{(n+1)(n+2)(n+3)(n+4)}J\delta H_{n+4}, \tag{3}$$

where

$$K = Dv + vD, \qquad H_n = \int v^n dx, \qquad n = 1, 2, 3\ldots,$$

and δ is the variational derivative. When $n = 1$, it is called the Riemann equation or dispersionless KdV equation. We notice that it seems that the Riemann hierarchy (3) is a quater-Hamiltonian system. But one can show that S and J is not compatible, i.e., $S + \lambda J$ are not a Hamiltonian operator for any $\lambda \neq 0$ (see below).

- The Schwarzian KdV equation [10,13]

$$v_t = v_{xxx} - \frac{3}{2}\frac{v_{xx}^2}{v_x} = v_x\{v, x\} = S\delta H_1 = J^{-1}\delta H_2, \tag{4}$$

where $\{v, x\}$ is the Schwartz derivative and

$$H_1 = \frac{1}{2}\int \left(v_x^{-2}v_{xx}^2\right) dx, \qquad H_2 = \frac{1}{2}\int \left(-v_x^{-2}v_{xxx}^2 + \frac{3}{4}v_x^{-4}v_{xx}^4\right) dx.$$

Remark 1. It is not difficult to verify that J^{-1} is also a Hamiltonian operator and, then, J is also a symplectic operator; however, $S^{-1} = \frac{1}{v_x}D\frac{1}{v_x}$ is <u>not</u> a Hamiltonian operator and, then, S is not a symplectic operator.

Next, to deform the operators J and S, we use the free energy in topological field theory of the famous KdV equation

$$u_t = uu_x + \frac{\epsilon^2}{12}u_{xxx} \tag{5}$$

to construct the quasi-Miura transformation as follows. The free energy F of KdV equation (5) in TFT has the form ($F_0 = \frac{1}{6}v^3$)

$$F = \frac{1}{6}v^3 + \sum_{g=1}^{\infty} \epsilon^{2g-2} F_g \left(v; v_x, v_{xx}, v_{xxx}, \ldots, v^{(3g-2)} \right).$$

Let

$$\begin{aligned} \triangle F &= \sum_{g=1}^{\infty} \epsilon^{2g-2} F_g \left(v; v_x, v_{xx}, v_{xxx}, \ldots, v^{(3g-2)} \right) \\ &= F_1(v; v_x) + \epsilon^2 F_2(v; v_x, v_{xx}, v_{xxx}, v_{xxxx}) \\ &\quad + \epsilon^4 F_3 \left(v; v_x, v_{xx}, v_{xxx}, v_{xxxx}, \ldots, v^{(7)} \right) + \cdots . \end{aligned}$$

The $\triangle F$ will satisfy the loop equation [4, p. 151]

$$\begin{aligned} &\sum_{r\geq 0} \frac{\partial \triangle F}{\partial v^{(r)}} \partial_x^r \frac{1}{v-\lambda} + \sum_{r\geq 1} \frac{\partial \triangle F}{\partial v^{(r)}} \sum_{k=1}^{r} \left(\begin{array}{c} r \\ k \end{array} \right) \partial_x^{k-1} \frac{1}{\sqrt{v-\lambda}} \partial_x^{r-k+1} \frac{1}{\sqrt{v-\lambda}} \\ &\quad = \frac{1}{16\lambda^2} - \frac{1}{16(v-\lambda)^2} - \frac{\kappa_0}{\lambda^2} \\ &\quad + \frac{\epsilon^2}{2} \sum_{k,l\geq 0} \left[\frac{\partial^2 \triangle F}{\partial v^{(k)} \partial v^{(l)}} + \frac{\partial \triangle F}{\partial v^{(k)}} \frac{\partial \triangle F}{\partial v^{(l)}} \right] \partial_x^{k+1} \frac{1}{\sqrt{v-\lambda}} \partial_x^{l+1} \frac{1}{\sqrt{v-\lambda}} \\ &\quad - \frac{\epsilon^2}{16} \sum_{k\geq 0} \frac{\partial \triangle F}{\partial v^{(k)}} \partial_x^{k+2} \frac{1}{(v-\lambda)^2}. \end{aligned} \tag{6}$$

Then we can determine F_1, F_2, F_3, ... recursively by substituting $\triangle F$ into equation (6). For F_1, one obtains

$$\frac{1}{v-\lambda}\frac{\partial F_1}{\partial v} - \frac{3}{2}\frac{v_x}{(v-\lambda)^2}\frac{\partial F_1}{\partial v_x} = \frac{1}{16\lambda^2} - \frac{1}{16(v-\lambda)^2} - \frac{\kappa_0}{\lambda^2}.$$

From this, we have

$$\kappa_0 = \frac{1}{16}, \qquad F_1 = \frac{1}{24}\log v_x.$$

For the next terms $F_2(v; v_x, v_{xx}, v_{xxx}, v_{xxxx})$, it can be similarly computed and the result is

$$F_2 = \frac{v_{xxxx}}{1152 v_x^2} - \frac{7 v_{xx} v_{xxx}}{1920 v_x^3} + \frac{v_{xx}^3}{360 v_x^4}.$$

Now, one can define the quasi-Miura transformation as

$$\begin{aligned} u &= v + \epsilon^2 (\triangle F)_{xx} = v + \epsilon^2 (F_1)_{xx} + \epsilon^4 (F_2)_{xx} + \cdots \\ &= v + \frac{\epsilon^2}{24}(\log v_x)_{xx} + \epsilon^4 \left(\frac{v_{xxxx}}{1152 v_x^2} - \frac{7 v_{xx} v_{xxx}}{1920 v_x^3} + \frac{v_{xx}^3}{360 v_x^4} \right)_{xx} + \cdots . \end{aligned} \tag{7}$$

One remarks that Miura-type transformation means the coefficients of ϵ are homogeneous polynomials in the derivatives $v_x, v_{xx}, \ldots, v^{(m)}$ [4, p. 37], [5] and "quasi" means the ones of ϵ are quasi-homogeneous rational functions in the derivatives, too [4, p. 109] (see also [12]).

The truncated quasi-Miura transformation

$$u = v + \sum_{n=1}^{g} \epsilon^{2n} \left[F_n \left(v; v_x, v_{xx}, \ldots, v^{(3g-2)} \right) \right]_{xx} \tag{8}$$

has the basic property [4, p. 117] that it reduces the Magri–Poisson pencil [6] of KdV equation (5)

$$\{u(x), u(y)\}_\lambda = [u(x) - \lambda] D\delta(x-y) + \frac{1}{2} u_x(x)\delta(x-y) + \frac{\epsilon^2}{8} D^3\delta(x-y) \tag{9}$$

to the Poisson pencil of the Riemann hierarchy (3):

$$\{v(x), v(y)\}_\lambda = [v(x) - \lambda] D\delta(x-y) + \frac{1}{2} v_x(x)\delta(x-y) + O\left(\epsilon^{2g+2}\right). \tag{10}$$

One can also say that the truncated quasi-Miura transformation (8) deforms the KdV equation (5) to the Riemann equation $v_t = vv_x$ up to $O\big(\epsilon^{2g+2}\big)$.

Remark 2. A simple calculation shows that, under the transformation $u = \frac{\epsilon^2}{4}\{m, x\}$, the KdV equation (5) is transformed into the Schwarzian KdV equation

$$m_t = \frac{\epsilon^2}{12} m_x \{m, x\} = \frac{\epsilon^2}{12} \left(m_{xxx} - \frac{3}{2} \frac{m_{xx}^2}{m_x} \right).$$

Furthermore, after a direct calculation, one can see that the Magri Poisson bracket

$$K(\epsilon) = \{u(x), u(y)\} = u(x) D\delta(x-y) + \frac{1}{2} u_x(x)\delta(x-y) + \frac{\epsilon^2}{8} D^3\delta(x-y) \tag{11}$$

is transformed into the Dorfman's symplectic operator J^{-1} $(m = v)$

$$\{m(x), m(y)\} = -\frac{\epsilon^2}{8} D^{-1} m_x D^{-1} m_x D^{-1} \delta(x-y).$$

Now, a natural question arises: under the truncated quasi-Miura transformation (8), are the deformed Dorfman's operator $J(\epsilon)$ and Sokolov's operator $S(\epsilon)$ still Hamiltonian operators up to $O\big(\epsilon^{2g+2}\big)$? For simplicity, we consider only the case $g = 1$, i.e.,

$$u = v + \frac{\epsilon^2}{24} (\log v_x)_{xx} + O\left(\epsilon^4\right) \tag{12}$$

or

$$v = u - \frac{\epsilon^2}{24} (\log u_x)_{xx} + O\left(\epsilon^4\right). \tag{13}$$

The answer is true for the Dorfman's operator $J(\epsilon)$ but it is false for the Sokolov's operator $S(\epsilon)$. It is the purpose of this article.

2 Deformations under quasi-Miura transformation

In the new "u-coordinate", J and S will be given by the operators

$$J(\epsilon) = M^* D \frac{1}{u_x - \frac{\epsilon^2}{24}(\log u_x)_{xxx}} D \frac{1}{u_x - \frac{\epsilon^2}{24}(\log u_x)_{xxx}} DM + O\left(\epsilon^4\right), \tag{14}$$

$$S(\epsilon) = M^* \left(u_x - \frac{\epsilon^2}{24}(\log u_x)_{xxx}\right) D^{-1} \left(u_x - \frac{\epsilon^2}{24}(\log u_x)_{xxx}\right) M + O\left(\epsilon^4\right), \tag{15}$$

where

$$M = 1 - \frac{\epsilon^2}{24} D \frac{1}{u_x} D^2, \qquad M^* = 1 + \frac{\epsilon^2}{24} D^2 \frac{1}{u_x} D, \tag{16}$$

M^* being the adjoint operator of M. Then we have the following

Theorem 1. 1. *$J(\epsilon)$ is a Hamiltonian operator up to $O\left(\epsilon^4\right)$.* 2. *$S(\epsilon)$ is <u>not</u> a Hamiltonian operator up to $O\left(\epsilon^4\right)$.*

Proof. 1. The fact that $J(\epsilon)$ is a skew-adjoint (or $J^*(\epsilon) = -J(\epsilon)$) differential operator (up to $O\left(\epsilon^4\right)$) follows immediately from (14). Rather than prove the Poisson form [7] of the Jacobi identity for $J(\epsilon)$, it is simpler to prove that the symplectic two-form

$$\Omega_J(\epsilon) = \int \{du \wedge J(\epsilon)^{-1} du\} dx + O\left(\epsilon^4\right)$$

is closed [8,9]: $d\Omega_J(\epsilon) = O\left(\epsilon^4\right)$.

A simple calculation can yield

$$\begin{aligned}
J(\epsilon)^{-1} &= \left(1 + \frac{\epsilon^2}{24} D \frac{1}{u_x} D^2\right) D^{-1} \left(u_x - \frac{\epsilon^2}{24}(\log u_x)_{xxx}\right) D^{-1} \\
&\quad \times \left(u_x - \frac{\epsilon^2}{24}(\log u_x)_{xxx}\right) D^{-1} \left(1 - \frac{\epsilon^2}{24} D^2 \frac{1}{u_x} D\right) \\
&= \left(D^{-1} u_x - \frac{\epsilon^2}{24} D^{-1}(\log u_x)_{xxx} + \frac{\epsilon^2}{24} D \frac{1}{u_x} D u_x\right) D^{-1} \\
&\quad \times \left(u_x D^{-1} - \frac{\epsilon^2}{24}(\log u_x)_{xxx} D^{-1} - \frac{\epsilon^2}{24} u_x D \frac{1}{u_x} D\right) + O\left(\epsilon^4\right) \\
&= D^{-1} u_x D^{-1} u_x D^{-1} + \frac{\epsilon^2}{24} \left[D \frac{1}{u_x} D u_x D^{-1} u_x D^{-1} - D^{-1}(\log u_x)_{xxx} D^{-1} u_x D^{-1}\right. \\
&\quad \left. - D^{-1} u_x D^{-1} u_x D \frac{1}{u_x} D - D^{-1} u_x D^{-1}(\log u_x)_{xxx} D^{-1}\right] + O\left(\epsilon^4\right) \\
&= D^{-1} u_x D^{-1} u_x D^{-1} \\
&\quad + \frac{\epsilon^2}{24} \left[D u_x D^{-1} - D^{-1} u_x D + (\log u_x)_x u_x D^{-1} + D^{-1}(\log u_x)_x u_x\right] + O\left(\epsilon^4\right).
\end{aligned}$$

Let ψ denote the potential function for u, i.e., $u = \psi_x$. Thus, formally,

$$D_x^{-1}(du) = d\psi$$

and hence, after a series of integration by parts, one has

$$\begin{aligned}
\Omega_J(\epsilon) = \int \left\{ \left[\left(D^{-1} d\left(\frac{\psi_x^2}{2}\right)\right) \wedge d\left(\frac{\psi_x^2}{2}\right) - \psi_x d\psi \wedge d\left(\frac{\psi_x^2}{2}\right)\right] \right. \\
\left. + \frac{\epsilon^2}{24} \left[2\psi_{xx} d\psi \wedge d\psi_{xx} + 2\psi_{xxx} d\psi_x \wedge d\psi\right] \right\} dx + O\left(\epsilon^4\right).
\end{aligned}$$

So

$$d\Omega_J(\epsilon) = \int \left\{ 0 + \frac{\epsilon^2}{12} \left[d\psi_{xxx} \wedge d\psi_x \wedge d\psi \right] \right\} dx + O\left(\epsilon^4\right)$$
$$= \frac{\epsilon^2}{12} \int \left\{ (d\psi_{xx} \wedge d\psi_x \wedge d\psi)_x \right\} dx + O(\epsilon^4) = O\left(\epsilon^4\right).$$

This completes the proof of (1).

2. The skew-adjoint property of the deformed Sokolov's operator $S(\epsilon)$ (15) is obvious. To see whether $S(\epsilon)$ is Hamiltonian operator or not, we must check whether $S(\epsilon)$ satisfies the Jacobi identity up to $O\left(\epsilon^4\right)$. Following [7, 8], we introduce the arbitrary basis of tangent vector Θ, which is then conveniently manipulated according to the rules of exterior calculus. The Jacobi identity is given by the compact expression

$$P(\epsilon) \wedge \delta I = O\left(\epsilon^4\right) \quad \text{(mod. div.)}, \tag{17}$$

where $P(\epsilon) = S(\epsilon)\Theta$, $I = \frac{1}{2}\Theta \wedge P(\epsilon)$ and δ denotes the variational derivative. The vanishing of the tri-vector (17) modulo a divergence is equivalent to the satisfaction of the Jacobi identity.

After a tedious calculation, one can obtain

$$S(\epsilon) = M^* \left(u_x - \frac{\epsilon^2}{24} (\log u_x)_{xxx} \right) D^{-1} \left(u_x - \frac{\epsilon^2}{24} (\log u_x)_{xxx} \right) M + O\left(\epsilon^4\right)$$
$$= \left[u_x + \frac{\epsilon^2}{24} \left(D^3 + D^2 (\log u_x)_x - (\log u_x)_{xxx} \right) \right] D^{-1}$$
$$\times \left[u_x - \frac{\epsilon^2}{24} \left(D^3 - (\log u_x)_x D^2 + (\log u_x)_{xxx} \right) \right] + O\left(\epsilon^4\right)$$
$$= u_x D^{-1} u_x + \frac{\epsilon^2}{24} \left[D^2 u_x + D^2 (\log u_x)_x D^{-1} u_x - (\log u_x)_{xxx} D^{-1} u_x - u_x D^2 \right.$$
$$\left. + u_x D^{-1} (\log u_x)_x D^2 - u_x D^{-1} (\log u_x)_{xxx} \right] + O\left(\epsilon^4\right)$$
$$= u_x D^{-1} u_x + \frac{\epsilon^2}{24} \left[D^2 u_x - u_x D^2 + (\log u_x)_x D u_x + u_x D (\log u_x)_x \right] + O\left(\epsilon^4\right)$$
$$= u_x D^{-1} u_x + \frac{\epsilon^2}{12} [D u_{xx} + u_{xx} D] + O\left(\epsilon^4\right).$$

So

$$P(\epsilon) = S(\epsilon)\Theta = u_x D^{-1} (u_x \Theta) + \frac{\epsilon^2}{12} [2 u_{xx} \Theta_x + u_{xxx} \Theta] + O\left(\epsilon^4\right).$$

Hence

$$I = \frac{1}{2} \Theta \wedge P(\epsilon) = \frac{1}{2} u_x \Theta \wedge D^{-1} (u_x \Theta) + \frac{\epsilon^2}{12} u_{xx} \Theta \wedge \Theta_x + O\left(\epsilon^4\right)$$

and then

$$\delta I = -\frac{1}{2} [\Theta \wedge D^{-1} (u_x \Theta)]_x - \frac{1}{2} u_x \Theta \wedge D^{-1} (\Theta_x) + \frac{\epsilon^2}{12} [\Theta \wedge \Theta_x]_{xx} + O\left(\epsilon^4\right)$$
$$= -\frac{1}{2} \Theta_x \wedge D^{-1} (u_x \Theta) + \frac{\epsilon^2}{12} [\Theta \wedge \Theta_x]_{xx} + O\left(\epsilon^4\right).$$

Finally,

$$\begin{aligned}
P(\epsilon)\wedge\delta I &= \left\{u_xD^{-1}(u_x\Theta)+\frac{\epsilon^2}{12}[2u_{xx}\Theta_x+u_{xxx}\Theta]\right\}\\
&\quad\wedge\left\{-\frac{1}{2}\Theta_x\wedge D^{-1}(u_x\Theta)+\frac{\epsilon^2}{12}[\Theta\wedge\Theta_x]_{xx}\right\}+O\left(\epsilon^4\right)\\
&= 0+\frac{\epsilon^2}{12}\Big\{-\frac{1}{2}u_{xxx}\Theta\wedge\Theta_x\wedge D^{-1}(u_x\Theta)+u_{xxx}D^{-1}(u_x\Theta)\wedge\Theta\wedge\Theta_x\\
&\quad+3u_{xx}u_x\Theta\wedge\Theta\wedge\Theta_x+u_x^2\Theta_x\wedge\Theta\wedge\Theta_x\Big\}+O\left(\epsilon^4\right)\\
&= 0+\frac{\epsilon^2}{24}u_{xxx}\Theta\wedge\Theta_x\wedge D^{-1}(u_x\Theta),
\end{aligned}$$

which can be easily checked that it cannot be expressed as a total divergence. So $S(\epsilon)$ cannot satisfy the Jacobi identity and therefore $S(\epsilon)$ is not a Hamiltonian operator. This completes the proof of (2). ■

Remark 3. Using the technics of the last proof, one can show that J and S is <u>not</u> compatible. Since J and S are Hamiltonian operators, what we are going to do is show that [7, 8]

$$\tilde{Q}(\Theta)\wedge\delta R+Q(\Theta)\wedge\delta\tilde{R}\neq 0\quad(\text{mod.}\quad\text{div.}),$$

where

$$\begin{aligned}
&Q(\Theta)=v_xD^{-1}(v_x\Theta),\qquad R=\frac{1}{2}\Theta\wedge Q(\Theta),\\
&\tilde{Q}(\Theta)=\left(\frac{1}{v_x}\left(\frac{\Theta_x}{v_x}\right)_x\right)_x,\qquad \tilde{R}=\frac{1}{2}\Theta\wedge\tilde{Q}(\Theta)=-\frac{1}{2v_x^2}\Theta_x\wedge\Theta_{xx}.
\end{aligned}$$

Then

$$\delta R=\frac{-1}{2}[\Theta\wedge D^{-1}(v_x\Theta)]_x-\frac{1}{2}v_x\Theta\wedge D^{-1}(\Theta_x)=\frac{-1}{2}\Theta_x\wedge D^{-1}(v_x\Theta)$$

and

$$\delta\tilde{R}=-\left(\frac{1}{v_x^3}\Theta_x\wedge\Theta_{xx}\right)_x.$$

Hence

$$\begin{aligned}
&\tilde{Q}(\Theta)\wedge\delta R+Q(\Theta)\wedge\delta\tilde{R}\\
&\quad=\left(\frac{1}{v_x}\left(\frac{\Theta_x}{v_x}\right)_x\right)_x\wedge\left(\frac{-1}{2}\Theta_x\wedge D^{-1}(v_x\Theta)\right)-v_xD^{-1}(v_x\Theta)\wedge\left(\frac{1}{v_x^3}\Theta_x\wedge\Theta_{xx}\right)_x\\
&\quad=\frac{1}{2}\frac{1}{v_x}\left(\frac{\Theta_x}{v_x}\right)_x\wedge\left[\Theta_{xx}\wedge D^{-1}(v_x\Theta)+v_x\Theta_x\wedge\Theta\right]\\
&\qquad+\left[v_{xx}D^{-1}(v_x\Theta)+v_x^2\Theta\right]\wedge\left(\frac{1}{v_x^3}\Theta_x\wedge\Theta_{xx}\right)\\
&\quad=\frac{1}{2v_x}\Theta_{xx}\wedge\Theta_x\wedge\Theta-\frac{v_{xx}}{2v_x^3}\Theta_x\wedge\Theta_{xx}\wedge D^{-1}(v_x\Theta)\\
&\qquad+\frac{v_{xx}}{v_x^3}D^{-1}(v_x\Theta)\wedge\Theta_x\wedge\Theta_{xx}+\frac{1}{v_x}\Theta\wedge\Theta_x\wedge\Theta_{xx}\\
&\quad=\frac{1}{2v_x}\Theta\wedge\Theta_x\wedge\Theta_{xx}+\frac{v_{xx}}{2v_x^3}\Theta_x\wedge\Theta_{xx}\wedge D^{-1}(v_x\Theta)\\
&\quad\neq 0\quad(\text{mod. div.}),
\end{aligned}$$

as required.

3 Concluding remarks

• That $J(\epsilon)$ is a Hamiltonian operator (up to $O(\epsilon^4)$) is proved in [1]. We give another proof here, which remarkably simplifies the proof given in [1].
• We notice that all the deformed operators $J(\epsilon)$ (14), $D(\epsilon)$ $\left(= D + O\left(\epsilon^4\right)\right)$, $K(\epsilon)$ (11) under the quasi-Miura transformation (7) are Hamiltonian operators (up to $O\left(\epsilon^4\right)$). That the deformed Sokolov's operator $S(\epsilon)$ is not Hamiltonian is a little surprising that means that the Poisson bracket of the Hamiltonians $H_m(u;\epsilon)$, $H_n(u;\epsilon)$ for $S(\epsilon)$

$$\{H_m(u;\epsilon), H_n(u;\epsilon)\}_{S(\epsilon)}$$

will not be $O\left(\epsilon^4\right)$ but $O\left(\epsilon^2\right)$, i.e., it cannot be a conserved quantity of the Riemann hierarchy (3).

Non-Lie Reductions of Nonlinear Reaction-Diffusion Systems with Variable Diffusivities

Roman CHERNIHA

Institute of Mathematics of NAS of Ukraine, 3 Tereshchenkivs'ka Str., 01601 Kyiv, Ukraine
E-mail: *cherniha@imath.kiev.ua*

Non-Lie reductions to systems of first-order ordinary differential equations are performed for a class of systems of two quasilinear reaction-diffusion equations having variable diffusivities. Moreover, families of exact solutions of a diffusive Lotka–Volterra type system are constructed.

1 Introduction

In this communication, semilinear systems of two reaction-diffusion (RD) equations of the form

$$\begin{aligned} U_t &= d_1(U^{\alpha_1}U_x)_x + U(a_1 + b_1U^{\alpha_1}) + U^{1-\alpha_1}(h_1 + c_1V^{\alpha_2}),\\ V_t &= d_2(V^{\alpha_2}V_x)_x + V(a_2 + b_2V^{\alpha_2}) + V^{1-\alpha_2}(h_2 + c_2U^{\alpha_1}) \end{aligned} \tag{1}$$

are considered. Here the subscripts t and x to the functions U and V denote differentiation with respect to these variables and all the coefficients are constants. The communication is organized as follows. In Section 2, a set of new non-Lie ansätze are constructed which reduce RD system (1) to systems of four or more ordinary differential equations. It is shown that these ansätze cannot be obtained using Lie symmetries of this system. In Section 3, families of exact solutions of the RD system

$$\begin{aligned} U_t &= (UU_x)_x + U(a_1 + b_1U) + h_1 + c_1V,\\ V_t &= (VV_x)_x + V(a_2 + b_2V) + h_2 + c_2U. \end{aligned} \tag{2}$$

One can note that system (2) is a system of Lotka–Volterra type, with variable (degenerate) diffusivities (see, e.g. [1]), in which the standard terms c_1UV and c_2UV are replaced by the terms $h_1 + c_1V$ and $h_2 + c_2U$, respectively. Hereafter this RD system will be referred as the degenerate diffusive Lotka–Volterra system (DDLV system).

2 New non-Lie ansätze for the RD system (1)

This section is devoted to non-Lie reductions of RD systems with power-law nonlinearities of the form (1). Hereafter I assume that *both* equations contain diffusion coefficients with variable diffusivities and that the system is coupled, i.e., $d_1d_2\alpha_1\alpha_2 \neq 0$, and $c_1 \neq 0$ or $c_2 \neq 0$.

It is easily checked that the linear substitution

$$U = d_1^{-1/\alpha_1}U^*, \qquad V = d_2^{-1/\alpha_2}V^* \tag{3}$$

reduces (1) to the same form with $d_1 = d_2 = 1$; therefore, without losing generality, I can consider DDLV systems of the form

$$\begin{aligned} U_t &= (U^{\alpha_1}U_x)_x + U(a_1 + b_1U^{\alpha_1}) + U^{1-\alpha_1}(h_1 + c_1V^{\alpha_2}),\\ V_t &= (V^{\alpha_2}V_x)_x + V(a_2 + b_2V^{\alpha_2}) + V^{1-\alpha_2}(h_2 + c_2U^{\alpha_1}). \end{aligned} \tag{4}$$

According to the results of group classification for systems of two reaction-diffusion equations with variable diffusivities [2,3], system (4) is invariant only with respect to the trivial Lie algebra with the basic operators

$$P_t = \partial_t, \qquad P_x = \partial_x \tag{5}$$

if the coefficients are arbitrary constants. However, there are the following special cases leading to non-trivial algebras of invariance: $b_1 = b_2 = h_1 = h_2 = 0$ (see case 6 of Table 1 in [3]); $b_1 = b_2 = h_1 = h_2 = 0$ and $\alpha_1 = \alpha_2 = -4/3$ (see case 9 of Table 1 in [3]); $b_1 = b_2 \neq 0$, $h_1 = h_2 = 0$ and $\alpha_1 = \alpha_2 = -4/3$ (see cases 10 and 12 of Table 1 in [3]). In particular, the DDLV system (4) admits only the trivial Lie algebra (5) if $h_1 \neq 0$ or $h_2 \neq 0$.

With $U = u^{1/\alpha_1}$, $V = v^{1/\alpha_2}$ this system is reduced to the form

$$\begin{aligned} u_t &= uu_{xx} + \frac{1}{\alpha_1}u_x^2 + \alpha_1\left[h_1 + a_1u + b_1u^2 + c_1v\right], \\ v_t &= vv_{xx} + \frac{1}{\alpha_2}v_x^2 + \alpha_2\left[h_2 + a_2v + b_2v^2 + c_2u\right], \end{aligned} \tag{6}$$

where $u(t,x)$ and $v(t,x)$ are new unknown functions. One observes that system (6) contains only quadratic nonlinearities. Several new approaches were recently suggested to find exact solutions of single evolution equation with quadratic nonlinearities (see [6–10] and references cited therein). Those approaches lead to so called non-Lie ansätze which cannot be found using the classical Lie method and the non-classical Bluman–Cole method [11] (it was, however, shown in [12] that some solutions constructed by those ansätze can be found by a modification of the Bluman–Cole method).

However, it is not easy to apply those approaches for finding exact solutions of systems of equations. To my knowledge there are only a few papers devoted to the case of evolution systems [13, 10, 14].

It turns out that it is possible to construct non-Lie ansätze and to interpret the relevant exact solutions of the system (6) using the notion of additional generating conditions [10, 15].

Consider an additional generating condition of the following non-coupled system of third order ordinary differential equations (ODEs)

$$\beta_1(t)\frac{du}{dx} + \beta_2(t)\frac{d^2u}{dx^2} + \frac{d^3u}{dx^3} = 0, \qquad \beta_1(t)\frac{dv}{dx} + \beta_2(t)\frac{d^2v}{dx^2} + \frac{d^3v}{dx^3} = 0, \tag{7}$$

where $\beta_1(t)$ and $\beta_2(t)$ are arbitrary smooth functions and the variable t is considered as a parameter. Depending on the coefficients, the solution to the linear ODE system (7) can take the following forms:

$$u = \varphi_0(t) + \varphi_1(t)x + \varphi_2(t)x^2, \qquad v = \psi_0(t) + \psi_1(t)x + \psi_2(t)x^2 \tag{8}$$

if $\beta_1 = \beta_2 = 0$;

$$u = \varphi_0(t) + \varphi_1(t)x + \varphi_2(t)\exp(\gamma(t)x), \qquad v = \psi_0(t) + \psi_1(t)x + \psi_2(t)\exp(\gamma(t)x) \tag{9}$$

if $\beta_1 = 0$;

$$\begin{aligned} u &= \varphi_0(t) + \varphi_1(t)\exp(\gamma_1(t)x) + \varphi_2(t)\exp(\gamma_2(t)x), \\ v &= \psi_0(t) + \psi_1(t)\exp(\gamma_1(t)x) + \psi_2(t)\exp(\gamma_2(t)x) \end{aligned} \tag{10}$$

if $\gamma_{1,2}(t) = \frac{1}{2}\left(\pm\sqrt{D} - \beta_2\right)$, $D = \beta_2^2 - 4\beta_1 > 0$ and $\gamma_1 \neq \gamma_2$;

$$u = \varphi_0(t) + \exp\left(-\frac{\beta_2 x}{2}\right)\left[\varphi_1(t)\cos\left(\frac{\sqrt{-D}}{2}x\right) + \varphi_2(t)\sin\left(\frac{\sqrt{-D}}{2}x\right)\right],$$

$$v=\psi_0(t)+\exp\left(-\frac{\beta_2 x}{2}\right)\left[\psi_1(t)\cos\left(\frac{\sqrt{-D}}{2}x\right)+\psi_2(t)\sin\left(\frac{\sqrt{-D}}{2}x\right)\right] \tag{11}$$

if $D<0$; and, finally,

$$\begin{aligned} u&=\varphi_0(t)+\varphi_1(t)\exp(\gamma(t)x)+x\varphi_2(t)\exp(\gamma(t)x),\\ v&=\psi_0(t)+\psi_1(t)\exp(\gamma(t)x)+x\psi_2(t)\exp(\gamma(t)x) \end{aligned} \tag{12}$$

if $D=0$, i.e. $\gamma_1=\gamma_2=\gamma\neq 0$.

Let me consider relations (8)–(12) as a chain of ansätze for the system (6). It is important to note that each ansatz contains 6 yet-to-be determined functions φ_i, ψ_i, $i=0,1,2$. This enables us to reduce the given system of PDEs to a nonlinear system of first-order ODEs for the unknown functions φ_i and ψ_i (γ, β_1 and β_2 can provide additional unknowns, depending on the ansatz in question). Indeed, calculating the derivatives U_t, U_x, U_{xx} with the help of ansatz (8) and substituting them into system (6), one obtains an expression, which can be splitted into separate parts for the powers of x. Simultaneously the restriction on coefficients

$$b_1=b_2=0 \tag{13}$$

is required (otherwise $\varphi_1=\psi_1=\varphi_2=\psi_2=0$) and then a correctly-specified ODE system for the functions φ_i and ψ_i has the form

$$\begin{aligned} \dot{\varphi_0}&=2\varphi_0\varphi_2+\frac{1}{\alpha_1}\varphi_1^2+\alpha_1(h_1+a_1\varphi_0+c_1\psi_0),\\ \dot{\psi_0}&=2\psi_0\psi_2+\frac{1}{\alpha_2}\psi_1^2+\alpha_2(h_2+a_2\psi_0+c_2\varphi_0),\\ \dot{\varphi_1}&=\frac{2\alpha_1+4}{\alpha_1}\varphi_1\varphi_2+\alpha_1(a_1\varphi_1+c_1\psi_1),\\ \dot{\psi_1}&=\frac{2\alpha_2+4}{\alpha_2}\psi_1\psi_2+\alpha_2(a_2\psi_1+c_2\varphi_1),\\ \dot{\varphi_2}&=\frac{2\alpha_1+4}{\alpha_1}\varphi_2^2+\alpha_1(a_1\varphi_2+c_1\psi_2),\\ \dot{\psi_2}&=\frac{2\alpha_2+4}{\alpha_2}\psi_2^2+\alpha_2(a_2\psi_2+c_2\varphi_2). \end{aligned} \tag{14}$$

Finally, given any solution of the ODE system (14), one constructs an exact solution of DDLV system (4), (13) of the form

$$U=\left(\varphi_0+\varphi_1 x+\varphi_2 x^2\right)^{1/\alpha_1},\qquad V=\left(\psi_0+\psi_1 x+\psi_2 x^2\right)^{1/\alpha_2}. \tag{15}$$

In the case of ansatz (9), two different subcases are obtained, namely: (i) $\alpha_1\neq -1$ and $\alpha_2\neq -1$; (ii) $\alpha_1=\alpha_2=-1$.

The first subcase leads to the requirement $\varphi_1=\psi_1=0$ and then the ansatz reduces to a particular case of the ansatz (10) that will be considered below. Consider the second subcase. In a similar way to the above calculation for the ansatz (8), I arrive at the coefficient restrictions (13) and also $a_1+c_1=a_2+c_2$, together with the following correctly-specified ODE system for the functions γ, φ_i and ψ_i

$$\begin{aligned} &\dot{\gamma}=\varphi_1\gamma^2,\qquad \psi_1=\varphi_1,\qquad \dot{\varphi_1}=-(a_1+c_1)\varphi_1,\\ &\dot{\varphi_0}=-\left(h_1+a_1\varphi_0+c_1\psi_0+\varphi_1^2\right),\\ &\dot{\psi_0}=-\left(h_2+a_2\psi_0+c_2\varphi_0+\psi_1^2\right),\\ &\dot{\varphi_2}=\gamma^2\varphi_0\varphi_2-2\gamma\varphi_1\varphi_2-(a_1\varphi_2+c_1\psi_2), \end{aligned}$$

$$\dot{\psi_2} = \gamma^2\psi_0\psi_2 - 2\gamma\psi_1\psi_2 - (a_2\psi_2 + c_2\varphi_2). \tag{16}$$

Thus, any solution of (16) generates an exact solution of the form

$$U = (\varphi_0 + \varphi_1 x + \varphi_2 \exp\gamma x)^{-1}, \qquad V = (\psi_0 + \psi_1 x + \psi_2 \exp\gamma x)^{-1} \tag{17}$$

of the DDLV system

$$\begin{aligned} U_t &= \left(U^{-1}U_x\right)_x + U(a_1 + h_1U + c_1\,U/V), \\ V_t &= \left(V^{-1}V_x\right)_x + V(a_2 + h_2V + c_2\,V/U), \end{aligned} \tag{18}$$

where $a_1 + c_1 = a_2 + c_2$.

Analogously, the ansätze (10) and (11) have been analysed and the two different subcases listed above were found too. Considering the subcase (i), I have obtained the restriction on coefficients

$$\gamma_1 = -\gamma_2 = \sqrt{-\frac{b_1\alpha_1^2}{\alpha_1+1}} = \sqrt{-\frac{b_2\alpha_2^2}{\alpha_2+1}} \equiv \gamma \tag{19}$$

for both ansätze. To find real solutions ansatz (10) can be applied only for $\frac{b_k}{\alpha_k+1} < 0$, $k = 1, 2$ while ansatz (11) works only for $\frac{b_k}{\alpha_k+1} > 0$, $k = 1, 2$. The relevant ODE systems for finding the functions φ_i and ψ_i have the form

$$\begin{aligned} \dot{\varphi_0} &= \alpha_1 b_1\varphi_0^2 + \alpha_1(h_1 + a_1\varphi_0 + c_1\psi_0) - \frac{4}{\alpha_1}\gamma^2\varphi_1\varphi_2, \\ \dot{\psi_0} &= \alpha_2 b_2\psi_0^2 + \alpha_2(h_2 + a_2\psi_0 + c_2\varphi_0) - \frac{4}{\alpha_2}\gamma^2\psi_1\psi_2, \\ \dot{\varphi_1} &= (2\alpha_1 b_1 + \gamma^2)\varphi_0\varphi_1 + \alpha_1(a_1\varphi_1 + c_1\psi_1), \\ \dot{\psi_1} &= (2\alpha_2 b_2 + \gamma^2)\psi_0\psi_1 + \alpha_2(a_2\psi_1 + c_2\varphi_1), \\ \dot{\varphi_2} &= (2\alpha_1 b_1 + \gamma^2)\varphi_0\varphi_2 + \alpha_1(a_1\varphi_2 + c_1\psi_2), \\ \dot{\psi_2} &= (2\alpha_2 b_2 + \gamma^2)\psi_0\psi_2 + \alpha_2(a_2\psi_2 + c_2\varphi_2) \end{aligned} \tag{20}$$

and

$$\begin{aligned} \dot{\varphi_0} &= \alpha_1 b_1\varphi_0^2 + \alpha_1(h_1 + a_1\varphi_0 + c_1\psi_0) - \frac{\gamma^2}{\alpha_1}\left(\varphi_1^2 + \varphi_2^2\right), \\ \dot{\psi_0} &= \alpha_2 b_2\psi_0^2 + \alpha_2(h_2 + a_2\psi_0 + c_2\varphi_0) - \frac{\gamma^2}{\alpha_2}\left(\psi_1^2 + \psi_2^2\right), \\ \dot{\varphi_1} &= (2b_1\alpha_1 + \gamma^2)\varphi_0\varphi_1 + \alpha_1(a_1\varphi_1 + c_1\psi_1), \\ \dot{\psi_1} &= (2b_2\alpha_2 + \gamma^2)\psi_0\psi_1 + \alpha_2(a_2\psi_1 + c_2\varphi_1), \\ \dot{\varphi_2} &= (2b_1\alpha_1 + \gamma^2)\varphi_0\varphi_2 + \alpha_1(a_1\varphi_2 + c_1\psi_2), \\ \dot{\psi_2} &= (2b_2\alpha_2 + \gamma^2)\psi_0\psi_2 + \alpha_2(a_2\psi_2 + c_2\varphi_2) \end{aligned} \tag{21}$$

respectively. The resulting exact solutions of the DDLV system (4) take the form

$$\begin{aligned} U &= \left[\varphi_0(t) + \varphi_1(t)\exp(-\gamma x) + \varphi_2(t)\exp(\gamma x)\right]^{1/\alpha_1}, \\ V &= \left[\psi_0(t) + \psi_1(t)\exp(-\gamma x) + \psi_2(t)\exp(\gamma x)\right]^{1/\alpha_2} \end{aligned} \tag{22}$$

and

$$U = \left[\varphi_0(t) + \varphi_1(t)\cos(|\gamma|x) + \varphi_2(t)\sin(|\gamma|x)\right]^{1/\alpha_1},$$

$$V = \left[\psi_0(t) + \psi_1(t)\cos(|\gamma|x) + \psi_2(t)\sin(|\gamma|x)\right]^{1/\alpha_2}. \tag{23}$$

In the subcase (ii), the restrictions

$$\gamma_1 = -\gamma_2 = \gamma \in \mathbb{R}, \qquad b_1 = b_2 = 0 \tag{24}$$

arise instead of (19). The corresponding systems of ODEs coincide with (20) and (21), in which one needs to set $b_k = 0$, $\alpha_k = -1$, $k = 1, 2$.

Finally, I have established that ansatz (12) can be applied only in the case $\varphi_2 = \psi_2 = 0$, i.e. if one is reduced to a particular case of (10).

I have also investigated the direct generalization of (8) of the form

$$u = \varphi_0 + \varphi_1 x + \cdots + \varphi_{m_1} x^{m_1}, \qquad v = \psi_0 + \psi_1 x + \cdots + \psi_{m_2} x^{m_2}. \tag{25}$$

It can be shown that ansatz (25) reduces system (6) to a correctly-specified ODE system only in the cases $m_1 = m_2 = 3$ and $m_1 = m_2 = 4$ (otherwise $\varphi_i = \psi_i = 0$, $i > 2$). The corresponding restrictions on the coefficients are as follows: $\alpha_1 = \alpha_2 = -\frac{3}{2}$, $b_1 = b_2 = 0$ for $m_1 = m_2 = 3$ and $\alpha_1 = \alpha_2 = -\frac{4}{3}$, $b_1 = b_2 = 0$ for $m_1 = m_2 = 4$. The relevant ODE systems are omitted here but one can find them in [4].

It should be noted that both exponents of power nonlinearities $\alpha = -\frac{3}{2}$ and $\alpha = -\frac{4}{3}$ were earlier found (see [16, 17] and [9]) to provide reductions of the single RD equation

$$U_t = (U^\alpha U_x)_x + a_1 U + c_1 U^{1-\alpha}. \tag{26}$$

3 Exact solutions of the DDLV system (2)

Consider system (2) and assume $b_1 b_2 \neq 0$ and $c_1 c_2 \neq 0$, i.e. the system contains quadratic nonlinearities in the reaction terms and the equations are coupled. Taking into account [2, 3], one easily observes that under these typical restrictions on coefficients, the DDLV system (2) is invariant only with respect to the trivial algebra (5). So, one can find in that manner only plane wave solutions of the form

$$U = \varphi(\omega), \qquad V = \psi(\omega), \qquad \omega = k_1 x - k_0 t, \tag{27}$$

where $k_0, k_1 \in \mathbb{R}$ and the functions φ and ψ are solutions of the reduced ODE system

$$\begin{aligned} &k_1^2(\varphi\varphi_\omega)_\omega + k_0\varphi_\omega + \varphi(a_1 + b_1\varphi) + h_1 + c_1\psi = 0,\\ &k_1^2(\psi\psi_\omega)_\omega + k_0\psi_\omega + \psi(a_2 + b_2\psi) + h_2 + c_2\varphi = 0. \end{aligned} \tag{28}$$

The ODE system (28) is not integrable for $k_1 \neq 0$, and only particular solutions can be find (some of them are presented below). The case $k_1 = 0$ of course leads to solutions which do not depend on the space variable.

It turns out that a much wider class of exact solutions of the DDLV system (2) can be constructed using the non-Lie reductions presented in Section 3. Consider the ODE system (20) with $\alpha_1 = \alpha_2 = 1$. As it was shown above, this system is obtained from system (2) using the ansatz

$$\begin{aligned} &U = \varphi_0(t) + \varphi_1(t)\exp(-\gamma x) + \varphi_2(t)\exp(\gamma x),\\ &V = \psi_0(t) + \psi_1(t)\exp(-\gamma x) + \psi_2(t)\exp(\gamma x), \end{aligned} \tag{29}$$

where $\gamma = \sqrt{\frac{b}{2}}$, $b = -b_1 = -b_2 > 0$.

It can be noted that the ODE system (20) admits essential simplification for $\varphi_2 = \psi_2 = 0$, reducing to

$$\dot{\varphi}_0 = -b\varphi_0^2 + h_1 + a_1\varphi_0 + c_1\psi_0, \qquad \dot{\psi}_0 = -b\psi_0^2 + h_2 + a_2\psi_0 + c_2\varphi_0,$$
$$\dot{\varphi}_1 = -\frac{3}{2}b\varphi_0\varphi_1 + a_1\varphi_1 + c_1\psi_1, \qquad \dot{\psi}_1 = -\frac{3}{2}b\psi_0\psi_1 + a_2\psi_1 + c_2\varphi_1. \tag{30}$$

Now one observes that the first two equations of (30) decouple. Formally speaking, this subsystem has four steady-state solutions. I assume that there is at least one real solution among them, say (U_0, V_0). In other words, (U_0, V_0) is a real solution of the system of algebraic equations

$$bU_0^2 = h_1 + a_1U_0 + c_1V_0, \qquad bV_0^2 = h_2 + a_2V_0 + c_2U_0. \tag{31}$$

Substituting $\varphi_0 = U_0$, $\psi_0 = V_0$ into the last two equation of (30), one arrives at a linear ODE system

$$\dot{\varphi}_1 = \left(a_1 - \frac{3}{2}bU_0\right)\varphi_1 + c_1\psi_1, \qquad \dot{\psi}_1 = c_2\varphi_1 + \left(a_2 - \frac{3}{2}bV_0\right)\psi_1. \tag{32}$$

According to the classical theory of linear ODE systems, the form of the general solution of (32) depends on $\triangle_1 = [(a_1 - a_2) + \frac{3}{2}b(V_0 - U_0)]^2 + 4c_1c_2$. So I obtain the following general solutions of (32):

if $\triangle_1 > 0$ then

$$\varphi_1 = e_1c_1\exp(s_1t) + e_2\left(s_2 - a_2 + \frac{3}{2}bV_0\right)\exp(s_2t),$$
$$\psi_1 = e_1\left(s_1 - a_1 + \frac{3}{2}bU_0\right)\exp(s_1t) + e_2c_2\exp(s_2t), \tag{33}$$

where $s_{1,2} = \frac{1}{2}\left[a_1 + a_2 - \frac{3}{2}b(U_0 + V_0) \pm \sqrt{\triangle_1}\right]$;

if $\triangle_1 < 0$ then

$$\varphi_1 = c_1\exp(pt)(e_1\sin(qt) + e_2\cos(qt)),$$
$$\psi_1 = \exp(pt)\left[\left(e_1\left(p - a_1 + \frac{3}{2}bU_0\right) - e_2q\right)\sin(qt) + \left(e_1q + e_2\left(p - a_1 + \frac{3}{2}bU_0\right)\right)\cos(qt)\right], \tag{34}$$

where $p = \frac{1}{2}\Big(a_1 + a_2 - \frac{3}{2}b(U_0 + V_0)\Big)$, $q = \frac{1}{2}\sqrt{-\triangle_1}$;

if $\triangle_1 = 0$ then

$$\varphi_1 = (e_1c_1t + c_2)\exp(st),$$
$$\psi_1 = \left[e_1(1 \pm \sqrt{-c_1c_2}t) \pm e_2\sqrt{\frac{-c_2}{c_1}}\right]\exp(st)m, \tag{35}$$

where $s = \frac{1}{2}\left[a_1 + a_2 - \frac{3}{2}b(U_0 + V_0)\right]$. Here e_1 and e_2 are arbitrary constants.

Thus, three two-parameter families of exact solutions of the DDLV system

$$U_t = (UU_x)_x + U(a_1 - bU) + h_1 + c_1V,$$
$$V_t = (VV_x)_x + V(a_2 - bV) + h_2 + c_2U \tag{36}$$

of the form

$$U = U_0 + \varphi_1(t)\exp\left(-\sqrt{\frac{b}{2}}x\right), \qquad V = V_0 + \psi_1(t)\exp\left(-\sqrt{\frac{b}{2}}x\right) \tag{37}$$

can be constructed. Of course, each family arises only if the coefficients of the DDLV system (36) satisfy the relevant conditions on $\triangle_1$.

It should be stressed that any exact solution (37) with $\varphi_1(t)$ and $\psi_1(t)$ given by (33)–(35) is a non-Lie solution of the DDLV system (36) if $e_1e_2 \neq 0$. In fact, it is easily seen that this solution cannot be reduced to the form (27), i.e. it cannot be obtained using the Lie symmetries of the DDLV system (36). However, one observes that all solutions obtained, except the solution generated by formulas (37) and (34), are reduced to the form (27) if $e_1 = 0$. In other words, these two-parameter families of solutions contain as subclasses one-parameter families of Lie solutions.

Some other families of exact solutions of DDLV (2) are constructed in [4].

Acknowledgements

Finally, I am grateful to Prof. John King for the fruitful discussion on solutions of system (2) and to Dr. Alexander Zhalij for the reference [2].

Bogoyavlenskij Symmetries of Isotropic and Anisotropic MHD Equilibria as Lie Point Transformations

Alexei F. CHEVIAKOV

Department of Mathematics, Queen's University, Kingston, Ontario K7L 3N6, Canada
E-mail: *alexch@mast.queensu.ca*

Isotropic Magnetohydrodynamic (MHD) Equilibrium Equations and generalized Anisotropic Magnetohydrodynamic (Chew–Goldberger–Low, CGL) Equilibrium Equations possess infinite-dimensional groups of intrinsic symmetries. We show that certain non-trivial Lie point transformations (that can be obtained by direct application of the general Lie group analysis method) are equivalent to Bogoyavlenskij symmetries in both isotropic and anisotropic cases.

1 Introduction

Among all descriptions of plasma as a continuous medium, two single-fluid models are used most frequently. They are the isotropic magnetohydrodynamics (MHD) equations [1] and the anisotropic CGL (Chew–Goldberger–Low) magnetohydrodynamics equations [2]. Both of them are generalizations of Navier–Stokes system onto the case of conducting fluids; they are derived from Boltzmann and Maxwell equations under different isotropy assumptions.

The isotropic MHD approximation employs scalar pressure p and is valid when the mean free path of plasma particles is much smaller than the typical scale of the problem, so that the picture is maintained nearly isotropic via frequent collisions.

On the other hand, when the mean free path for particle collisions is long compared to Larmor radius, for instance, in strongly magnetized or rarified plasmas, the CGL approximation should be used. In this model, the pressure is a tensor with two different components: the pressure along the magnetic field $p_{\|}$ and in the transverse direction $p_{\perp}$. In the limit $p_{\perp} = p_{\|} = p$, CGL and MHD models coincide.

The applications of these models include but are not limited to the problem of controlled thermonuclear fusion, astrophysical applications (star formation, solar activity, astrophysical jets) and terrestrial applications (laboratory and industrial plasmas, ball lightning models). The relevant references are [1, 3–9].

Similarly to the Navier–Stokes gas dynamics equations, both MHD and CGL models are essentially nonlinear, and there are no methods so far for solving corresponding general initial/boundary value problems. There also is a lack of physically relevant particular analytical solutions that could model specific phenomena.

In recent papers [10, 11] Bogoyavlenskij introduced new symmetry transforms of the ideal MHD equilibrium equations. In certain classes of plasma configurations, Bogoyavlenskij symmetries break geometrical symmetry, thus giving rise to important classes of non-symmetric MHD equilibrium solutions.

In [12], we have shown that anisotropic CGL plasma equilibria possess similar topology-dependent infinite-dimensional symmetries, which generalize Bogoyavlenskij symmetries.

It is shown that Bogoyavlenskij symmetries for isotropic plasmas and generalized Bogoyavlenskij symmetries for anisotropic plasmas are equivalent to in particular Lie groups of point transformations, which are found independently using the classical Lie group analysis method.

The Lie symmetry method [13] used in this work finds Lie groups of point symmetries of partial differential equations. Lie transformations are used to build particular solutions of the system under consideration, to reduce the order and to obtain invariants. Self-similar solutions constructed from Lie symmetries often have direct physical significance. Many appropriate examples can be found in [14].

We remark, however, that not all symmetries of a given system can be found by the Lie method, but only continuous symmetries that have one-parametric Lie group structure.

In Section 2 of this paper, the isotropic and anisotropic plasma equilibrium equations are described, together with their most important properties, including their Bogoyavlenskij symmetries.

In Sections 3 and 4, the general Lie point symmetry method is described, and an equivalence correspondence is established between Bogoyavlenskij symmetries for isotropic and anisotropic plasmas and certain infinite-dimensional Lie point symmetry groups.

2 MHD and CGL equilibrium equations

The equilibrium states of isotropic moving plasmas are described by the system of MHD equilibrium equations, which under the assumptions of infinite conductivity and negligible viscosity has the form [1]

$$\rho \boldsymbol{V} \times \operatorname{curl} \boldsymbol{V} - \frac{1}{\mu} \boldsymbol{B} \times \operatorname{curl} \boldsymbol{B} - \operatorname{grad} P - \rho \operatorname{grad} \frac{\boldsymbol{V}^2}{2} = 0, \tag{1}$$

$$\operatorname{div} \rho \boldsymbol{V} = 0, \qquad \operatorname{curl} (\boldsymbol{V} \times \boldsymbol{B}) = 0, \qquad \operatorname{div} \boldsymbol{B} = 0. \tag{2}$$

Here $\boldsymbol{V}$ is plasma velocity; $\boldsymbol{B}$ is the vector of the magnetic field induction; ρ, plasma density; P, plasma pressure; and μ, magnetic permeability coefficient.

In the case of incompressible plasma, the equation

$$\operatorname{div} \boldsymbol{V} = 0 \tag{3}$$

is added to the above system. In this paper we restrict our consideration to incompressible plasmas.

It is known [10, 11, 15, 16] that all compact incompressible MHD equilibrium configurations, except the Beltrami case $\operatorname{curl} \boldsymbol{B} = \alpha \boldsymbol{B}$, $\alpha = \text{const}$, have two-dimensional magnetic surfaces – the vector fields $\boldsymbol{B}$ and $\boldsymbol{V}$ are in every point tangent to magnetic surfaces. The magnetic surfaces may not exist for unbounded incompressible MHD equilibrium configurations with $\boldsymbol{V} \parallel \boldsymbol{B}$.

In the case when plasma Larmor radius is small compared to characteristic dimensions of the system, the set of equations was found by Chew, Goldberger and Low [2]. The anisotropic equilibrium equations are:

$$\rho \boldsymbol{V} \times \operatorname{curl} \boldsymbol{V} - \frac{1}{\mu} \boldsymbol{B} \times \operatorname{curl} \boldsymbol{B} = \operatorname{div} \mathbb{P} + \rho \operatorname{grad} \frac{\boldsymbol{V}^2}{2}, \tag{4}$$

$$\operatorname{div} \rho \boldsymbol{V} = 0, \qquad \operatorname{curl} (\boldsymbol{V} \times \boldsymbol{B}) = 0, \qquad \operatorname{div} \boldsymbol{B} = 0, \tag{5}$$

where $\mathbb{P}$ is the pressure tensor with two independent components:

$$\mathbb{P} = \mathbb{I} p_\perp + \frac{p_\parallel - p_\perp}{\boldsymbol{B}^2} (\boldsymbol{B}\boldsymbol{B}). \tag{6}$$

Here $\mathbb{I}$ is a unit tensor.

For this system to be closed, one needs to add to it two equations of state. In this paper we will consider incompressible CGL plasmas: $\operatorname{div} \boldsymbol{V} = 0$.

Using vector calculus identities, the pressure tensor divergence may be rewritten in the form

$$\operatorname{div}\mathbb{P} = \operatorname{grad} p_\perp + \tau \operatorname{curl}\boldsymbol{B}\times\boldsymbol{B} + \tau \operatorname{grad}\frac{\boldsymbol{B}^2}{2} + \boldsymbol{B}(\boldsymbol{B}\cdot\operatorname{grad}\tau), \tag{7}$$

$$\tau = \frac{p_\parallel - p_\perp}{\boldsymbol{B}^2}. \tag{8}$$

Hence the system (4), (5) rewrites as

$$\rho\boldsymbol{V}\times\operatorname{curl}\boldsymbol{V} - \left(\frac{1}{\mu} - \tau\right)\boldsymbol{B}\times\operatorname{curl}\boldsymbol{B} = \operatorname{grad} p_\perp + \rho\operatorname{grad}\frac{\boldsymbol{V}^2}{2} + \tau\operatorname{grad}\frac{\boldsymbol{B}^2}{2} + \boldsymbol{B}(\boldsymbol{B}\cdot\operatorname{grad}\tau), \tag{9}$$

$$\operatorname{div}\boldsymbol{V} = 0, \qquad \operatorname{div}\boldsymbol{B} = 0, \qquad \operatorname{curl}(\boldsymbol{V}\times\boldsymbol{B}) = 0. \tag{10}$$

Recently Bogoyavlenskij [10, 11] found that the ideal MHD equilibrium equations (1)–(3) possess the following symmetries.

Let $\{\boldsymbol{V}(\boldsymbol{r}), \boldsymbol{B}(\boldsymbol{r}), P(\boldsymbol{r}), \rho(\boldsymbol{r})\}$ be a solution of (1)–(3), where the density $\rho(\boldsymbol{r})$ is constant on both magnetic field lines and streamlines. Then $\{\boldsymbol{V}_1(\boldsymbol{r}), \boldsymbol{B}_1(\boldsymbol{r}), P_1(\boldsymbol{r}), \rho_1(\boldsymbol{r})\}$ is also a solution, where

$$\boldsymbol{V}_1 = \frac{b(\boldsymbol{r})}{m(\boldsymbol{r})\sqrt{\mu\rho}}\boldsymbol{B} + \frac{a(\boldsymbol{r})}{m(\boldsymbol{r})}\boldsymbol{V}, \qquad \boldsymbol{B}_1 = a(\boldsymbol{r})\boldsymbol{B} + b(\boldsymbol{r})\sqrt{\mu\rho}\,\boldsymbol{V}, \tag{11}$$

$$\rho_1 = m^2(\boldsymbol{r})\rho, \qquad P_1 = CP + \left(C\boldsymbol{B}^2 - \boldsymbol{B}_1^2\right)/(2\mu).$$

Here

$$a^2(\boldsymbol{r}) - b^2(\boldsymbol{r}) = C = \text{const},$$

and $a(\boldsymbol{r})$, $b(\boldsymbol{r})$, $c(\boldsymbol{r})$ are functions constant on both magnetic field lines and streamlines (i.e. on magnetic surfaces $\Psi = \text{const}$, when they exist).

These transformations form an infinite-dimensional Abelian group [11]

$$G_m = A_m \oplus A_m \oplus R^+ \oplus Z_2 \oplus Z_2 \oplus Z_2, \tag{12}$$

where R^+ is a multiplicative group of positive numbers, and A_m is an additive Abelian group of smooth functions in $\mathbb{R}^3$ that are constant on magnetic surfaces. The group G_m has eight connected components.

In [12] we have found that a similar group of transformations is present in the case of anisotropic (CGL) incompressible plasma equilibria: let $\{\boldsymbol{V}(\boldsymbol{r}), \boldsymbol{B}(\boldsymbol{r}), p_\perp(\boldsymbol{r}), p_\parallel(\boldsymbol{r}), \rho(\boldsymbol{r})\}$ be a solution of the CGL system (9), (10), where the density $\rho(\boldsymbol{r})$ and the anisotropy factor $\tau(\boldsymbol{r})$ (8) are constant on both magnetic field lines and streamlines. Then $\{\boldsymbol{V_1}(\boldsymbol{r}), \boldsymbol{B_1}(\boldsymbol{r}), p_{\perp 1}(\boldsymbol{r}), p_{\parallel 1}(\boldsymbol{r}), \rho_1(\boldsymbol{r})\}$ is also a solution, where

$$\rho_1 = m^2(\boldsymbol{r})\rho,$$

$$\boldsymbol{V}_1 = \frac{b(\boldsymbol{r})\sqrt{1/\mu - \tau}}{m(\boldsymbol{r})\sqrt{\rho}}\boldsymbol{B} + \frac{a(\boldsymbol{r})}{m(\boldsymbol{r})}\boldsymbol{V}, \qquad \boldsymbol{B}_1 = \frac{a(\boldsymbol{r})}{n(\boldsymbol{r})}\boldsymbol{B} + \frac{b(\boldsymbol{r})\sqrt{\rho}}{n(\boldsymbol{r})\sqrt{1/\mu - \tau}}\boldsymbol{V},$$

$$p_{\perp 1} = Cp_\perp + \frac{(C\boldsymbol{B}^2 - \boldsymbol{B}_1^2)}{2\mu},$$

$$p_{\parallel 1} = p_\parallel n^2(\boldsymbol{r})\frac{\boldsymbol{B}_1^2}{\boldsymbol{B}^2} + p_\perp\left(C - n^2(\boldsymbol{r})\frac{\boldsymbol{B}_1^2}{\boldsymbol{B}^2}\right) + \frac{(C\boldsymbol{B}^2 + \boldsymbol{B}_1{}^2(1 - 2n^2(\boldsymbol{r})))}{2\mu}. \tag{13}$$

Here

$$a^2(\boldsymbol{r}) - b^2(\boldsymbol{r}) = C = \text{const},$$

and $a(\boldsymbol{r})$, $b(\boldsymbol{r})$, $m(\boldsymbol{r})$, $n(\boldsymbol{r})$ are functions constant on both magnetic field lines and streamlines.

For these symmetries, the anisotropy factor $\tau(\boldsymbol{r})$ is transformed as follows:

$$\tau_1 \equiv \frac{p_{\parallel 1} - p_{\perp 1}}{\boldsymbol{B_1}^2} = \frac{1}{\mu} - n^2(\boldsymbol{r}) \left(\frac{1}{\mu} - \tau \right). \tag{14}$$

The transformations for anisotropic case form an Abelian Lie group $G = A_m \oplus A_m \oplus A_m \oplus R^+ \oplus Z_2 \oplus Z_2 \oplus Z_2 \oplus Z_2$ with sixteen connected components.

3 Lie group formalism for the MHD equilibrium equations

A solution to a system of l first-order partial differential equations

$$\begin{aligned}
&\boldsymbol{E}(\boldsymbol{x}, \boldsymbol{u}, \underset{1}{\boldsymbol{u}}) = 0, \\
&\boldsymbol{E} = (E^1, \ldots, E^l), \qquad \boldsymbol{x} = (x^1, \ldots, x^n) \in X, \qquad \boldsymbol{u} = (u^1, \ldots, u^m) \in U, \\
&\underset{1}{\boldsymbol{u}} = \left(\frac{\partial u^j}{\partial x^i} \middle| \, i = 1, \ldots, n; \; j = 1, \ldots, m \right) \in U_1
\end{aligned} \tag{15}$$

represents a manifold Ω in $(m+n)$-dimensional space $X \times U$, which corresponds to a manifold Ω^1 in $(m + n + mn)$-dimensional prolonged (jet) space $X \times U \times U_1$ of dependent and independent variables together with partial derivatives [13].

Studying ideal MHD equilibria, one should take into account the generally the plasma domain is spanned by nested 2-dimensional *magnetic surfaces* – surfaces on which magnetic field lines and plasma streamlines lie [16].

The Lie method of seeking one-parametric groups of transformations that map solutions of (15) into solutions consists in finding the Lie algebra of vector fields tangent to the solution manifold Ω^1 in the jet space. These vector fields serve as infinitesimal generators for a Lie symmetry group with representation

$$\begin{aligned}
&(x')^i = f^i(\boldsymbol{x}, \boldsymbol{u}, a) \qquad (i = 1, \ldots, n), \\
&(u')^j = g^j(\boldsymbol{x}, \boldsymbol{u}, a) \qquad (j = 1, \ldots, m),
\end{aligned} \tag{16}$$

and have the form

$$\boldsymbol{v} = \sum_i \xi^i(\boldsymbol{x}, \boldsymbol{u}) \frac{\partial}{\partial x^i} + \sum_k \eta^k(\boldsymbol{x}, \boldsymbol{u}) \frac{\partial}{\partial u^k} + \sum_{i,\,k} \xi_i^k(\boldsymbol{x}, \boldsymbol{u}, \underset{1}{\boldsymbol{u}}) \frac{\partial}{\partial u_i^k}. \tag{17}$$

Components of these tangent vector fields are expressed through the group representation as follows:

$$\begin{aligned}
&\xi^i(\boldsymbol{x}, \boldsymbol{u}) = \frac{\partial f^i(\boldsymbol{x}, \boldsymbol{u}, a)}{\partial a}\Big|_{a=0}, \qquad \eta^j(\boldsymbol{x}, \boldsymbol{u}) = \frac{\partial g^j(\boldsymbol{x}, \boldsymbol{u}, a)}{\partial a}\Big|_{a=0}, \\
&i = 1, \ldots, n, \qquad j = 1, \ldots, m.
\end{aligned} \tag{18}$$

The variables ξ_i^k in (17) are the coordinates of the prolonged tangent vector field corresponding to the derivatives u_i^k:

$$\xi_i^j(\boldsymbol{x}, \boldsymbol{u}, \underset{1}{\boldsymbol{u}}) = D_i \eta^j - \sum_{k=1}^{n} u_k^j D_i \xi^k, \qquad D_i \equiv \frac{\partial}{\partial x^i} + \sum_{j=1}^{m} u_i^j \frac{\partial}{\partial u^j}. \tag{19}$$

The relation (19) defines an isomorphism between tangent vector fields (17) and infinitesimal operators

$$X = \sum_i \xi^i(\boldsymbol{x}, \boldsymbol{u}) \frac{\partial}{\partial x^i} + \sum_k \eta^k(\boldsymbol{x}, \boldsymbol{u}) \frac{\partial}{\partial u^k}. \tag{20}$$

The explicit reconstruction of the transformations (16) from a generator (17) is done by solving the initial value problem

$$\begin{aligned} &\frac{\partial f^i(a)}{\partial a} = \xi^i(\boldsymbol{f}, \boldsymbol{g}), && \frac{\partial g^k(a)}{\partial a} = \eta^k(\boldsymbol{f}, \boldsymbol{g}), \\ &f^i(0) = x^i, && g^k(0) = u^k. \end{aligned} \tag{21}$$

To find all Lie group generators admissible by the original system (15), one needs to solve the determining equations

$$\boldsymbol{v}\boldsymbol{E}(\boldsymbol{x}, \boldsymbol{u}, \underset{1}{\boldsymbol{u}})\Big|_{\boldsymbol{E}(\boldsymbol{x}, \boldsymbol{u}, \underset{1}{\boldsymbol{u}})=0} = 0. \tag{22}$$

All l determining equations (22) are linear partial differential equations with respect to $m+n$ unknown functions (18) of $m+n$ variables.

4 Connection between Bogoyavlenskij symmetries and Lie transformations

In this section the equivalence is established between Bogoyavlenskij symmetries (11), (13) for isotropic and anisotropic cases and certain infinite-dimensional Lie group transformations.

Theorem 1 shows that the application of the Lie group formalism to MHD equilibria (1), (2) yields certain Lie point transformations, some of which depend on arbitrary functions.

Theorem 2 proves that these Lie point transformations are equivalent to the groups G_m of Bogoyavlenskij symmetries (11).

Theorems 3 and 4 contain similar statements for Anisotropic (CGL) plasma equilibria.

Theorem 1. *Consider the incompressible MHD equilibrium system of equations* (1)–(3)*, where the density $\rho(\boldsymbol{r})$ is constant on both magnetic field lines and streamlines. This system admits the infinitesimal operators*

$$X^{(1)} = M(\boldsymbol{r}) \left(\sum_{k=1}^{3} \frac{B_k}{\mu\rho} \frac{\partial}{\partial V_k} + \sum_{k=1}^{3} V_k \frac{\partial}{\partial B_k} - \frac{1}{\mu} (\boldsymbol{V} \cdot \boldsymbol{B}) \frac{\partial}{\partial P} \right), \tag{23}$$

$$X^{(2)} = \sum_{k=1}^{3} V_k \frac{\partial}{\partial V_k} + \sum_{k=1}^{3} B_k \frac{\partial}{\partial B_k} + 2P \frac{\partial}{\partial P}, \tag{24}$$

$$X^{(3)} = N(\boldsymbol{r}) \left(2\rho \frac{\partial}{\partial \rho} - \sum_{k=1}^{3} V_k \frac{\partial}{\partial V_k} \right), \tag{25}$$

$$X^{(4)} = \frac{\partial}{\partial P}. \tag{26}$$

These operators form a basis of the Lie algebra of infinitesimal operators in the class of Lie point transformations $\{\boldsymbol{x}' = \boldsymbol{x},\ \boldsymbol{u}' = \boldsymbol{g}(\boldsymbol{u}, a)\}$. Here $M(\boldsymbol{r})$, $N(\boldsymbol{r})$ are arbitrary smooth functions constant on both magnetic field lines and streamlines.

The proof of Theorem 1 is given in [17]. All infinitesimal operators are obtained by direct differentiation of Bogoyavlenskij symmetries with respect to a properly chosen parameter.

Remark 1. Let us explicitly write down the transformations contained in the infinitesimal operators (23)–(26). According to the reconstruction procedure (21), for the operator (23), we have

$$\rho_1 = \rho, \qquad \boldsymbol{x}_1 = \boldsymbol{x},$$

and solve the linear initial value problem

$$\begin{aligned} &\frac{\partial \boldsymbol{V}_1}{\partial \tau} = \boldsymbol{B}_1 \frac{M(\boldsymbol{r})}{\mu\rho}, \qquad \frac{\partial \boldsymbol{B}_1}{\partial \tau} = \boldsymbol{V}_1 M(\boldsymbol{r}), \qquad \frac{\partial P_1}{\partial \tau} = -\frac{M(\boldsymbol{r})}{\mu}(\boldsymbol{V}_1 \cdot \boldsymbol{B}_1), \\ &\boldsymbol{V}_1(\tau = 0) = \boldsymbol{V}, \qquad \boldsymbol{B}_1(\tau = 0) = \boldsymbol{B}, \qquad P_1(\tau = 0) = P. \end{aligned} \tag{27}$$

The solution is

$$\begin{aligned} &\boldsymbol{B}_1 = \cosh\left(\frac{M(\boldsymbol{r})\tau}{\sqrt{\mu\rho}}\right)\boldsymbol{B} + \sinh\left(\frac{M(\boldsymbol{r})\tau}{\sqrt{\mu\rho}}\right)\sqrt{\mu\rho}\,\boldsymbol{V}, \\ &\boldsymbol{V}_1 = \sinh\left(\frac{M(\boldsymbol{r})\tau}{\sqrt{\mu\rho}}\right)\frac{\boldsymbol{B}}{\sqrt{\mu\rho}} + \cosh\left(\frac{M(\boldsymbol{r})\tau}{\sqrt{\mu\rho}}\right)\boldsymbol{V}, \\ &P_1 = P + (\boldsymbol{B}^2 - \boldsymbol{B}_1^2)/(2\mu), \qquad \rho_1 = \rho. \end{aligned} \tag{28}$$

The infinitesimal operator (23) thus contains the possibility of "mixing" the components of the vector fields $\boldsymbol{B}$ and $\boldsymbol{V}$ of the original solution into a new solution.

The same way by solving a corresponding initial value problem (21) we find that transformations contained in the operator (24) are scalings

$$\rho_1 = \rho, \qquad \boldsymbol{B}_1 = \exp(\tau)\boldsymbol{B}, \qquad \boldsymbol{V}_1 = \exp(\tau)\boldsymbol{V}, \qquad P_1 = \exp(2\tau)P; \tag{29}$$

the operator (25) corresponds to infinite-dimensional scalings

$$\rho_1 = \exp(2N(\boldsymbol{r})\tau)\rho, \qquad \boldsymbol{B}_1 = \boldsymbol{B}, \qquad \boldsymbol{V}_1 = \exp(-N(\boldsymbol{r})\tau)\boldsymbol{V}, \qquad P_1 = P; \tag{30}$$

the operator (26) – to translations

$$\rho_1 = \rho, \qquad \boldsymbol{B}_1 = \boldsymbol{B}, \qquad \boldsymbol{V}_1 = \boldsymbol{V}, \qquad P_1 = P + \tau. \tag{31}$$

Theorem 2. *Lie point transformations* (28)–(30) *are equivalent to the group G_m of Bogoyavlenskij transformations* (11).

The proof of Theorem 2 can also be found in [17].

Theorems 3, 4 establish connection of the infinite-dimensional symmetries of anisotropic plasmas with Lie symmetry method.

Theorem 3. *Consider the incompressible anisotropic CGL equilibrium system of equations* (9)–(10)*, where the density $\rho(\boldsymbol{r})$ and anisotropy factor $\tau(\boldsymbol{r})$ are constant on both magnetic field lines and streamlines. This system admits the infinitesimal operators*

$$X^{(1)} = M(\boldsymbol{r})\left(\sum_{k=1}^{3} B_k \frac{1/\mu - \tau}{\rho}\frac{\partial}{\partial V_k} + \sum_{k=1}^{3} V_k \frac{\partial}{\partial B_k} - \frac{1}{\mu}(\boldsymbol{V}\cdot\boldsymbol{B})\frac{\partial}{\partial p_\perp}\right), \tag{32}$$

$$X^{(2)} = \sum_{k=1}^{3} V_k \frac{\partial}{\partial V_k} + \sum_{k=1}^{3} B_k \frac{\partial}{\partial B_k} + 2P\frac{\partial}{\partial p_\perp}, \tag{33}$$

$$X^{(3)} = N(\boldsymbol{r})\left(2\rho\frac{\partial}{\partial\rho} - \sum_{k=1}^{3} V_k\frac{\partial}{\partial V_k}\right), \tag{34}$$

$$X^{(4)} = L(\boldsymbol{r})\left(2(1/\mu-\tau)\frac{\partial}{\partial\tau} - \sum_{k=1}^{3} B_k\frac{\partial}{\partial B_k} + \frac{B^2}{\mu}\frac{\partial}{\partial p_\perp}\right), \tag{35}$$

$$X^{(5)} = \frac{\partial}{\partial p_\perp}. \tag{36}$$

These operators form a basis of the Lie algebra of infinitesimal operators in the class of Lie point transformations $\{\boldsymbol{x}' = \boldsymbol{x},\ \boldsymbol{u}' = \boldsymbol{g}(\boldsymbol{u}, a)\}$. *Here* $L(\boldsymbol{r})$, $M(\boldsymbol{r})$, $N(\boldsymbol{r})$ *are arbitrary smooth functions constant on both magnetic field lines and streamlines.*

This theorem is proven exactly the same way as Theorem 1, by replacing the arbitrary functions of the transformations (13), (14) with exponents containing a parameter and differentiating by it.

The analog of Theorem 2 is also true for incompressible CGL plasma equilibria:

Theorem 4. *Lie point transformations defined by* (32)–(36) *are equivalent to the group* G *of Bogoyavlenskij transformations* (13), (14).

To prove this theorem, one needs to follow the sequence of steps of proof of Theorem 2, replacing MHD equilibrium infinitesimal operators by operators (32)–(36).

5 Summary

The isotropic and anisotropic plasma equilibrium equations (1), (2), (4), (5) in the incompressible case (3) possess infinite-dimensional families of intrinsic symmetries (11), (13), which are the richest known classes of transformations for these equations. These symmetries form Abelian groups $G_m = A_m \oplus A_m \oplus R^+ \oplus Z_2 \oplus Z_2 \oplus Z_2$ and $G = A_m \oplus A_m \oplus A_m \oplus R^+ \oplus Z_2 \oplus Z_2 \oplus Z_2 \oplus Z_2$ with eight and sixteen connected components respectively.

It is important that both of these groups of symmetries are implied by the Lie point transformations of these equations, and are thus obtainable from the standard procedure of Lie group analysis, which is applicable to any system of PDEs with sufficiently smooth coefficients.

The Lie procedure in application to MHD equilibria is described in Section 3. Every solution to a system of PDEs with n variables and m unknown functions represents a manifold Ω^1 in $(m+n+mn)$-dimensional jet space $X\times U\times U_1$ of independent and dependent variables $\boldsymbol{x}$, $\boldsymbol{u}$ and partial derivatives u_i^k (15). The Lie procedure consists in finding vector fields $\boldsymbol{v}$ (17) tangent to Ω^1. These vector fields serve as infinitesimal transformation group generators. Their components ξ^i, η^j (18) are functions of all independent and dependent variables. The equations (22) for determining the tangent vector field components are the conditions of invariance of the solution manifold Ω^1 under the action of $\boldsymbol{v}$.

To find the above Bogoyavlenskij symmetries for MHD and CGL equilibria, one must take into account the fact that in the general case ideal plasma domain is spanned by nested 2-dimensional magnetic surfaces – surfaces tangent to plasma velocity and magnetic field [16]. The arbitrary functions of Bogoyavlenskij symmetries are functions constant on such magnetic surfaces.

The operators (23)–(26) admissible by incompressible MHD equilibria form a basis of the Lie algebra of infinitesimal operators corresponding to the subgroup $\{\boldsymbol{x}' = \boldsymbol{x},\ \boldsymbol{u}' = \boldsymbol{g}(\boldsymbol{u}, a)\}$ of the group (16) of all Lie point transformations.

The same statement is true for the operators (32)–(36) and incompressible MHD equilibrium equations.

Theorems 2 and 4 show that the transformations generated by infinitesimal operators from Theorems 1, 3 are equivalent to the groups G_m, G of Bogoyavlenskij symmetries for MHD and CGL equilibria respectively.

This result illustrates that the general Lie approach of analyzing systems of partial differential equations is capable of revealing highly non-trivial intrinsic transformations that may have great importance in applications, as is the case for Bogoyavlenskij symmetries.

A Discussion on the Different Notions of Symmetry of Differential Equations

Giampaolo CICOGNA

Dipartimento di Fisica "E. Fermi" dell'Università and I.N.F.N. Sez. di Pisa,
Via Buonarroti 2, Ed. B-C, I–56127 – Pisa, Italy
E-mail: *cicogna@df.unipi.it*

A discussion is presented, within a simple unifying scheme, about different types of symmetry of PDE's, with the introduction and a precise characterization of the notions of "standard" and "weak" conditional symmetries, together with their relationship with exact and partial symmetries. An extensive use of "symmetry-adapted" variables is made; some clarifying examples are also provided.

1 Introduction

This paper is essentially a presentation of a unifying and comprehensive scheme, where several different notions of symmetry for differential problems may be considered and compared. In particular, this approach will permit the introduction of "subtler" notions of conditional symmetries (or "nonclassical symmetries ") [1–5], with a clear distinction and characterization of these symmetries and of other related concepts, including the more recently introduced notions of "partial symmetries" [6] (see also [7, 8]), and of "hidden symmetries" (see e.g. [9, 10]).

For simplicity, we will consider here only the case of partial differential equations (PDE)

$$\Delta \equiv \Delta_a\big(x, u^{(m)}\big) = 0 \qquad (a = 1, \dots, \nu) \tag{1}$$

for the q functions $u_\alpha = u_\alpha(x)$ of the p variables x_i (as usual, $u^{(m)}$ denotes the functions u_α together with their x derivatives up to the order m), and only "geometrical" or Lie-point symmetries, i.e. symmetries generated by vector fields of the form (sum over repeated indices)

$$X = \xi_i(x, u)\frac{\partial}{\partial x_i} + \phi_\alpha(x, u)\frac{\partial}{\partial u_\alpha} \tag{2}$$

although the relevant results could be suitably extended also to other types of symmetries, as generalized or Bäcklund, potential or nonlocal symmetries, whose importance is well known and also recently further emphasized (cf. e.g. [11–14]).

2 Exact symmetries

Let us start with the basic and standard definition, with the usual nondegeneracy and regularity assumptions tacitly understood (see [15–19]):

Definition 1. A system of PDE $\Delta_a\big(x, u^{(m)}\big) = 0$ is said to admit the Lie-point symmetry generated by the vector field X (or to be *symmetric* under X) if the following condition

$$X^*(\Delta)|_{\Delta=0} = 0 \tag{3}$$

is satisfied, or – equivalently (at least under mild hypotheses) – if there are functions $G = G_{ab}(x, u^{(m)})$ such that

$$(X^*(\Delta))_a = G_{ab}\,\Delta_b. \tag{4}$$

We simply denote by X^* the "appropriate" prolongation of X for the equation at hand, or – alternatively – its infinite prolongation (indeed, only a finite number of terms will appear in calculations).

Let us also give this other definition:

Definition 2. A system of PDE as before is said to be *invariant* under X if

$$X^*(\Delta) = 0. \tag{5}$$

For instance, the Laplace equation $u_{xx} + u_{yy} = 0$ is *invariant* under the rotation symmetry $X = y\partial/\partial x - x\partial/\partial y$; the heat equation $u_t = u_{xx}$ is *symmetric* but *not* invariant under

$$X = 2t\frac{\partial}{\partial x} - xu\frac{\partial}{\partial u}$$

indeed one has $X^*(u_t - u_{xx}) = -x(u_t - u_{xx})$.

We then have:

Theorem 1. *Let $\Delta = 0$ be a nondegenerate system of PDE's, symmetric under a projectable vector field X, according to Definition 1. Then, there are new $p+q$ variables s, z and v, with $s \in \mathbb{R}$, $z \in \mathbb{R}^{p-1}$ and $v \equiv (v_1(s,z), \dots, v_q(s,z))$, and a new system of PDE's, say $K = 0$, with $K_a = S_{ab}(s, z, v^{(m)})\, \widetilde{\Delta}_b(s, z, v^{(m)})$ (where $v^{(m)}$ stands for $v(s,z)$ and its derivatives with respect to s and z, and $\widetilde{\Delta} = \widetilde{\Delta}(s, z, v^{(m)})$ is Δ when expressed in terms of the new variables s, z, v), which is locally* equivalent *to the initial system and is* invariant *(as in Definition 2) under the symmetry $X = \partial/\partial s$, i.e. $K_a = K_a(z, v^{(m)})$.*

Proof. (a sketch) Given the symmetry X, one has to introduce "canonical variables" (or symmetry-adapted variables) $s, z \equiv (z_1, \dots, z_{p-1})$, which are defined by

$$Xs \equiv \xi_i \frac{\partial s}{\partial x_i} + \phi_\alpha \frac{\partial s}{\partial u_\alpha} = 1, \qquad Xz_k = 0 \qquad (k = 1, \dots, p-1).$$

Using the method of characteristics, one also finds the q dependent variables $v = v_\alpha(s, z)$; once written in these coordinates, the symmetry field and all its prolongations are simply given by

$$\widetilde{X} = \widetilde{X}^* = \frac{\partial}{\partial s} \tag{6}$$

whereas the symmetry condition (Definition 1) becomes $\frac{\partial \widetilde{\Delta}}{\partial s}\Big|_{\widetilde{\Delta}=0} = 0$, or

$$\frac{\partial}{\partial s}\widetilde{\Delta}_a = G_{ab}\widetilde{\Delta}_b. \tag{7}$$

It is not difficult to show (cf. [20]) that for any $\widetilde{\Delta}_a$ satisfying the system (7) there are smooth locally invertible functions S_{ab} such that the combinations $K_a := S_{ab}\widetilde{\Delta}_b$ are independent of s, as claimed. We have assumed here for convenience that the vector fields X are "projectable", or – more explicitly – that the functions ξ in (2) do not depend on u (as happens in most cases in the study of PDE's) in order to simplify calculations in the introduction of the canonical coordinates, and to get a more direct relationship between symmetries and symmetry-invariant solutions (for a discussion on this point, cf. [21]). ■

See [22] for a result in an analogous problem, although with different aim (i.e., constructing equations invariant under a given Lie algebra). It should be also emphasized that the result in Theorem 1 is not the same as (but is related to and includes in particular) the well known result concerning the reduction of the given equations to X-invariant equations for the invariant

variables $w(z)$: indeed, introducing the new "symmetry-adapted" variables s, z and $v(s,z)$, we have transformed the equations into *equivalent* equations for $v(s,z)$. If one now *further* assumes that $\partial v/\partial s = 0$, i.e. if one looks for the $X-$invariant solutions where $v = w(z)$, then the equations $K_a = 0$ become a system of equations

$$K_a^{(0)}\big(z, w^{(m)}\big) = 0 \tag{8}$$

involving only the variables z and functions depending only on z (see [23] for a general discussion on the reduction procedure).

3 "Standard" and "weak" conditional symmetries, and related notions

Let us now consider the case of non-exact symmetries. A fundamental and largely comprehensive notion has been introduced by Fushchych [24]: let us say that X is a *conditional symmetry of the equation* $\Delta = 0$ *in the sense of Fushchych* if there is a supplementary equation $E = 0$ such that X is an exact symmetry of the system $\Delta = E = 0$.

The simplest and more common case is obtained choosing as supplementary equation the "side condition" or "invariant surface condition"

$$X_Q u \equiv \xi_i \frac{\partial u}{\partial x_i} - \phi = 0, \tag{9}$$

where X_Q is the symmetry written in "evolutionary form" [16]: this corresponds to the usual (properly called) conditional symmetry (CS) (also called Q-conditional symmetry), and the above condition indicates that we are looking precisely for solutions which are *invariant* under X.

To avoid unessential complications with notations, we will consider from now on only the case of a single PDE $\Delta = 0$ for a single unknown function $u(x)$. The extension to more general cases is in principle completely straightforward.

It is known that the above definition of CS suffers from some intrinsic difficulties, essentially due to the necessity of introducing and dealing with the differential consequences of (9) (for a discussion of this point, see e.g. [16, 25, 26], and [27–29] for a more complete definition). Related to these difficulties is the quite embarrassing sentence by Olver and Rosenau [25] (see also [26]), which says – essentially – that, given any differential equation, *any* vector field X is a CS, and *any* solution of the equation is an invariant solution under some X.

To clarify this point, we will introduce a subtler definition of CS. This will be made resorting once again to the canonical coordinates s, z, $v = v(s,z)$, introduced in the proof of Theorem 1. First of all, in these coordinates the invariance condition $X_Q v = 0$ becomes

$$\frac{\partial v}{\partial s} = 0 \tag{10}$$

and the condition of CS takes the simple form (let us now retain for simplicity the same notation Δ, instead of $\widetilde{\Delta}$, also in the new coordinates)

$$\frac{\partial \Delta}{\partial s}\Big|_{\Sigma} = 0 \tag{11}$$

here Σ stands for the set of the simultaneous solutions of $\Delta = 0$ and $v_s = \partial v/\partial s = 0$, together with the derivatives of v_s with respect to all the variables s and z_k. Introducing the global notation $v_s^{(\ell)}$ to indicate v_s, v_{ss}, v_{sz_k} etc., we shall say that $X = \partial/\partial s$ is a CS in *standard sense* if the equation takes the form

$$\Delta = R\big(s, z, v^{(m)}\big) K\big(z, v^{(m)}\big) + \sum_{\ell} \Theta_\ell\big(s, z, v^{(m)}\big)\, v_s^{(\ell)} = 0, \tag{12}$$

where the point to be emphasized is that K does not depend *explicitly* on s, and R, K do not contain $v_s^{(\ell)}$. It is then clear that, if one now looks for solutions of $\Delta = 0$ which are independent on s, i.e. such that $v_s^{(\ell)} = 0$, or of the form $v = w(z)$, then equation (12) becomes a "reduced" equation $K^{(0)}(z, w^{(m)}) = 0$, just as in the exact symmetry case.

But this is clearly only a special case. Indeed, the equation $\Delta = 0$ may also take the form

$$\Delta = \sum_{r=1}^{\sigma} s^{r-1} K_r\big(z, v^{(m)}\big) + \sum_{\ell} \Theta_\ell\big(s, z, v^{(m)}\big)\, v_s^{(\ell)} = 0, \tag{13}$$

where the part not containing $v_s^{(\ell)}$ is a polynomial in the variable s, with coefficients K_r not depending explicitly on s, or also – more in general (with some different regrouping of the terms containing s into linearly and functionally independent terms R_r)

$$\Delta = \sum_{r=1}^{\sigma} R_r\big(s, z, v^{(m)}\big)\, K_r\big(z, v^{(m)}\big) + \sum_{\ell} \Theta_\ell\big(s, z, v^{(m)}\big)\, v_s^{(\ell)} = 0. \tag{14}$$

In this case, if one looks for X-invariant solutions $w(z)$ of $\Delta = 0$, one is faced with the system of reduced equations (not containing s nor functions of s)

$$K_r^{(0)}\big(z, w^{(m)}\big) = 0, \qquad r = 1, \dots, \sigma. \tag{15}$$

Assume that this system admits some solution (it is known that the existence of invariant solutions is by no means guaranteed in general, neither for "standard" CS, nor for "exact" Lie symmetries), we will say that X is *weak CS of order* σ.

We now see that the set of the solutions of the above system can be characterized equivalently as the set of the solutions of the system

$$\Delta = 0, \quad \frac{\partial \Delta}{\partial s} = 0, \quad \dots, \quad \frac{\partial^{\sigma-1}\Delta}{\partial s^{\sigma-1}} = 0, \quad v_s^{(\ell)} = 0. \tag{16}$$

Coming back to the original coordinates x, u, the set of conditions (16) becomes

$$\Delta = \Delta^{(1)} = \dots = \Delta^{(\sigma-1)} = 0, \qquad X_Q u = 0, \tag{17}$$

where

$$\Delta^{(1)} := X^*(\Delta), \qquad \Delta^{(2)} := X^*\big(\Delta^{(1)}\big), \qquad \dots \tag{18}$$

(as already pointed out, also the differential consequences of $X_Q u = 0$ must be taken into account), and a CS of order σ can be characterized by the condition

$$X^*(\Delta)|_{\Sigma_\sigma} = 0, \tag{19}$$

where Σ_σ is the set (if not empty, of course) of the solutions of the system (17).

We can summarize our discussion in the following form.

Proposition 1. *Given a PDE $\Delta = 0$, a projectable vector field X is a "standard" conditional symmetry for the equation if it is a symmetry for the system*

$$\Delta = 0, \qquad X_Q u = 0$$

and this corresponds to the existence of a reduced equation in $p-1$ independent variables, which – if admits solutions – gives X-invariant solutions of $\Delta = 0$. A vector field X is a "weak" CS (of order σ) if it is a symmetry of the system

$$\Delta = 0, \quad \Delta^{(1)} := X^*(\Delta) = 0, \quad \Delta^{(2)} := X^*\big(\Delta^{(1)}\big) = 0, \quad \dots, \quad \Delta^{(\sigma-1)} = 0, \quad X_Q u = 0$$

and this corresponds to the existence of a system of σ reduced equations, which – if admits solutions – gives $X-$invariant solutions of $\Delta = 0$. Introducing $X-$adapted variables s, z, such that $Xs = 1$, $Xz = 0$, the PDE has the form (12) *in the case of standard CS, or* (14) *in the case of weak CS.*

If one neglects the invariance condition $X_Q u = 0$, one is actually dealing with the case of *partial* symmetries. Indeed (see [6–8]), X is precisely a partial symmetry of order σ if X is a symmetry of the system

$$\Delta = \Delta^{(1)} = \cdots = \Delta^{(\sigma-1)} = 0. \tag{20}$$

If this is the case, X maps one into another the solutions of the system (20), which is then a "symmetric set of solutions of $\Delta = 0$" [7]. In particular, if in this set there are some solutions which are left fixed by X, then X is also a CS (either standard or weak) of $\Delta = 0$.

We can then rephrase the Olver–Rosenau statement [25] in the form:

Proposition 2. *Any vector field X is either an exact, or a standard CS, or a weak CS. Similarly, any X is either an exact or a partial symmetry.*

It is well known that the set of the solutions which can be obtained in this way may be empty or contain only trivial solutions (e.g., $u = \text{const}$): it is clear that the choice of good candidates for these "non-exact" symmetry generators should be guided by some reasonable criterion and motivated guess. It is also clear that all the notions of non-exact symmetries considered above can be viewed as special cases of CS in the sense of Fushchych.

In all the above discussion, we have considered the case of a single vector field X; clearly, the situation becomes richer and richer if more than one vector field is taken into consideration. First of all, the reduction procedure itself must be adapted and refined when the given equation admits an algebra of symmetries of dimension larger than 1 (possibly infinite): for a recent discussion see [30]. Secondly, for instance, it can happen that the reduced equations (8) or (15) may admit some new symmetry Y not shared by the original equation $\Delta = 0$: this is (essentially) the case of "hidden symmetries" [9,10]. Different reduction procedures have been also proposed, based on the introduction of multiple suitable differential constraints: see, e.g., [11,31–33], and also [17].

4 Examples

We will give here some simple examples, to illustrate the properties of the different types of symmetries introduced above, and the different solutions that can be obtained accordingly.

Example 1. Consider the equation, proposed by Popovych [29]

$$u_t + u_{xx} - u + t(u_x - u) = 0, \qquad u = u(x,t).$$

The vector field $X = \partial/\partial t$ is not an exact nor a standard CS, but is a weak CS, indeed the system of equations (15) (here $s = t$) becomes $u_{xx} = u$, $u_x = u$, with solution $u = c\exp(x)$. The same vector field $X = \partial/\partial t$ is a weak CS also for this variation of the above equation:

$$u_t - u_{tt} + u_{xx} - u + t(u_x - u) = 0$$

with the same solution as above. But X is now also a partial symmetry: indeed, the equation $\Delta^{(1)} = 0$ is now $u_x - u = 0$, and combining it with $\Delta = 0$ we find the more general solution $u = c\exp(x) + c_1\exp(x+t)$. Considering this other variation of the Popovych example

$$t^2(u_t - u) + u_{xx} - u + t(u_x - u) = 0$$

here $X = \partial/\partial t$ is only a partial symmetry, leading to the solution $u = c\exp(x+t)$ (strictly speaking, it is also a weak CS, but producing only the trivial solution $u = 0$!).

Example 2. It is well known that the Korteweg-de Vries equation

$$u_t + u_{xxx} + uu_x = 0, \qquad u = u(x,t)$$

does not admit (standard) CS, apart from its exact symmetries. There are however weak CS; e.g. the scaling

$$X = 2x\frac{\partial}{\partial x} + t\frac{\partial}{\partial t} + u\frac{\partial}{\partial u}$$

is an exact symmetry for the system $\Delta = 0$, $\Delta^{(1)} := X^*(\Delta) = 0$, $X_Q u = 0$, which means that this is a weak CS, giving the scaling-invariant solution $u = x/t$. But also, if we neglect the invariance condition $X_Q u = 0$, we obtain the (clearly larger) symmetric set of solutions $u = (x + c_1)/(t + c_2)$, showing that the above X is also a partial symmetry.

Example 3. The symmetry properties of the Boussinesq equation

$$u_{tt} + u_{xxxx} + uu_{xx} + u_x^2 = 0, \qquad u = u(x,t) \tag{21}$$

have been the object of several papers (see e.g. [11, 34, 35]). For what concerns standard CS, writing the general vector field in the form

$$X = \xi(x,t,u)\frac{\partial}{\partial x} + \tau(x,t,u)\frac{\partial}{\partial t} + \phi(x,t,u)\frac{\partial}{\partial u} \tag{22}$$

a complete list of CS has been given both for the case $\tau \neq 0$ (and therefore, without any restriction, $\tau = 1$) [34] and for the case $\tau = 0$ [35, 36]; it has been also shown that the invariant solutions under these CS are precisely those found by means of the "direct method", which is not based on (but clearly related to) symmetry properties [34, 35, 37].

To complete the analysis, one can also look for symmetries with $\xi = 0$. It is not difficult to verify that no standard CS of this form is admitted. There are however weak CS: an example is

$$X = \frac{\partial}{\partial t} + \left(\frac{1}{t^2} - \frac{2u}{t}\right)\frac{\partial}{\partial u} \tag{23}$$

one obtains from this: $s = t$, $z = x$ and $u(x,t) = t^{-1} + t^{-2}v(x,t)$, giving

$$vv_{xx} + v_x^2 + 6v + t(v_{xx} + 2) + t^2 v_{xxxx} - 4tv_t + t^2 v_{tt} = 0 \tag{24}$$

which is precisely of the form (14) (the role of s is played here by t). Looking indeed for solutions with $v = w(x)$, one gets a system of three ODE's

$$ww_{xx} + w_x^2 + 6w = 0, \qquad w_{xx} + 2 = 0, \qquad w_{xxxx} = 0$$

(cf. (16)), admitting the common solution $w = -x^2$ and giving the (quite elementary) solution $u = 1/t - x^2/t^2$ of the Boussinesq equation.

Another example of weak CS for the Boussinesq equation is the following

$$X = t^2\frac{\partial}{\partial x} + \frac{\partial}{\partial t} - \left(2x + \frac{10}{3}t^3\right)\frac{\partial}{\partial u} \tag{25}$$

now $s = t$, $z = x - t^3/3$ and $u = -2sz - s^4 + v(s,z)$. The additional equations $\Delta^{(1)} := X^*(\Delta) = 0$ etc.: now become

$$\Delta^{(1)} = -10t - 3u_x - 2tu_{xt} - \frac{5}{3}t^3 u_{xx} - xu_{xx} = 0, \qquad \Delta^{(2)} = 2 + u_{xt} + t^2 u_{xx} = 0 \tag{26}$$

and taking into account also the invariance condition $X_Q u = 0$, we easily conclude that this is a weak CS of order $\sigma = 3$ and obtain the solution

$$u(x,t) = -\frac{t^4}{3} - 2tx - \frac{12}{(x - t^3/3)^2} \tag{27}$$

If instead we do *not* impose the invariance condition $X_Q u = 0$ and solve the three equations (21), (26), we find, in addition to the invariant solution (27), also the following family of solutions $u(x,t) = -t^4/3 + c_1 t - 2tx + c_2$, showing that the above symmetry is also a partial symmetry.

The differential first-order invariants for all non-splitting subgroups of the generalized Poincaré group $P(1,4)$ are constructed.

1 Introduction

The differential invariants play an important role in geometry, group analysis of differential equations, theoretical and mathematical physics, mechanics, gas dynamics, etc. They have been studied in many works (see, for example [1–14]). In particular, the papers [12–14] are devoted to the construction of the first-order differential invariants for the splitting subgroups [15–17] of the generalized Poincaré group $P(1,4)$. The group $P(1,4)$ is a group of rotations and translations of the five-dimensional Minkowski space $M(1,4)$. This group is very useful in the theoretical and mathematical physics [18–20].

The objective of this paper is to present some of the new results concerning the differential first-order invariants for the non-splitting subgroups [17, 21, 22] of the group $P(1,4)$.

For this purpose, we have to consider the Lie algebra of the group $P(1,4)$.

2 The Lie algebra of the group $P(1,4)$ and its non-conjugate subalgebras

The Lie algebra of the group $P(1,4)$ is generated by the 15 basis elements $M_{\mu\nu} = -M_{\nu\mu}$ $(\mu,\nu = 0,1,2,3,4)$ and P'_μ $(\mu = 0,1,2,3,4)$, satisfying the commutation relations

$$\left[P'_\mu, P'_\nu\right] = 0, \qquad \left[M'_{\mu\nu}, P'_\sigma\right] = g_{\mu\sigma}P'_\nu - g_{\nu\sigma}P'_\mu,$$
$$\left[M'_{\mu\nu}, M'_{\rho\sigma}\right] = g_{\mu\rho}M'_{\nu\sigma} + g_{\nu\sigma}M'_{\mu\rho} - g_{\nu\rho}M'_{\mu\sigma} - g_{\mu\sigma}M'_{\nu\rho},$$

where $g_{00} = -g_{11} = -g_{22} = -g_{33} = -g_{44} = 1$, $g_{\mu\nu} = 0$, if $\mu \neq \nu$. Here, and in the following: $M'_{\mu\nu} = iM_{\mu\nu}$.

Let us consider the following representation of the Lie algebra of the group $P(1,4)$:

$$P'_0 = \frac{\partial}{\partial x_0}, \qquad P'_1 = -\frac{\partial}{\partial x_1}, \qquad P'_2 = -\frac{\partial}{\partial x_2}, \qquad P'_3 = -\frac{\partial}{\partial x_3},$$
$$P'_4 = -\frac{\partial}{\partial x_4}, \qquad M'_{\mu\nu} = -\left(x_\mu P'_\nu - x_\nu P'_\mu\right).$$

Next, we will use the following basis elements:

$$G = M'_{40}, \qquad L_1 = M'_{32}, \qquad L_2 = -M'_{31}, \qquad L_3 = M'_{21},$$
$$P_a = M'_{4a} - M'_{a0}, \qquad C_a = M'_{4a} + M'_{a0} \quad (a = 1, 2, 3),$$
$$X_0 = \frac{1}{2}\left(P'_0 - P'_4\right), \qquad X_k = P'_k \quad (k = 1, 2, 3), \qquad X_4 = \frac{1}{2}\left(P'_0 + P'_4\right).$$

We used the method proposed in [23] to study the subgroup structure of the group $P(1,4)$.

Non-conjugate subgroups of the group $P(1,4)$ have been described in [15–17, 21, 22]. The conjugation was considered under the group $P(1,4)$.

From the results obtained it follows that the Lie algebra of the group $P(1,4)$ contains, as subalgebras, the Lie algebra of the Poincaré group $P(1,3)$ and the Lie algebra of the extended Galilei group $\widetilde{G}(1,3)$ [20]. The Lie algebra of the group $\widetilde{G}(1,3)$ has the following basis elements: $L_1,\ L_2,\ L_3,\ P_1,\ P_2,\ P_3,\ X_0,\ X_1,\ X_2,\ X_3,\ X_4$.

3 The differential first-order invariants of the non-splitting subgroups of the group $P(1,4)$

The functional bases of the differential first-order invariants have been constructed for all non-splitting subgroups of the group $P(1,4)$. Since it is impossible to present here all the results obtained, only some of them are given in this section.

Below, for some of the non-splitting subalgebras of the Lie algebra of the group $P(1,4)$ we write their respective basis elements and corresponding functional basis of the differential invariants.

One-dimensional subalgebras

1. $\langle P_3 + X_1 \rangle$,

$$J_1 = x_2, \quad J_2 = x_0 + x_4, \quad J_3 = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2}, \quad J_4 = x_1 + \frac{x_3}{x_0 + x_4}, \quad J_5 = u,$$
$$J_6 = (x_0 + x_4)u_3 + (u_0 - u_4)x_3, \quad J_7 = u_1, \quad J_8 = u_2, \quad J_9 = u_0 - u_4,$$
$$J_{10} = u_0^2 - u_3^2 - u_4^2, \quad u_\mu \equiv \frac{\partial u}{\partial x_\mu}, \quad \mu = 0, 1, 2, 3, 4;$$

2. $\langle G + cX_1,\ c < 0 \rangle$,

$$J_1 = x_1 - c\ln(x_0 + x_4), \quad J_2 = x_2, \quad J_3 = x_3, \quad J_4 = (x_0^2 - x_4^2)^{1/2}, \quad J_5 = u,$$

4. $\langle G,\ L_3 + d_3 X_3,\ P_1,\ P_2,\ X_1,\ X_2,\ X_4,\ d_3 < 0 \rangle$,

$$J_1 = u, \quad J_2 = \frac{u_0 - u_4}{x_0 + x_4}, \quad J_3 = u_3, \quad J_4 = u_0^2 - u_1^2 - u_2^2 - u_4^2.$$

Eight-dimensional subalgebras

1. $\langle G + aX_3,\ L_3,\ P_1,\ P_2,\ P_3,\ X_1,\ X_2,\ X_4,\ a < 0\rangle$,

$$J_1 = u, \quad J_2 = \frac{x_0 + x_4}{u_0 - u_4}, \quad J_3 = a\ln(u_0 - u_4) - \frac{x_0 + x_4}{u_0 - u_4}u_3 - x_3,$$
$$J_4 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2;$$

2. $\langle P_1,\ P_2,\ P_3 + X_0,\ L_3 + \beta X_0,\ X_1,\ X_2,\ X_3,\ X_4,\ \beta < 0\rangle$,

$$J_1 = u, \quad J_2 = u_0 - u_4, \quad J_3 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2;$$

3. $\langle G,\ L_3 + bX_3,\ P_1,\ P_2,\ P_3,\ X_1,\ X_2,\ X_4,\ b < 0\rangle$,

$$J_1 = u, \quad J_2 = \frac{x_0 + x_4}{u_0 - u_4}, \quad J_3 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2;$$

4. $\langle L_3,\ P_1,\ P_2,\ P_3 + X_0,\ X_1,\ X_2,\ X_3,\ X_4\rangle$,

$$J_1 = u, \quad J_2 = x_0 + x_4 + \frac{u_3}{u_0 - u_4}, \quad J_3 = u_0 - u_4,$$
$$J_4 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2.$$

The results obtained can be used, for example, to construct the first-order differential equations in the space $M(1,4) \times R(u)$ with non-trivial symmetry groups. In particular, among them, there will be equations, which are invariant under the non-splitting subgroups of the Poincaré group $P(1,3)$, as well as equations which are invariant under the non-splitting subgroups of the extended Galilei group $\widetilde{G}(1,3)$.

On Symmetry Reduction of Some Classes of the First-Order Differential Equations in the Space $M(1,4) \times R(u)$

Volodymyr I. FEDORCHUK

Franko Lviv National University, 1 Universytets'ka Str., 79000 Lviv, Ukraine
E-mail: *fedorchukv@ukr.net*

The symmetry reduction of some classes of the first-order differential equations (in the space $M(1,4)\times R(u)$), invariant under splitting subgroups of the generalized Poincaré group $P(1,4)$, to differential equations with fewer independent variables are done.

1 Introduction

It is well known that among equations, important for theoretical and mathematical physics, there are also ones which have nontrivial symmetry groups. In the space $M(1,4) \times R(u)$ we have the linear and nonlinear wave equations and the Dirac equation. Here, and in what follows, $R(u)$ is the number axis of the dependent variable u. These equations are invariant under the generalized Poincaré group $P(1,4)$ (see, for example, [1–3]). The group $P(1,4)$ is a group of rotations and translations of the five-dimensional Minkowski space $M(1,4)$. This group has many applications in the theoretical and mathematical physics [1–3]. The group $P(1,4)$ has many subgroups used in the theoretical physics [4–6]. Among these subgroups there are the Poincaré group $P(1,3)$ and the extended Galilei group $\widetilde{G}(1,3)$ (see also [7]). Thus, the results obtained with the use of the subgroup structure of the group $P(1,4)$ will be useful in the relativistic and non-relativistic physics. Therefore, it is important from the physical and mathematical points of view, that we are able to construct, in the space $M(1,4) \times R(u)$, new differential equations invariant under continuous subgroups of the generalized Poincaré group $P(1,4)$. The paper [8] is devoted to the construction of the first-order differential equations invariant under splitting subgroups of the group $P(1,4)$, defined in the space $M(1,4) \times R(u)$.

In the present paper we continue to study this type of equations. We concentrate our attention on the symmetry reduction of the first-order differential equations, invariant under splitting subgroups of the group $P(1,4)$, to differential equations with fewer independent variables.

Our paper is organized as follows: in Section 2 we introduce some notations and results concerning the Lie algebra of the group $P(1,4)$, which are used in the next chapter. Section 3 presents our main results.

2 The Lie algebra of the group $P(1,4)$ and its subalgebras

The Lie algebra of the group $P(1,4)$ is given by the 15 basis elements $M_{\mu\nu} = -M_{\nu\mu}$ $(\mu,\nu = 0,1,2,3,4)$ and P'_μ $(\mu = 0,1,2,3,4)$, which satisfy the commutation relations

$$\begin{aligned}
&\left[P'_\mu, P'_\nu\right] = 0, \qquad \left[M'_{\mu\nu}, P'_\sigma\right] = g_{\mu\sigma}P'_\nu - g_{\nu\sigma}P'_\mu,\\
&\left[M'_{\mu\nu}, M'_{\rho\sigma}\right] = g_{\mu\rho}M'_{\nu\sigma} + g_{\nu\sigma}M'_{\mu\rho} - g_{\nu\rho}M'_{\mu\sigma} - g_{\mu\sigma}M'_{\nu\rho},
\end{aligned}$$

where $g_{00} = -g_{11} = -g_{22} = -g_{33} = -g_{44} = 1$, $g_{\mu\nu} = 0$, if $\mu \neq \nu$. Here, and in what follows, $M'_{\mu\nu} = iM_{\mu\nu}$.

We consider the following representation of the Lie algebra of the group $P(1,4)$:

$$P'_0 = \frac{\partial}{\partial x_0}, \qquad P'_1 = -\frac{\partial}{\partial x_1}, \qquad P'_2 = -\frac{\partial}{\partial x_2}, \qquad P'_3 = -\frac{\partial}{\partial x_3},$$
$$P'_4 = -\frac{\partial}{\partial x_4}, \qquad M'_{\mu\nu} = -\left(x_\mu P'_\nu - x_\nu P'_\mu\right).$$

Below, we will use the following basis elements:

$$G = M'_{40}, \qquad L_1 = M'_{32}, \qquad L_2 = -M'_{31}, \qquad L_3 = M'_{21},$$
$$P_a = M'_{4a} - M'_{a0}, \qquad C_a = M'_{4a} + M'_{a0} \quad (a = 1,2,3),$$
$$X_0 = \frac{1}{2}\left(P'_0 - P'_4\right), \qquad X_k = P'_k \quad (k = 1,2,3), \qquad X_4 = \frac{1}{2}\left(P'_0 + P'_4\right).$$

For the study of the subgroup structure of the group $P(1,4)$ we used the method proposed in [9]. Continuous subgroups of the group $P(1,4)$ have been described in [4–6].

3 The first-order differential equations in the space $M(1,4) \times R(u)$

In this section we present some of the new results concerning the first-order differential equations in the space $M(1,4) \times R(u)$.

The equations in the space $M(1,4) \times R(u)$, which are invariant under splitting subgroups of the group $P(1,4)$, can be written in the following form (see, for example [10–12]):

$$F(J_1, J_2, \ldots, J_t) = 0,$$

where F is an arbitrary smooth function of its arguments, $\{J_1, J_2, \ldots, J_t\}$ is a functional basis of the first-order differential invariants of splitting subgroups of the group $P(1,4)$.

The classes of the first-order differential equations in the space $M(1,4) \times R(u)$, which are invariant under splitting subgroups of the group $P(1,4)$, are constructed. Some of the results obtained have been presented in [8]. To study these classes of the differential equations, we used only their symmetry properties.

Taking into account the functional bases of the invariants of some splitting subgroups of the group $P(1,4)$, we have constructed the ansatzes, which reduce majority of the equations obtained to differential equations with fewer independent variables. The corresponding symmetry reduction has been done. Among the reduced equations there are one-, two-, three- and four-dimensional ones.

It is impossible to present here all the results obtained. Therefore, we will give a short review of the results concerning the symmetry reduction of the considered classes of differential equations to classes of ODEs.

Let us consider the classes of the first-order differential equations, which are constructed with the use of the functional bases of the first-order differential invariants containing two usual invariants. One of them always is u, since it is one of the invariants of the group $P(1,4)$. On the base of these two invariants we have constructed the ansatzes, which reduce the classes considered to classes of ODEs. The corresponding symmetry reduction is done. Among the considered classes there are ones which are invariant under the splitting subgroups of the group $\widetilde{G}(1,3)$. The Lie algebra of the group $\widetilde{G}(1,3)$ is generated by the following basis elements: L_1, L_2, L_3, P_1, P_2, P_3, X_0, X_1, X_2, X_3, X_4. We have 32 such classes of differential equations. From

among them, 17 classes have been reduced to the classes of functional equations. From these functional equations we can find solutions for the corresponding classes of differential equations.

Below, for some splitting subgroups of the group $P(1,4)$, we write the basis elements of their respective Lie algebras, the corresponding arguments $J_1, J_2, \ldots, J_t$ of the function F, the ansatzes obtained, as well as the reduced equation for each case.

1. $\langle P_1, P_2, P_3, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = u_1 + x_1\frac{u_0 - u_4}{x_0 + x_4}, \quad J_4 = u_2 + x_2\frac{u_0 - u_4}{x_0 + x_4},$$
$$J_5 = \frac{u_0 - u_4}{x_0 + x_4}x_3 + u_3, \quad J_6 = u_0 - u_4, \quad J_7 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2;$$
$$u = \varphi(\omega), \quad \omega = x_0 + x_4; \quad F\left(\omega, \varphi, 0, 0, 0, 0, 0\right) = 0; \quad u_\mu \equiv \frac{\partial u}{\partial x_\mu}, \quad \mu = 0, 1, 2, 3, 4;$$

2. $\langle P_1, P_2, X_3, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = u_1(x_0 + x_4) + x_1(u_0 - u_4),$$
$$J_4 = u_2(x_0 + x_4) + x_2(u_0 - u_4), \quad J_5 = u_3, \quad J_6 = u_0 - u_4,$$
$$J_7 = u_0^2 - u_1^2 - u_2^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = x_0 + x_4; \quad F\left(\omega, \varphi, 0, 0, 0, 0, 0\right) = 0;$$

3. $\langle P_3, X_1, X_2, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = (x_0 + x_4)u_3 + (u_0 - u_4)x_3, \quad J_4 = u_1,$$
$$J_5 = u_2, \quad J_6 = u_0 - u_4, \quad J_7 = u_0^2 - u_3^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = x_0 + x_4;$$
$$F\left(\omega, \varphi, 0, 0, 0, 0, 0\right) = 0;$$

4. $\langle L_3, P_1, P_2, P_3, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = \frac{u_0 - u_4}{x_0 + x_4}x_3 + u_3, \quad J_4 = \left(u_1 + x_1\frac{u_0 - u_4}{x_0 + x_4}\right)^2 +$$
$$+ \left(u_2 + x_2\frac{u_0 - u_4}{x_0 + x_4}\right)^2, \quad J_5 = u_0 - u_4, \quad J_6 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2;$$
$$u = \varphi(\omega), \quad \omega = x_0 + x_4; \quad F\left(\omega, \varphi, 0, 0, 0, 0\right) = 0;$$

5. $\langle L_3, P_1, P_2, X_3, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = \left(u_1 + x_1\frac{u_0 - u_4}{x_0 + x_4}\right)^2 + \left(u_2 + x_2\frac{u_0 - u_4}{x_0 + x_4}\right)^2,$$
$$J_4 = u_3, \quad J_5 = u_0 - u_4, \quad J_6 = u_0^2 - u_1^2 - u_2^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = x_0 + x_4;$$
$$F\left(\omega, \varphi, 0, 0, 0, 0\right) = 0;$$

6. $\langle L_3, P_3, X_1, X_2, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = (x_0 + x_4)u_3 + (u_0 - u_4)x_3,$$
$$J_4 = u_0 - u_4, \quad J_5 = u_1^2 + u_2^2, \quad J_6 = u_0^2 - u_3^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = x_0 + x_4;$$
$$F\left(\omega, \varphi, 0, 0, 0, 0\right) = 0;$$

7. $\langle L_3 - P_3, P_1, P_2, X_1, X_2, X_4\rangle$,

$$J_1 = x_0 + x_4, \quad J_2 = u, \quad J_3 = (x_0 + x_4)u_3 + (u_0 - u_4)x_3, \quad J_4 = u_0 - u_4,$$
$$J_5 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = x_0 + x_4; \quad F\left(\omega, \varphi, 0, 0, 0\right) = 0.$$

However, among the classes of the first-order differential equations, which are invariant under the splitting subgroups of the group $\widetilde{G}(1,3)$, there exist classes, which are reduced to classes of ODEs. We obtained 15 such classes. Let us present some of them.

1. $\langle L_3, X_0, X_3, X_4\rangle$,

$$J_1=\left(x_1^2+x_2^2\right)^{1/2},\quad J_2=u,\quad J_3=x_1u_2-x_2u_1,\quad J_4=u_0,\quad J_5=u_3,\quad J_6=u_4,$$
$$J_7=u_1^2+u_2^2;\quad u=\varphi(\omega),\quad \omega=\left(x_1^2+x_2^2\right)^{1/2};\quad F\left(\omega,\varphi,0,0,0,0,\left(\varphi'\right)^2\right)=0;$$

2. $\langle X_1, X_2, X_3, X_4\rangle$,

$$J_1=x_0+x_4,\quad J_2=u,\quad J_3=u_0,\quad J_4=u_1,\quad J_5=u_2,\quad J_6=u_3,\quad J_7=u_4;$$
$$u=\varphi(\omega),\quad \omega=x_0+x_4;\quad F\left(\omega,\varphi,\varphi',0,0,0,\varphi'\right)=0;$$

3. $\langle L_1, L_2, L_3, X_0, X_4\rangle$,

$$J_1=\left(x_1^2+x_2^2+x_3^2\right)^{1/2},\quad J_2=u,\quad J_3=x_1u_1+x_2u_2+x_3u_3,\quad J_4=u_0,\quad J_5=u_4,$$
$$J_6=u_1^2+u_2^2+u_3^2;\quad u=\varphi(\omega),\quad \omega=\left(x_1^2+x_2^2+x_3^2\right)^{1/2};\quad F\left(\omega,\varphi,\omega\varphi',0,0,\left(\varphi'\right)^2\right)=0;$$

4. $\langle L_1, L_2, L_3, P_1, P_2, P_3, X_4\rangle$,

$$J_1=x_0+x_4,\quad J_2=u,\quad J_3=(u_0-u_4)(x_0^2-x_1^2-x_2^2-x_3^2-x_4^2)-2(x_0u_0+x_1u_1$$
$$+x_2u_2+x_3u_3+x_4u_4)(x_0+x_4),\quad J_4=u_0-u_4,\quad J_5=u_0^2-u_1^2-u_2^2-u_3^2-u_4^2;$$
$$u=\varphi(\omega),\quad \omega=x_0+x_4;\quad F\left(\omega,\varphi,-2\omega^2\varphi',0,0\right)=0.$$

The remainder of the considered classes of the first-order differential equations are invariant under the splitting subgroups of the group $P(1,4)$, which do not belong to the splitting subgroups of the group $\widetilde{G}(1,3)$. We have 43 such classes. All these classes are reduced to ODEs. Now, we give some examples of this type of reduction.

1. $\langle G, P_1, P_2, P_3\rangle$,

$$J_1=(x_0^2-x_1^2-x_2^2-x_3^2-x_4^2)^{1/2},\quad J_2=u,\quad J_3=\frac{u_0-u_4}{x_0+x_4},\quad J_4=x_1+u_1\frac{x_0+x_4}{u_0-u_4},$$
$$J_5=x_2+u_2\frac{x_0+x_4}{u_0-u_4},\quad J_6=x_3+\frac{x_0+x_4}{u_0-u_4}u_3,\quad J_7=u_0^2-u_1^2-u_2^2-u_3^2-u_4^2;$$
$$u=\varphi(\omega),\quad \omega=(x_0^2-x_1^2-x_2^2-x_3^2-x_4^2)^{1/2};\quad F\left(\omega,\varphi,\frac{\varphi'}{\omega},0,0,0,\left(\varphi'\right)^2\right)=0;$$

2. $\langle G, P_3, L_3, X_4\rangle$,

$$J_1=\left(x_1^2+x_2^2\right)^{1/2},\quad J_2=u,\quad J_3=x_1u_2-x_2u_1,\quad J_4=\frac{u_0-u_4}{x_0+x_4},\quad J_5=\frac{u_0-u_4}{x_0+x_4}x_3+u_3,$$
$$J_6=u_1^2+u_2^2,\quad J_7=u_0^2-u_3^2-u_4^2;\quad u=\varphi(\omega),\quad \omega=\left(x_1^2+x_2^2\right)^{1/2};$$
$$F\left(\omega,\varphi,0,0,0,\left(\varphi'\right)^2,0\right)=0;$$

3. $\langle G, P_1, P_2, X_3\rangle$,

$$J_1=\left(x_0^2-x_1^2-x_2^2-x_4^2\right)^{1/2},\quad J_2=u,\quad J_3=\frac{u_0-u_4}{x_0+x_4},\quad J_4=x_1+u_1\frac{x_0+x_4}{u_0-u_4},$$
$$J_5=x_2+u_2\frac{x_0+x_4}{u_0-u_4},\quad J_6=u_3,\quad J_7=u_0^2-u_1^2-u_2^2-u_4^2;\quad u=\varphi(\omega),$$

$\omega = \left(x_0^2 - x_1^2 - x_2^2 - x_4^2\right)^{1/2}; \quad F\left(\omega, \varphi, \dfrac{\varphi'}{\omega}, 0, 0, 0, \left(\varphi'\right)^2\right) = 0;$

4. $\langle G, L_3, X_3, X_4\rangle$,

$J_1 = \left(x_1^2 + x_2^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = x_1u_2 - x_2u_1, \quad J_4 = (x_0 + x_4)(u_0 + u_4),$
$J_5 = u_3, \quad J_6 = u_1^2 + u_2^2, \quad J_7 = u_0^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_1^2 + x_2^2\right)^{1/2};$
$F\left(\omega, \varphi, 0, 0, 0, \left(\varphi'\right)^2, 0\right) = 0;$

5. $\langle G, P_3, X_1, X_2\rangle$,

$J_1 = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = \dfrac{u_0 - u_4}{x_0 + x_4}, \quad J_4 = \dfrac{u_0 - u_4}{x_0 + x_4}x_3 + u_3,$
$J_5 = u_1, \quad J_6 = u_2, \quad J_7 = u_0^2 - u_3^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2};$
$F\left(\omega, \varphi, \dfrac{\varphi'}{\omega}, 0, 0, 0, \left(\varphi'\right)^2\right) = 0;$

6. $\langle G, X_1, X_2, X_3\rangle$,

$J_1 = \left(x_0^2 - x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = (x_0 + x_4)(u_0 + u_4), \quad J_4 = u_1, \quad J_5 = u_2,$
$J_6 = u_3, \quad J_7 = u_0^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_0^2 - x_4^2\right)^{1/2};$
$F\left(\omega, \varphi, \omega\varphi', 0, 0, 0, \left(\varphi'\right)^2\right) = 0;$

7. $\langle P_3 + C_3 + 2L_3, X_1, X_2, X_0 + X_4\rangle$,

$J_1 = \left(x_3^2 + x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = x_3u_4 - x_4u_3, \quad J_4 = x_3u_2 - x_4u_1, \quad J_5 = u_0,$
$J_6 = u_1^2 + u_2^2, \quad J_7 = u_3^2 + u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_3^2 + x_4^2\right)^{1/2};$
$F\left(\omega, \varphi, 0, 0, 0, 0, \left(\varphi'\right)^2\right) = 0;$

8. $\langle L_1 + \dfrac{1}{2}(P_1 + C_1), L_2 + \dfrac{1}{2}(P_2 + C_2), L_3 + \dfrac{1}{2}(P_3 + C_3), X_0 + X_4\rangle$,

$J_1 = \left(x_1^2 + x_2^2 + x_3^2 + x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = x_1u_1 + x_2u_2 + x_3u_3 + x_4u_4,$
$J_4 = x_1u_2 - x_2u_1 + x_4u_3 - x_3u_4, \quad J_5 = x_2u_3 + x_4u_1 - x_1u_4 - x_3u_2, \quad J_6 = u_0,$
$J_7 = u_1^2 + u_2^2 + u_3^2 + u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_1^2 + x_2^2 + x_3^2 + x_4^2\right)^{1/2};$
$F\left(\omega, \varphi, \omega\varphi', 0, 0, 0, \left(\varphi'\right)^2\right) = 0;$

9. $\langle G, L_1, L_2, L_3, X_4\rangle$,

$J_1 = \left(x_1^2 + x_2^2 + x_3^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = (x_0 + x_4)(u_0 + u_4), \quad J_4 = x_1u_1 + x_2u_2 + x_3u_3,$
$J_5 = u_0^2 - u_4^2, \quad J_6 = u_1^2 + u_2^2 + u_3^2; \quad u = \varphi(\omega), \quad \omega = \left(x_1^2 + x_2^2 + x_3^2\right)^{1/2};$
$F\left(\omega, \varphi, 0, \omega\varphi', 0, \left(\varphi'\right)^2\right) = 0;$

10. $\langle G, P_3, C_3, X_1, X_2\rangle$,

$J_1 = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = x_0u_0 + x_3u_3 + x_4u_4, \quad J_4 = u_1, \quad J_5 = u_2,$

$$J_6 = u_0^2 - u_3^2 - u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2}; \quad F\left(\omega, \varphi, \omega\varphi', 0, 0, \left(\varphi'\right)^2\right) = 0;$$

11. $\langle L_1, L_2, L_3, P_1 + C_1, P_2 + C_2, P_3 + C_3, X_0 + X_4\rangle$,

$$J_1 = \left(x_1^2 + x_2^2 + x_3^2 + x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = x_1u_1 + x_2u_2 + x_3u_3 + x_4u_4, \quad J_4 = u_0,$$
$$J_5 = u_1^2 + u_2^2 + u_3^2 + u_4^2; \quad u = \varphi(\omega), \quad \omega = \left(x_1^2 + x_2^2 + x_3^2 + x_4^2\right)^{1/2};$$
$$F\left(\omega, \varphi, \omega\varphi', 0, \left(\varphi'\right)^2\right) = 0;$$

12. $\langle G, P_3, C_3, L_3, X_1, X_2\rangle$,

$$J_1 = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2}, \quad J_2 = u, \quad J_3 = x_0u_0 + x_3u_3 + x_4u_4, \quad J_4 = u_1^2 + u_2^2,$$
$$J_5 = u_0^2 - u_3^2 - u_4^2\,; \quad u = \varphi(\omega), \quad \omega = \left(x_0^2 - x_3^2 - x_4^2\right)^{1/2}; \quad F\left(\omega, \varphi, \omega\varphi', 0, \left(\varphi'\right)^2\right) = 0;$$

13. $\langle G, L_1, L_2, L_3, P_1, P_2, P_3\rangle$,

$$J_1 = (x_0^2 - x_1^2 - x_2^2 - x_3^2 - x_4^2)^{1/2}, \quad J_2 = u, \quad J_3 = \frac{u_0 - u_4}{x_0 + x_4},$$
$$J_4 = x_0u_0 + x_1u_1 + x_2u_2 + x_3u_3 + x_4u_4, \quad J_5 = u_0^2 - u_1^2 - u_2^2 - u_3^2 - u_4^2;$$
$$u = \varphi(\omega), \quad \omega = (x_0^2 - x_1^2 - x_2^2 - x_3^2 - x_4^2)^{1/2}; \quad F\left(\omega, \varphi, \frac{\varphi'}{\omega}, \omega\varphi', \left(\varphi'\right)^2\right) = 0.$$

Symmetry of Stochastic Equations

Giuseppe GAETA

Dipartimento di Matematica, Università di Milano, v. Saldini 50, I–20133 Milano, Italy
E-mail: *gaeta@mat.unimi.it*

We discuss symmetries of Ito equations, and the relations of these with symmetries of the associated Fokker–Planck equation.

Symmetry methods are by now recognized as one of the main tools to attack *deterministic* differential equations (both ODEs and PDEs); see e.g. [3, 8, 15, 20, 21, 24, 25]. The situation is quite different for what concerns *stochastic* differential equations [1,12,13,16,19]: here, symmetry considerations are of course quite widely used by theoretical physicists (see e.g. [4, 14, 17] in the context of KPZ theory), but a rigorous and general theory comparable to the one developed for deterministic equation is still lacking, and the attention of the community working on symmetry methods should maybe be called to this.

We would like to quote here early work by Misawa [18], mainly concerned with conservation laws for stochastic systems, and later on the work by Arnold and Imkeller [1,2] for normal forms of stochastic equations.

In the following I will report on some work I have done – to a large extent in collaboration with N. Rodríguez Quintero – on symmetries of stochastic (Ito) equations, and how these compare with the symmetries of the associated diffusion (Fokker–Planck) equations [5, 7, 22, 23]; further details can be found in [9, 11].

It should be stressed that in this note an Ito equation will be seen as describing a one-particle stochastic process only. The same equation does also describe N-particles processes, or a random dynamical system [1], and in this case there will be further symmetries beyond those admitted in the frame of the one-particle processes interpretation, as discussed in [9].

1 Projectable symmetries

We assume the reader to be fairly familiar with the concept of symmetry of a deterministic differential equation, and the methods to characterize these; so we will just recall some formula of use in the following, mainly to fix notation, identify the class of transformations we are going to consider, and compare with the situation for stochastic equations.

Let us first consider the case of systems of first order ODEs in $\mathbb{R}^n$,

$$\dot{x}^i - f^i(x,t) = 0. \tag{1}$$

The general form of Lie-point vector fields is in this case, writing $\partial_i = \partial/\partial x^i$, $X = \tau(x,t)\partial_t + \xi^i(x,t)\partial_i$. Such a vector field, however, is somehow too general: indeed, we would like the change on t not to depend on the value assumed by the solution $x(t)$; this is particularly relevant when we think of the ODE as describing not the motion of a single particle in $\mathbb{R}^n$, but that of an assembly of particles. We would thus like to keep the special role of time, i.e. require $\tau = \tau(t)$; in other words, we will consider

$$X_0 = \tau(t)\partial_t + \xi^i(x,t)\partial_i. \tag{2}$$

A similar discussion holds for symmetries of PDEs, first or higher order. Here we will deal only with scalar PDEs, i.e. equations for a single dependent variable $u = u(x,t)$. In this case

we would write in general $X = \tau(x,t,u)\partial_t + \xi^i(x,t,u)\partial_i + \phi(x,t,u)\partial_u$. On physical terms, it is preferable to consider only transformations such that the independent variables are transformed independently of the values assumed by the dependent ones, i.e. such that τ and the ξ^i do not depend on u; also, here we are primarily interested in evolution equations, and in order to guarantee that the time keeps its distinguished role we should also ask that τ does not depend on x. Thus, in the end we want to consider transformations of the form

$$X = \tau(t)\frac{\partial}{\partial t} + \xi^i(x,t)\frac{\partial}{\partial x^i} + \phi(x,t,u)\frac{\partial}{\partial u}. \tag{3}$$

Definition 1. The vector fields – and in particular symmetry generators – of the form (2), (3) will be called "fiber-preserving", or simply **projectable**.

Let us now consider in particular a system of ODEs, which we write in the form (1). The determining equations for the symmetry generators of this are easily determined (these should be compared to the determining equations for stochastic differential equations discussed in the next section). We will use, here and below, the notation

$$\{f,\xi\}^i := \ (f^j \cdot \partial_j)\xi^i - (\xi^j \cdot \partial_j)f^i. \tag{4}$$

Lemma 1. *The projectable symmetries of* (2) *are given by vector fields* X_0 *as above with coefficients satisfying*

$$\partial_t(\xi^i - \tau f^i) + \{f,\xi\}^i = 0. \tag{5}$$

For given functions $f^i(x,t)$ the partial differential equations (5) always [20, 24] have non-trivial solutions $\tau(t)$ and $\xi^i(x,t)$; for example we can fix $\tau(t)$ and compute $\xi^i(x,t)$. Although an infinite number of symmetries of (5) exist, in general there is no constructive way to find them.

For further detail on symmetries of (deterministic) ODEs and PDEs, and applications, the reader is referred to [3, 8, 15, 20, 21, 24, 25].

2 Stochastic differential equations

Let us turn to stochastic equations [1, 6, 12, 13, 16, 19], and let us consider an Ito equation[1]

$$dx^i = f^i(x,t)\,dt + \sigma^i_k(x,t)\,dw^k, \tag{6}$$

where f and σ are smooth functions, $\sigma(x,t)$ is a nonzero matrix and the w^k are independent homogeneous standard Wiener processes, so that

$$\langle |w^i(t) - w^j(s)|^2 \rangle = \delta^{ij}(t-s).$$

The equation (6) should be seen as a map from the vector Wiener process $\boldsymbol{w}(t) = \{w^1(t), \ldots, w^n(t)\}$ to the stochastic process undergone by $\{x^1(t), \ldots, x^n(t)\}$, and its meaning is precisely that of defining the vector stochastic process $\boldsymbol{x}(t)$.

If we consider a function $y = \Phi(x)$, its evolution under the Ito equation (6) is described (again in terms of a stochastic equation) by the *Ito formula*:

$$\begin{aligned} dy^i &= \frac{\partial \Phi^i}{\partial x^j}\,dx^j + \frac{1}{2}\frac{\partial^2 \Phi^i}{\partial x^j \partial x^k}\,dx^j dx^k \\ &= \left[f^j \partial_j \Phi^i + (1/2)\partial^2_{jm}\Phi^i(\sigma\sigma^T)^{jm}\right]dt + \left[(\partial_j \Phi^i)\sigma^{jk}\right]dw^k. \end{aligned} \tag{7}$$

[1] It is well known that any Ito equation is equivalent to a Stratonovich equation; for the Ito equation (6), the associated Stratonovich equation is $dx^i = b^i(x,t)dt + \sigma^i_k(x,t) \circ dw^k$, with $b^i = f^i - (1/2)[\sigma(\partial\sigma^T/\partial x))]$. We will stick to the Ito formulation in all of this note.

The Fokker–Planck equation

$$\partial_t u = -\partial_i \left(f^i u\right) + \frac{1}{2}\,\partial^2_{ij}\left[(\sigma\sigma^T)^{ij} u\right] \tag{8}$$

is associated to the Ito equation (6) and describes the evolution of the probability measure $\rho = u(x,t)$ under the stochastic process described by (6). Equations (6) and (8) contain the same *statistical* information [1, 12, 13, 16, 19] as far as one-particle processes are concerned (but not if we think of the Ito equation as describing a random dynamical system, see [1,9]), provided σ satisfies the **non-degeneracy condition**

$$A := \frac{1}{2}\sigma\,\sigma^T \neq 0$$

which we will assume throughout this note.

We stress that we are interested in equation (8) as far as it describes the time evolution of the probability measure $\rho = u(x,t)$ under the stochastic process (6). It is obvious that for this interpretation $u(x,t)$ should be non-negative and subject to the condition

$$\int_{-\infty}^{+\infty} u(x,t)\, dx^1 \cdots dx^n = 1. \tag{9}$$

This is relevant in connection with the allowed transformations in the $(x,t;u)$ space: only transformations preserving this normalization do represent symmetries of the Fokker–Planck equation compatible with its probabilistic interpretation[2], and one should expect a correspondence between symmetries of the Ito equation and this subclass – rather than all – of the symmetries of the Fokker–Planck equation.

Another simple but relevant point which should be stressed is the following: different Ito equations which have the same f but different matrices σ can provide the same term $\sigma\sigma^T$ and thus the same Fokker–Planck equation.

A simple example is provided e.g. by σ orthogonal: in this case we have by definition $\sigma\sigma^T = I$, so that all the Ito equations with the same f and any orthogonal matrix σ give the same Fokker–Planck equation[3]. Similarly, σ and $\widetilde{\sigma} = \sigma B$, with B any orthogonal matrix, will give the same Fokker–Planck equation (and conversely σ and $\widetilde{\sigma}$ give the same Fokker–Planck – with the same f – only if there is an orthogonal matrix B such that the above relation is satisfied.

Thus if we consider a continuous variation of σ, say $\sigma + \varepsilon\gamma$, in the Ito equation, the associated Fokker–Planck equation remains unchanged provided $(\sigma+\varepsilon\gamma)(\sigma+\varepsilon\gamma)^T = \sigma\sigma^T$, which at order ε is simply

$$\sigma\gamma^T + \gamma\sigma^T = 0. \tag{10}$$

3 Symmetries of stochastic ODEs

3.1 Spatial symmetries

We will at first consider symmetries not acting on the time variable t, i.e. $X_0 = \xi^i(x,t)\partial_i$. Thus, we consider a near-identity change of coordinates, passing from x to y via

$$x^i \to y^i = x^i + \varepsilon\xi^i(x,t). \tag{11}$$

[2] In other words, we should set the FP equation in the function space $\mathcal{F}$ defined by (9), and thus accept only transformations mapping $\mathcal{F}$ to itself.

[3] The one-point stochastic processes described by two different Ito equations having the same associated Fokker–Planck equation have the same statistical properties (the probability measures evolve in the same way), but *are* different: the same realization of the Wiener process $\boldsymbol{w}(t)$ leads to different sample paths.

Using the Ito formula, we easily check that at first order in ε, this transformation maps the Ito equation (6) into a new Ito equation

$$dy^i = \widetilde{f}^i(y,t)\,dt + \widetilde{\sigma}^i_k(y,t)dw^k, \tag{12}$$

where we have explicitly

$$\begin{aligned}\widetilde{f}^i &= f^i + \varepsilon\,[\partial_t\xi^i + f^j\partial_j\xi^i - \xi^j\partial_j f^i + (1/2)(\sigma\sigma^T)^{jk}\partial^2_{jk}\xi^i],\\ \widetilde{\sigma}^i_k &= \sigma^i_k + \varepsilon\,[\sigma^j_k\partial_j\xi^i - \xi^j\partial_j\sigma^i_k].\end{aligned} \tag{13}$$

When (11) maps (6) into itself, i.e. when (12) coincides with (6) [up to terms $o(\varepsilon)$], we say that $X_0 = \xi^i(x,t)\partial_i$ is a (Lie-point) spatial **symmetry** of (6). Thus, Lie-point spatial symmetries of (6) are identified by the vanishing of terms $O(\varepsilon)$ in (13). In the following statement, we use the notations introduced above for A and $\{\cdot,\cdot\}$.

Proposition 1. *The (generators of) Lie-point spatial symmetries of the Ito equation* (6) *are given by vector fields $X_0 = \xi^i(x,t)\partial^i_x$ with coefficients ξ^i satisfying the* determining equations for spatial symmetries *of an Ito equation:*

$$\begin{aligned}&\partial_t\xi^i + \{f,\xi\}^i + (1/2)(\sigma\sigma^T)^{jk}\partial^2_{jk}\xi^i = 0,\\ &\{\sigma_k,\xi\}^i = 0.\end{aligned} \tag{14}$$

These are $n + n^2$ equations for the $n+1$ functions ξ^i, τ; thus for $n > 1$ they have some solution only in very exceptional cases. This should not be surprising, as symmetry is a non-generic property.

Note that if $\sigma = \sigma(t)$ does not depend on the spatial variables, the second equation of (14) reduces to $\sigma^j_k\partial_j\xi^i = 0$, which in turns implies vanishing of the term $(\sigma\sigma^T)^{jk}\partial^2_{jk}\xi^i$, which in this case can be rewritten as $\sigma^k_p\partial_k(\sigma^j_p\partial_j\xi^i)$. Thus, (14) are in this case equivalent to the determining equations for symmetries of the deterministic part of the Ito equation [see (5) and recall now we are assuming $\tau = 0$] with the additional condition $\sigma^j_k\partial_j\xi^i = 0$.

3.2 Spatio-temporal symmetries

We could of course consider transformations acting also on t: in this case the t transformation would also affect the processes $w(t)$, and some extra care should be paid. We will not go over the details (which consist in studying how $w(t)$ is changed and include this in the change undergone by σ), and just report the result obtained in [11], with the same notation as above.

Proposition 2. *The projectable vector field $X_0 = \tau(t)\partial_t + \xi^i(x,t)\partial^i_x$ is a symmetry generator for the Ito equation* (6) *if and only if the coefficients $\{\tau,\xi\}^i$ satisfy the* full determining equations *for projectable symmetries of an Ito equation:*

$$\begin{aligned}&\partial_t\left(\xi^i - \tau f^i\right) + \{f,\xi\}^i - A^{jk}\partial^2_{jk}\xi^i = 0,\\ &\{\sigma_k,\xi\}^i - \tau\partial_t\sigma^i_k - (1/2)\sigma^i_k\partial_t\tau = 0.\end{aligned} \tag{15}$$

Note that the symmetries which are linear in x, i.e. such that $\xi^i(t;\boldsymbol{x}) = M^i_j(t)x^j$, are given by the same equations as for symmetries of the deterministic part of the Ito equation (6), i.e. (5), plus the additional condition $M^i_j\sigma^j_k = M^j_p x^p\partial_j\sigma^i_k + \tau\partial_t\sigma^i_k + (1/2)\sigma^i_k\partial_t\tau$.

A relevant case in applications is the one where $f^i = f^i(\boldsymbol{x})$ and $\sigma^i_k = \sigma^i_k(t)$ or even $\sigma^i_k = \text{const} = S^i_k$; this correspond to an autonomous dynamical system subject to a noise which depends only on t or even a constant noise. In this case (14) can be discussed quite completely. Indeed, with σ independent of the spatial coordinates, the second of these reads $2\sigma^j_k\partial_j\xi^i =$

$2\tau\partial_t\sigma^i_k + \sigma^i_k\partial_t\tau$. As the r.h.s. depends only on t, by differentiating with respect to x^m we get the equation $\sigma^j_k(\partial^2\xi^i/\partial x^j\partial x^m) = 0$: i.e., the (symmetric) matrix of second derivatives of ξ^i, H^i_{jm} must be such that $\sigma H^i = H^i\sigma = 0$. Notice that in particular, if $\sigma^i_k(t) = \lambda_{(i)}(t)\delta^i_k$ with all $\lambda_{(i)} \not\equiv 0$ (or however if σ^{-1} exists), this means that ξ can be at most linear in the x.

4 Symmetries of the Fokker–Planck equation

We will now discuss the determining equations for projectable symmetry generators of the Fokker–Planck equation (8) in arbitrary spatial dimensions; general symmetries of the Fokker–Planck equations (with some limitations on σ) in one and two space dimensions have been completely classified [5, 7, 23].

It will be convenient to rewrite the Fokker–Planck equation as

$$u_t + A^{ij}\,\partial^2_{ij}u + B^i\,\partial_i u + Cu = 0; \tag{16}$$

the coefficients A, B, C depend on x and t only and are given explicitly by[4]

$$A = -(1/2)\sigma\sigma^T, \qquad B^i = f^i + 2\partial_j A^{ij}, \qquad C(x,t) = (\partial_i \cdot f^i) + \partial^2_{ij}A^{ij}. \tag{17}$$

We consider a projectable vector field of the form (3). Computing the second prolongation of this and applying it to the equation, we obtain the determining equations for symmetries of the Fokker–Planck equation.

It follows by general results on Lie-point symmetries of linear equations [8, 20], or by an elementary explicit computation, that:

Lemma 2. *The projectable symmetries of the Fokker–Planck equation* (16) *are given by vector fields in the form* (8) *with* $\phi = \alpha(x,t) + \beta(x,t)u$.

Again by linearity, we will have "trivial" symmetries $X_\alpha = \alpha(x,t)\partial_u$, with $\alpha(x,t)$ an arbitrary solution to the FP equation itself; this is just expressing the linear superposition principle [20]. Note that in order to preserve the normalization (9), we should moreover require $\int \alpha(x,t)dx = 0$, which rules out nontrivial non-negative solutions.

We will thus from now on focus on other, i.e. "nontrivial", symmetries only, and take $\alpha(x,t) = 0$.

Proposition 3. *The nontrivial projectable symmetries of the Fokker–Planck equation* (16) *are given by vector fields in the form* (3) *with* $\phi = \beta(x,t)u$, *where* τ, ξ^i, β *satisfy the* determining equations

$$\begin{aligned}
&\partial_t(\tau A^{ik}) + (\xi^m\partial_m A^{ik} - A^{im}\partial_m\xi^k - A^{mk}\partial_m\xi^i) = 0,\\
&\partial_t(\tau B^i) - \left[\xi^i_t + B^m\partial_m\xi^i - \xi^m\partial_m B^i\right] + (A^{ik}\partial_k\beta + A^{mi}\partial_m\beta) - A^{mk}\partial^2_{mk}\xi^i = 0,\\
&\partial_t(\tau C) + \beta_t + A^{ik}\partial^2_{ik}\beta + B^i\partial_i\beta + \xi^m\partial_m C = 0.
\end{aligned} \tag{18}$$

It should be stressed that in the computations leading to (18) we have not required preservation of the normalization $\int u\,dx = 1$; when we require this, it turns out that

Lemma 3. *The nontrivial projectable symmetries of the Fokker–Planck equation* (16), *in the form* (3) *with* $\phi = \beta(x,t)u$, *preserve the normalization* (9) *if and only if*

$$\beta = -\mathrm{div}(\xi). \tag{19}$$

[4] Recall that our non-degeneracy assumption guarantees $A \neq 0$.

In other words, this lemma guarantees that if we are looking for the (nontrivial) symmetries of a Fokker–Planck equation compatible with its probabilistic interpretation, we do not have to deal with the general form (3) of the symmetry vector field, but we can use instead the ansatz

$$X = \tau(t)\partial_t + \xi^i(x,t)\partial_i - [\mathrm{div}(\xi)u]\partial_u; \tag{20}$$

this substantially simplifies the analysis of symmetries.

5 Symmetries of the Ito versus symmetries of the associated FP equation

We are specially interested in discussing how the symmetries of the partial differential equation (16) and those of the symmetries of the system of stochastic ODEs (6) are related.

In order to do this, we should express the coefficients A, B, C in terms of f and σ; indeed $A = -(1/2)\sigma\sigma^T$, $B^i = f^i + 2\partial_k A^{ik}$, and $C = \partial_i f^i + \partial^2_{ik} A^{ik}$. With the latter two of these and with some manipulations, see [11], (18) reads

$$\begin{aligned}
&\partial_t(\tau A^{ik}) + \left(\xi^m \partial_m A^{ik} - A^{im}\partial_m \xi^k - A^{km}\partial_m \xi^i\right) = 0,\\
&\left[\partial_t(\xi^i - \tau f^i) + \{f,\xi\}^i - A^{mk}\partial^2_{mk}\xi^i\right] - 2\left[A^{ik}\partial_k\beta + \ A^{im}\partial^2_{mk}\xi^k\right] = 0,\\
&\left[\partial_t + f^i\partial_i - A^{ik}\partial^2_{ik}\right][\beta + \partial_m\xi^m] = 0.
\end{aligned} \tag{21}$$

It is convenient to introduce the shorthand notations

$$\begin{aligned}
&\Gamma^k_j = \sigma^m_j\partial_m\xi^k - \xi^m\partial_m\sigma^k_j - \tau\partial_t\sigma^k_j - (1/2)\sigma^k_j\partial_t\tau,\\
&\Lambda^i = -\left[\partial_t(\xi^i - \tau f^i) + \{f,\xi\}^i - A^{mk}\partial^2_{mk}\xi^i\right].
\end{aligned} \tag{22}$$

With these, (21) is rewritten as

$$\begin{aligned}
&\sigma^i_j\Gamma^k_s\delta^{js} + \sigma^k_j\Gamma^i_s\delta^{js} = 0,\\
&\Lambda^i + 2\left[A^{ik}\partial_k\beta + \ A^{im}\partial^2_{mk}\xi^k\right] = 0,\\
&\left[\partial_t + f^i\partial_i - A^{ik}\partial^2_{ik}\right][\beta + \partial_m\xi^m] = 0.
\end{aligned} \tag{23}$$

It should be stressed that with the notation just introduced, the determining equations (15) for symmetries of the Ito equation (6) read simply

$$\Lambda^i = 0, \qquad \Gamma^i_j = 0. \tag{24}$$

With this notation, the comparison of symmetries for the Ito and the associated Fokker–Planck equation is quite a simple matter.

5.1 From the Ito to the FP symmetries

We will first investigate if symmetries of an Ito equation result in symmetries of the associated Fokker–Planck equation.

We first note that for $\Gamma = 0$, the first of (23) is satisfied. As for the second of (23), when $\Lambda^i = 0$ this reduces to

$$A^{ik}\partial_k\beta = -A^{im}\partial^2_{mk}\xi^k. \tag{25}$$

Obviously β is not present in symmetries of the Ito equation, so we can choose it as to satisfy the third of (23) and (25): for this it suffices to choose

$$\beta = -\partial_m \xi^m + c_0 = -\mathrm{div}(\xi) + c_0. \tag{26}$$

We know from Lemma 2 that actually we have to take $c_0 = 0$, and that this is actually the only choice of β providing us with a normalization-preserving symmetry of the FP. Our findings are summarized as follows:

Proposition 4. *Let $X_0 = \tau\partial_t + \xi^i\partial_i$ be a symmetry of the Ito equation* (6)*. Then X_0 extends to a unique normalization preserving symmetry $X := X_0 - [(\mathrm{div}\xi)u]\partial_u$ of the associated Fokker–Planck equation.*

5.2 From the FP to the Ito symmetries

Let us now consider the converse question, i.e. if and when a symmetry of the FP equation associated to an Ito equation can be projected to a symmetry of the Ito equation itself.

As the probabilistic interpretation of the FP requires the normalization condition (9), we expect only symmetries identified by Lemma 3 can provide symmetries of related Ito equations.

Moreover, as recalled above, there are transformations which map an Ito equation into a different one with the same statistical properties and thus the same associated FP equation: these would be symmetries of the FP but not of the Ito equation. Thus, not all the symmetries of the FP should be expected to produce symmetries of the Ito equation.

By Lemma 3, we assume $\beta = -\mathrm{div}(\xi)$; this guarantees that the third of (23) holds, and also that the second of (23) reduces to $\Lambda^i = 0$. Hence we only have to discuss the relation between the first of (23) and the second of (24). These two equations can be rewritten, respectively, as

$$\sigma\Gamma^T + \Gamma\sigma^T = 0 \qquad \text{and} \qquad \Gamma = 0. \tag{27}$$

The second of these implies the first, but the converse is not true: hence there is *not* a complete equivalence.

This just corresponds to a given FP equation corresponding to different Ito equations: the transformations with $\Gamma \neq 0$ but $\sigma\Gamma^T + \Gamma\sigma^T = 0$ will be precisely those which map an Ito equation E_0 into a different Ito equation E_1 which has the *same* Fokker–Planck associated equation, see (10).

Proposition 5. *Let $X = \tau(t)\partial_t + \xi^i(x,t)\partial_i - [(\mathrm{div}\xi)u]\partial_u$ be a symmetry of the Fokker–Planck equation associated to the Ito equation* (6)*. Then X maps the Ito equation into a (generally, different) Ito equation with the same statistical properties; X is a symmetry of the Ito equation* (6) *if and only if Γ defined in* (22) *satisfies $\Gamma^i_k = 0$.*

We may note that from the above system (24), restricting to the case where $f(t,x) = f(x)$ and $\sigma(t,x) = \sigma(x)$, we recover the results of Cicogna and Vitali [5] for the one-dimensional setting. From (22) it is also possible to recover the results of Shtelen and Stogny [23] for the two-dimensional Kramers equation, as well as the results of Finkel [7] for certain two-dimensional FP equations.

5.3 Examples

Example 1. As the first example, we consider the case $f(t,x) = 0$, $\sigma(t,x) = \sigma_0 = \mathrm{const} \neq 0$, i.e. the equation

$$dx = \sigma_0\, dw(t) \tag{28}$$

which represents a free particle subject to constant noise. The corresponding Fokker–Planck equation is simply the heat equation $u_t = (\sigma_0^2/2)u_{xx}$. The symmetries of the heat equation (other than the trivial ones $v_\alpha = \alpha(x,t)\partial_u$ with $\alpha_t = \alpha_{xx}$) are well-known to be [20, 24]

$$v_1 = \partial_t, \qquad v_2 = \partial_x, \qquad v_3 = u\partial_u, \qquad v_4 = \sigma_0^2 t\partial_x - \sigma_0 xu\partial_u,$$
$$v_5 = 2t\partial_t + x\partial_x, \qquad v_6 = t^2\partial_t + xt\partial_x - (1/2)(t + x^2/\sigma_0^2)u\partial_u.$$

Of these, v_1, v_2 and v_5 (which do not act on u) are also symmetries of the Ito equation (28), as is easily checked using (14). Notice that (19) is satisfied for these, and is not satisfied for v_3, v_4 and v_6. The vector fields v_1, v_2 and v_5 do actually span the symmetry algebra of (28).

Example 2. As an example in two space dimensions [with coordinates $(x_1, x_2) = (x, y)$], we choose

$$dx = y\,dt,$$
$$dy = -k^2 y\,dt + \sqrt{2k^2}\,dw(t) \tag{29}$$

with k^2 a positive constant.

The corresponding Fokker–Planck equation is the Kramers equation

$$u_t = k^2 u_{yy} - yu_x + k^2 yu_y + k^2 u; \tag{30}$$

the symmetries of this were studied in [23] and, apart from the trivial ones v_α, are

$$v_1 = \partial_t, \qquad v_2 = \partial_x, \qquad v_3 = e^{-k^2 t}\,[k^{-2}\partial_x - \partial_y], \qquad v_4 = u\partial_u,$$
$$v_5 = t\partial_x + \partial_y - (1/2)(y + k^2 x)u\partial_u, \qquad v_6 = e^{k^2 t}\,[k^{-2}\partial_x + \partial_y - yu\partial_u].$$

Here v_1, v_2 and v_3 satisfy (19), while for v_4, v_5 and v_6 this is violated. According to our definition, the symmetries of the equations (29) are again v_1, v_2 and v_3, as easily checked.

Example 3. We consider now an example where the correspondence between normalization-preserving symmetries of the FP equation and symmetries of the Ito equation is not complete, i.e. the two-dimensional Ito system (with zero drift)

$$dx^1 = \cos(t)dw^1 - \sin(t)dw^2,$$
$$dx^2 = \sin(t)dw^1 + \cos(t)dw^2; \tag{31}$$

the corresponding Fokker–Planck equation is now just the two dimensional heat equation $u_t = (1/2)\triangle u$.

It is now immediate to check that the vector field $X_0 = \partial_t$ is a symmetry of the FP equation, but *not* a symmetry of (31). Obviously, the case of any orthogonal σ with $\partial_t \sigma_k^i \not\equiv 0$ will be exactly the same.

Example 4. Consider n uncoupled equations for equal "Langevin harmonic oscillators" subject to independent stochastic noises [16, 22]; this system is described by the Ito system

$$dx^i = -x^i\,dt + \sqrt{2s_i}\,dw^i, \qquad i = 1, 2, \ldots, n \tag{32}$$

(no sum on i) where we assume all the s_i are strictly positive; the corresponding Fokker–Planck equation is

$$\partial_t u = \sum_{i=1}^{n} [s_i \partial_{ii}^2 u + x^i \partial_i u + u].$$

In this case we get the symmetries ($i = 1, 2, \dots, n$)

$$v_1 = \partial_t, \qquad v_2 = e^{-2t}\left[\partial_t - \sum_{i=1}^{n} x^i \partial_i + nu\partial_u\right], \qquad v_{q_i} = e^{-t}\partial_i.$$

Example 5. Finally, we consider now the n-dimensional nonlinear case

$$dx^i = -(1 - \lambda\|x\|^2)x^i\, dt + dw^i, \tag{33}$$

where $\|x\|$ is the norm of the vector $\boldsymbol{x}$ and $\lambda \neq 0$. By inserting $f^i = -x^i(1-\lambda\|x\|^2)$ and $\sigma^i_j = \delta_{ij}$ in (24) we obtain, from the second of these, $\xi^i = h^i(t) + (\tau_t/2)x^i$. Inserting this into the first of (24) and isolating the coefficients of different powers of x, we get that the only symmetry is given by $v = \partial_t$.

Note that we got no rotation symmetry; this is because within the class of transformations we are considering we can rotate the vector x, but *not* the vector Wiener process $w(t)$; transformations allowing to rotate $w(t)$ as well will be considered in the next section.

6 W-symmetries

We will now consider symmetries involving not only the spatial and time variables (x, t), but also the vector Wiener processes $w(t)$ entering in the n-dimensional Ito equation (6). We will specifically consider infinitesimal transformations of the form

$$\begin{aligned} &x^i \to y^i = x^i + \varepsilon\xi^i(x,t), \\ &t \to s = t + \varepsilon\tau(t), \\ &w^i \to z^i = w^i + \varepsilon\mu^i(w,t). \end{aligned} \tag{34}$$

We also call symmetry generators of this form, "*W-symmetries*".

Note that this is not the most general possible form of a transformation for the variables involved in (1); some words on this restriction are in order here.

The restriction on τ and ξ is the same as considered above. Moreover, we only allow "internal" transformations of w, i.e. they cannot depend on $x(t)$. As we think of the stochastic process $w(t)$ to be independent of the evolution of the $x(t)$, we like its transformation not to depend on the latter. Finally, we have allowed the transformation on the spatial coordinates $x(t)$ to depend on x and t, but not on the w; this means that we do not want to consider transformations of the spatial coordinates which depend on the realization of the stochastic process $w(t)$. This again is somewhat a natural requirement in physical terms[5].

In order to compute how (34) acts on the Ito equation (6), we use the Ito formula (7). Moreover, due to the form of (34), we can adopt a "two-steps procedure", see [9]: the transformations of the (x, t) variables and of the stochastic process $w(t)$ do not interfere with each other. It turns out that some strong limitation on the functions μ^i arise.

Lemma 4. *The infinitesimal transformation $w \to z = w + \varepsilon\mu(w, t)$ maps the vector Wiener process $w(t)$ into a vector Wiener process $z(t)$ if and only if $\mu = Bw$, with B a real antisymmetric matrix. Equivalently, if and only if $z = Mw$ with M orthogonal.*

Note that as B is antisymmetric matrix, it vanishes in dimension one: for one-dimensional Ito equations we have no new symmetries with respect to those discussed above.

[5]It should be however stressed that in this way we are also discarding the transformations needed to obtain *normal forms* of stochastic differential equations, see [1, 2] and references therein.

Proposition 6. *Under the infinitesimal transformation* (34)*, with B a real antisymmetric matrix, the Ito equation* (6) *is changed into a (generally, different) Ito equation. The Ito equation* (6) *is invariant under* (34) *if and only if τ, ξ, μ satisfy the determining equations for W-symmetries:*

$$\partial_t \xi^i + \{f, \xi\}^i - \partial_t(\tau f^i) + A^{jk}\partial^2_{jk}\xi^i = 0,$$
$$\{\sigma_k, \xi\}^i - \tau\partial_t\sigma^i_k - (1/2)(\partial_t\tau)\sigma^i_k - \sigma^i_p B^p_k = 0. \tag{35}$$

If we just consider a transformation $w \to z = Mw$, with M orthogonal as required by Lemma 4, the Fokker–Planck equations associated to the Ito equation and to the transformed one will be the same. Thus all the discussion conducted in Section 5 about the relations betwen symmetries of an Ito equation and of the associated FP equation also applies to transformations of the form (34)[6].

Example 6. Let us consider again the two-dimensional Ito equation (29). If we look at the second set of determining equations and single out the one for $i = 2$ and $k = 1$, we have immediately that $B = 0$, i.e. in this case we have no new symmetry by allowing transformation of w.

Example 7. Let us consider again the two-dimensional Ito system (31) We will write $\xi^1 = \alpha$, $\xi^2 = \beta$, and $B_{12} = -B_{21} = b$. The most general solution to the determining equations turns out to be

$$\alpha = [\tau_t/2 - \sin(2t)\tau]x + [b + \cos(2t)\tau]y + \alpha_0(t),$$
$$\beta = -[b + \tau]x + [\tau_t/2]y + \beta_0(t).$$

By setting $\tau = \alpha_0 = \beta_0 = 0$, we obtain a new symmetry, corresponding to $\alpha = by$ and $\beta = -bx$ with b arbitrary, i.e. given by

$$X = \left(y\frac{\partial}{\partial x} - x\frac{\partial}{\partial y}\right) + \left(w^2\frac{\partial}{\partial w^1} - w^1\frac{\partial}{\partial w^2}\right).$$

Note this is nothing else than a simultaneous (and identical) rotation in the (x, y) and in the (w_1, w_2) planes.

Example 8. We will now consider again the case of n uncoupled equal "Langevin harmonic oscillators", see (32) above.

If we discard symmetries with $B = 0$ (i.e. those obtained above), we are still left with a nontrivial possibility, i.e. B an arbitrary (real, antisymmetric) constant matrix and $\xi^i = C^i{}_k x^k$, where $C^i{}_k = (s_i/s_k)B^i_k$ (no sum on i, k here).

The meaning of this result is obvious: we can act on this system by an arbitrary $SO(n)$ rotation in the w space and a related rotation in the x space.

If we assume $s_1 = s_2 = \cdots = s_n = s$, we have indeed $C = B$ and the rotations in w and x spaces do just coincide. For general $s_1, \ldots, s_n$, the (s_i/s_k) factors relating the C and B matrices are also easily understood: we could rescale each of the x^i by a factor $\sqrt{2s_i}$, $x^i = \sqrt{2s_i}y^i$ (no sum on i), arriving at the manifestly rotationally invariant n-dimensional Ito equation $dy^i = -y^i dt + dw^i$.

Example 9. Let us consider again (33). We easily check that it is rotationally invariant with a W-symmetry: take $\tau = 0$ and $\xi^i = B^i_k x^k$, so that

$$\{\xi, f\}^i = \{Bx, (1 - \lambda||x||^2)x\} = -2\lambda x^i\left(x^j B^j_k x^k\right) = 0,$$

the last equality following from $B = -B^T$. That is, (33) is indeed symmetric under simultaneous identical rotations of the x and w vectors.

[6]Needless to say, for more general transformations, for which the transformations of the (x, t) variables and of the vector Wiener process $w(t)$ do interfere with each other, this would not be the case.

7 Discrete symmetries

We will now briefly consider, for the sake of completeness, *discrete* symmetries of stochastic differential equations. Similarly to what happens in the deterministic case (see e.g. [10]), the resulting determining equations are in general too difficult to be attacked except for very simple classes of transformations (e.g. reflections, or however linear ones). On the other side, they can be used to check if a given discrete transformation is a symmetry of a given stochastic differential equation; and/or to determine the stochastic differential equations which admit a given discrete transformation as a symmetry.

We consider again an Ito equation of the form (6); here we will not consider transformations acting on the t coordinate, and will thus limit to consider the change of coordinates in the x and w spaces given by

$$y^i = \phi^i(x,t), \qquad w^k(t) = R^k_{\ p}(t) z^p(t). \tag{36}$$

As required by Lemma 4, we take $R \in O(n)$. We write as usual $A = -(1/2)\sigma\sigma^T$.

With the Ito formula we have at once that y obeys the Ito equation

$$dy^i = \left[\frac{\partial \phi^i}{\partial x^j} f^j - A^{jk} \frac{\partial^2 \phi^i}{\partial x^j \partial x^k} + \frac{\partial \phi^i}{\partial t} \right] dt + \left[\frac{\partial \phi^i}{\partial x^j} \sigma^j_{\ p} R^p_{\ k} \right] dz^k. \tag{37}$$

Proposition 7. *The transformation* (34) *is a symmetry of the Ito equation* (6) *if and only if* ϕ, R *satisfy the* determining equations for discrete symmetries *of an Ito equation:*

$$\begin{aligned} &\frac{\partial \phi^i(x,t)}{\partial x^j} f^j(x,t) + A^{jk}(x,t) \frac{\partial^2 \phi^i(x,t)}{\partial x^j \partial x^k} + \frac{\partial \phi^i(x,t)}{\partial t} \ = \ f^i\left(\phi(x,t),t\right), \\ &\frac{\partial \phi^i(x,t)}{\partial x^j} \sigma^j_{\ p}(x,t) R^p_{\ k} = \sigma^i_{\ k}\left(\phi(x,t),t\right). \end{aligned} \tag{38}$$

Example 10. The simplest case of discrete transformation is provided by $\phi^i(x,t) = -x^i$, $R = \pm I$. In these cases, (38) reduce to

$$f^i(x,t) = -f^i(-x,t), \qquad \sigma(x,t) = \mp\sigma(-x,t). \tag{39}$$

Example 11. For the n independent "Langevin oscillators", see (32), it is immediate to check that (39) is satisfied (for $R = -I$). More generally, (38) read now (no sum over i, sum over j when repeated)

$$a_{(j)} \frac{\partial \phi^i}{\partial x_j} - \frac{s^2_{(j)}}{2} \frac{\partial^2 \phi^i}{\partial x^j \partial x^j} = a_{(i)} \phi^i, \qquad s_{(j)} \frac{\partial \phi^i}{\partial x_j} R^j_{\ k} = s_{(i)} \delta^i_{\ k}. \tag{40}$$

Example 12. For equations with $\sigma^i_{\ k}(x,t) = s_0 \delta^i_{\ k}$ (with s_0 a real constant), the second of (38) always reduces to $(\partial \phi^i / \partial x^j) = (R^{-1})^i_{\ j}$. But this implies ϕ must be a linear function of the x, $\phi^i(x,t) = L^i_{\ j}(t) x^j$ with $L \in O(n)$ an orthogonal matrix ($L = R^{-1}$). Thus in this case we are always reduced to the simple equation $L^i_{\ j} f^j(x,t) = f^i(Lx,t)$.

Group Foliation of Euler Equations in Nonstationary Rotationally Symmetrical Case

Sergey V. GOLOVIN

Lavrentyev Institute of Hydrodynamics, 15 Lavrentyev Ave., 630090 Novosibirsk, Russia
E-mail: *sergey@hydro.nsc.ru*

Euler equations for rotationally symmetrical motions of ideal fluid are considered. Basis of differential invariants for infinite-dimensional part of admitted group is calculated. The basis is used for construction of group foliation of Euler equations. Both automorphic and resolving systems are completed to involution. The resolving part of group foliation inherits finite-dimensional part of group, admitted by Euler equations. It allows us to construct invariant and partially invariant solutions of resolving system. The original functions are restored then by means of integration of automorphic system. Example of such construction is provided.

1 Introduction

The present paper can be regarded as development of the author's previous work published in [1]. Objects of investigations are differential invariants of infinite-dimensional groups, which appear as admissible groups of continuous transformations for various hydrodynamical systems. The main goal is utilization of infinite-dimensional part of admitted groups for construction of new exact solutions and obtaining new information about the observed systems. Here we use an approach based on so-called group foliation (or group stratification) of the system of PDEs with respect to admitted group. This approach proved to be useful in several examples [2, 4–7]. Here we construct a group foliation of Euler equations describing rotationally symmetrical motions of ideal fluid. The base of group foliation is an infinite-dimensional group, which involves two arbitrary functions of time. In comparison with cited articles we observe not a single equation but a system of equations with 4 unknown functions. It causes the main complexity of present work.

Description of classical theory of differential invariants one can find in the books [2,3]. All the necessary information concerned automorphic system and algorithm for construction of group foliation are presented there also. The problem of group foliation construction of given system of equations was first set by Sophus Lie [8]. The group G, admitted by some system of equations E transforms any solution U: $\boldsymbol{u} = \boldsymbol{u}(\boldsymbol{x})$ into solution again. Thus, in the set of all solutions of system E the equivalence relation appears: two solutions U and U' are equivalent if they are connected by the group G transformation: $U' = TU$, $T \in G$. Each equivalence class is the orbit of one of the solutions under all possible transformations of group G. The problem of group foliation is formulated as follows: for a given system of equations E and a given group G, being admitted by system E, it is required to form a system of equations, which would describe an orbit of any solution (system AG) and a system, which would give an assemblage of all orbit of different solutions (system RE). System AG is named as *automorphic* and has a property that any its solution belongs to the orbit of one solution, i.e. any solution obtained from any other by the action of group G. On the contrary, the *resolving* system RE does not admit the original group and, thus, distinguishes the orbits of different solutions.

In present work we use Ovsiannikov's algorithm [2] for construction of group foliation. This algorithm sufficiently uses the basis of differential invariants for investigated group.

2 Preliminary information

We consider the Euler equations, which describe rotationally symmetrical motions of ideal fluid. Rotational symmetry means that in the cylindrical coordinate system (r, θ, z) all functions are assumed to be independent of the polar angle θ. Thus the system under consideration is the following:

$$\begin{aligned} &u_t + uu_r + wu_z + p_r = \frac{v^2}{r}, \\ &v_t + uv_r + wv_z = -\frac{uv}{r}, \\ &w_t + uw_r + ww_z + p_z = 0, \\ &u_r + \frac{1}{r}u + w_z = 0. \end{aligned} \tag{1}$$

Here u, v and w are velocity components which correspond to (r, θ, z) axes; p is a pressure. The admitted group for system (1) is known [9]. Its finite-dimensional part L_4 is generated by the following operators

$$\begin{aligned} &X_1 = \partial_t, \qquad X_2 = -\frac{1}{r^2 v}\partial_v + \frac{1}{r^2}\partial_p, \qquad X_3 = t\partial_t + r\partial_r + z\partial_z, \\ &X_4 = 2t\partial_t + r\partial_r + z\partial_z - u\partial_u - v\partial_v - w\partial_w - 2p\partial_p. \end{aligned} \tag{2}$$

Operators of infinite-dimensional part L_∞ of admitted group depend on two arbitrary functions of time:

$$Z_f = f(t)\partial_z + \dot{f}(t)\partial_w - \ddot{f}(t)z\partial_p, \qquad H_\varphi = \varphi(t)\partial_p. \tag{3}$$

Further we construct the group foliation of the system (1) with respect to an infinite-dimensional group L_∞ (3).

3 The representation of the solution

The first step is the calculation of the basis of differential invariants and operators of invariant differentiation of the group L_∞.

Lemma 1. *A basis of differential invariants of the group L_∞ can be chosen as follows:*

$$t, \quad r, \quad u, \quad v, \quad W_0 = w_t + ww_z + p_z, \quad W_1 = w_r, \quad W_2 = w_z, \quad P = p_r. \tag{4}$$

Operators of invariant differentiation are

$$\delta_0 = D_t + wD_z, \qquad \delta_1 = D_r, \qquad \delta_2 = D_z. \tag{5}$$

The commutative relations between δ_i are the following:

$$[\delta_0, \delta_1] = -W_1\delta_2, \qquad [\delta_0, \delta_2] = -W_2\delta_2, \qquad [\delta_1, \delta_2] = 0. \tag{6}$$

Proof. The proof is the same as in [1]. ■

As it follows from general theory the Euler equations (1) can be rewritten as a relation between differential invariants only. Since action of operators of invariant differentiation on differential invariant provides differential invariants of higher order we have the following system

$$\begin{aligned} &\delta_0 u + u\delta_1 u + P = \frac{v^2}{r}, \qquad \delta_0 v + u\delta_1 v = -\frac{uv}{r}, \\ &W_0 + uW_1 = 0, \qquad \delta_1 u + \frac{u}{r} + W_2 = 0, \end{aligned} \tag{7}$$

which is equivalent to the original equations (1). The system (7) provides the first part of relations between differential invariants.

According to the general algorithm [2] we have to choose 3 (the same number as the number of original independent variables) of the differential invariants (4) to be the new independent variables. The remaining 5 invariants from the basis further will be regarded as functions of the 3 chosen independent variables.

It is convenient to choose invariants t, r, u as the new independent variables. This choice is valid for all solutions where $u_z \neq 0$. The case $u_z = 0$ will be investigated separately. Due to the third equation of (7) the representation of solution for the group foliation has the following form:

$$w_t + ww_z + p_z = -uW_1(t,r,u), \qquad w_r = W_1(t,r,u), \qquad w_z = W_2(t,r,u),$$
$$p_r = P(t,r,u), \qquad v = V(t,r,u). \tag{8}$$

For given functions V, W_1, W_2 and P equations (7) and (8) provide an overdetermined system of nonlinear PDEs. It is a part of automorphic system AS of group foliation. Compatibility conditions of system (8) which are equations only for invariant functions V, W_1, W_2 and P give a resolving system RS of the group foliation. For convenience we use further the terminology of partially differential equations. Namely, we call functions V, W_1, W_2, P 'invariant' and function u a 'superfluous'.

4 Compatibility conditions

Here we investigate compatibility conditions of the overdetermined system (7), (8). Note that first and fourth equations (7) give the expression for derivatives of the superfluous function u:

$$\delta_0 u = \frac{u^2+V^2}{r} + uW_2 - P,$$
$$u_r = -\frac{u}{r} - W_2. \tag{9}$$

Substituting a representation of v from (8) into the second equation (7) by virtue of (9) we obtain an equation only for invariant functions

$$V_t + uV_r + \left(\frac{1}{r}V^2 - P\right)V_u = -\frac{u}{r}V. \tag{10}$$

Cross-differentiating of the second and third equations of (8) allows us to eliminate function w providing

$$W_{1u}u_z = W_{2r} - W_{2u}\left(\frac{u}{r} + W_2\right). \tag{11}$$

Then we differentiate the first equation of (8) with respect to r and subtract $\delta_0(w_r)$ and $(p_r)_z$, obtained from the second and fourth equations (8). Using equations (9) and commutative relations (6) we find

$$P_u u_z = -W_{1t} + \frac{u}{r}W_1 - uW_{1r} - W_{1u}\left(\frac{1}{r}V^2 - P\right). \tag{12}$$

Elimination of the derivative u_z from relations (11), (12) provides an additional equation for invariant functions only

$$W_{2r}P_u - W_{2u}\left(\frac{u}{r} + W_2\right)P_u + W_{1t}W_{1u} - \frac{u}{r}W_1W_{1u}$$
$$+ W_{1u}^2\left(\frac{1}{r}V^2 - P\right) + uW_{1r}W_{1u} = 0. \tag{13}$$

Next we have to derive a compatibility conditions for the superfluous function u. Hereafter we suppose that $W_{1u} \neq 0$. Case $W_{1u} = 0$ by virtue of (8) corresponds to separation of variables $w = f(t,r) + g(t,z)$. This case is not considered here. Note only that analysis of the particular case $w = f(t,r)$ serves as a topic for paper [10].

According to the above propositions all derivatives of the superfluous function u are determined from relations (9) and (11). Its cross-differentiation taking into consideration commutative relations (6) gives three equations, which involve first-order derivatives of u. Elimination of these derivatives gives three more equations for invariant functions only. Due to a big amount of calculation we present only the result:

$$
\begin{aligned}
&W_1 W_{1u}^{-1}\left(W_{2r} - \left(\frac{u}{r} + W_2\right) W_{2u}\right) = W_{2t} + uW_{2r} + \frac{2}{r}VV_r - P_r - \frac{1}{r}P \qquad (14)\\
&\quad + \left(\frac{1}{r}V^2 - P\right) W_{2u} - \frac{2u}{r}W_2 + W_2 P_u - \frac{2}{r}W_2 V V_u - \frac{2u}{r^2}VV_u + \frac{u}{r}P_u - W_2^2 - \frac{2u^2}{r^2},\\
&-W_{2tr} + \left(\frac{u}{r} + W_2\right) W_{2tu} - \left(\frac{u^2+V^2}{r} + uW_2 - P\right) W_{2ru}\\
&\quad + \left(\frac{u}{r} + W_2\right)\left(\frac{u^2+V^2}{r} + uW_2 - P\right) W_{2uu}\\
&\quad + \left(W_{2t} + uW_{2r} - \frac{2}{r}V\left(\frac{u}{r} + W_2\right) V_u - \left(\frac{u}{r} + W_2\right)\left(\frac{u}{r} - P_u\right)\right) W_{2u}\\
&\quad + \left(\frac{2u}{r} + \frac{2}{r}VV_u - P_u\right) W_{2r} + \left(\frac{1}{r}V^2 - P\right)\left(W_{2u}^2 + \frac{1}{r}W_{2u}\right)\\
&\quad = W_{1u}^{-1}\left(-W_{2r} + \left(\frac{u}{r} + W_2\right) W_{2u}\right)\left(W_{1tu} + \left(\frac{u^2+V^2}{r} + uW_2 - P\right) W_{1uu}\right), \qquad (15)\\
&W_{2rr} - 2\left(\frac{u}{r} + W_2\right) W_{2ru} + \left(\frac{u}{r} + W_2\right)^2 W_{2uu} + \frac{1}{r}W_{2r} + \frac{u}{r^2}W_{2u}\\
&\quad = W_{1u}^{-1}\left(-W_{2r} + \left(\frac{u}{r} + W_2\right) W_{2u}\right)\left(-W_{1ru} + \left(\frac{u}{r} + W_2\right) W_{1uu}\right). \qquad (16)
\end{aligned}
$$

Note that equation (16) involves only functions W_i and their derivatives. System of equations (10), (13), (14)–(16) forms an overdetermined resolving system of 5 equations for 4 functions V, W_1, W_2, P. It is necessary to investigate its compatibility.

Lemma 2. *System of equations* (10), (13), (14)–(16) *is consistent and in involution. Arbitrariness of its general solution is 4 functions of 2 arguments and 9 functions of 1 argument.*

Proof. To proof the lemma we check the Cartan criterion [11]. Having the goal to obtain second-order system of equations we differentiate all first-order equations (10), (13), (14) with respect to t, r, u. The complete second-order system (together with equations (15), (16)) consists of 11 equations including $4C_4^2 = 24$ second-order derivatives of invariant functions. Let us denote that system as E_1. The matrix of coefficients of the second derivatives in E_1 happens to be non-degenerate. We calculate the auxiliary constant $\tau_0 = 24 - 11 = 13$. Next we add the following relations to E_1

$$
V_{ti} = 0, \qquad W_{1ti} = 0, \qquad W_{2ti} = 0, \qquad P_{ti} = 0, \qquad i = t, r, u \qquad (17)
$$

(all second derivatives involving t-differentiation vanish). An extended system E_2 included 23 equations. Rank of matrix constructed from coefficients of second derivatives equals 20. Thus $\tau_1 = 24 - 20 = 4$. Further we add to E_2 the relations

$$
V_{ri} = 0, \qquad W_{1ri} = 0, \qquad W_{2ri} = 0, \qquad P_{ri} = 0, \qquad i = t, r, u \qquad (18)
$$

(all second derivatives containing r derivatives vanish). The obtained system contains 31 equations. Rank of matrix of coefficients of the second derivatives equals 24. Thus $\tau_2 = 24 - 24 = 0$.

The data obtained allows to calculate Cartan characters $\sigma_1 = \tau_0 - \tau_1 = 9$, $\sigma_2 = \tau_1 - \tau_2 = 4$, $\sigma_3 = \tau_2 = 0$. The Cartan number is $Q = \tau_0 + \tau_1 + \tau_2 = 17$. To check the Cartan criterion the third prolongation of the initial second-order system E_1 is required. Cartan criterion is satisfied if the number of 'free' third-order derivatives in prolonged system coincides with Cartan number Q. Actually, the number of all third derivatives of invariant functions is $4C_5^3 = 40$. Prolongation of E_1 allows to calculate the rank of matrix of coefficients of third derivatives. It is equal to 23. Hence $40 - 23 = 17 = Q$, i.e. the Cartan criterion for system (10), (13), (14)–(16) is satisfied. General solution of that system is determined with arbitrariness in σ_i functions of i variables. ■

Summarizing all obtained above we can formulate the following theorem.

Theorem 1. *The group foliation of equations* (1) *with respect to infinite-dimensional group* (3) *in the regular case* $u_z \neq 0$, $w_{rz} \neq 0$ *consists of resolving system* (10), (13), (14)–(16) *for invariant functions* V, W_1, W_2, P *and automorphic system* (8), (9), (11).

5 Special case $u_z = 0$

Here we observe the special case specified in the title of the paragraph. In this case variables t, r, u cannot be chosen as new independent variables for group foliation as it was done above. However it is possible to describe all 'lost' solutions. Actually, the consequence of stated condition is $u = u(t, r)$. From the last equation (1) by integration we obtain that function w linearly depends on z

$$w = -\left(u_r + \frac{u}{r}\right) z + w_0(t, r). \tag{19}$$

We substitute representation (19) into the third equation (1). After integration with respect to z we obtain pressure p to be a quadratic polynomial of variable z:

$$\begin{aligned} &p = a(t,r)z^2 - 2b(t,r)z + p_0(t,r),\\ &a(t,r) = u_{tr} + uu_{rr} + \frac{1}{r}u_t - u_r^2 - \frac{1}{r}uu_r - \frac{2}{r^2}u^2,\\ &b(t,r) = w_{0t} + uw_{0r} - \left(u_r + \frac{1}{r}u\right) w_0. \end{aligned} \tag{20}$$

Substitution of (20) into the first equation (1) allows us to express v^2 as a quadratic polynomial of variable z:

$$v^2 = r\left(u_t + uu_r + a_r z^2 - 2b_r z + p_{0r}\right). \tag{21}$$

Finally, we rewrite the second equation of (1) in the form

$$\left(v^2\right)_t + u\left(v^2\right)_r + w\left(v^2\right)_z = -\frac{2uv^2}{r}. \tag{22}$$

Substituting (19), (21) into (22) we obtain the equation which has a special form: quadratic polynomial of z equals zero. Splitting with respect to z provides a system of 3 equations for 3 unknown functions: u, w_0 and p_0. Solutions of that well-defined system completely determine an investigated class of solutions of Euler equations. It should be noted that these solutions with $u_z = 0$ were retrieved in Pukhnachov's work [12] on the base of the so-called 'heuristic' method.

Remark 1. The only unexamined case left is $w_{rz} = 0$. Its investigation is complicated by the fact that equations (1) do not split after substitution of function w. The higher-order prolongation of the obtained system is required for its completion to involution.

6 Admitted group

The resolving system RS inherits finite-dimensional part of L_4 of the group, admitted by equations (1). Action of L_4 in the space of differential invariants (4) is generated by the following operators:

$$Y_1 = \partial_t, \qquad Y_2 = -\frac{1}{r^2 V}\partial_V - \frac{2}{r^3}\partial_P, \qquad Y_3 = t\partial_t + r\partial_r - W_1\partial_{W_1} - W_2\partial_{W_2} - P\partial_P,$$
$$Y_4 = 2t\partial_t + r\partial_r - u\partial_u - v\partial_v - 2W_1\partial_{W_1} - 2W_2\partial_{W_2} - 3P\partial_P. \tag{23}$$

Group (23) can be used for construction of invariant and partially invariant solutions of the resolving system RS. The velocity components u, v, w and pressure p are restored then by means of integration of automorphic system AS. The optimal system of subalgebras [13, 14] ΘL_4 can be easily constructed. Its representatives are written below.

dim = 4

1. $\{Y_1,\ Y_2,\ Y_3,\ Y_4\}$.

dim = 3

1. $\{Y_1,\ Y_3,\ Y_4\}$, 2. $\{Y_2,\ Y_3,\ Y_4\}$, 3. $\{Y_1,\ Y_2,\ \alpha Y_3 + \beta Y_4;\ \alpha^2 + \beta^2 = 1\}$.

dim = 2

1. $\{Y_1,\ Y_2\}$, 2. $\{Y_3,\ Y_4\}$, 3. $\{Y_1,\ Y_3 + \alpha Y_4\}$, 4. $\{Y_1 + \alpha Y_2,\ 2Y_3 + Y_4\}$,
5. $\{Y_2,\ Y_3 + \alpha Y_4\}$, 6. $\{Y_1,\ \alpha Y_2 + Y_4\}$, 7. $\{Y_2,\ Y_4\}$.

dim = 1

1. $\{Y_1 + \alpha Y_2\}$, 2. $\{Y_2\}$, 3. $\{Y_3 + \alpha Y_4\}$, 4. $\{Y_1 + 2Y_3 - Y_4\}$, 5. $\{\alpha Y_2 + Y_4\}$.

Here $\{Y_1, \ldots, Y_k\}$ denotes a Lie algebra generated by basic operators $Y_1, \ldots, Y_k$; α, β are arbitrary constants.

7 Example of a partially invariant solution

Here we provide an example of a partially invariant solution for resolving system RS. We use the whole 4-dimensional group with generators (23) admitted by the resolving system RS. Invariants of L_4 in the space $\mathbb{R}^7(t, r, u, V, W_1, W_2, P)$ are

$$\frac{rW_1}{u}, \qquad \frac{rW_2}{u}, \qquad \frac{r}{u^2}\left(P - \frac{V^2}{r}\right). \tag{24}$$

All the invariant functions except for V could be expressed from invariants (24). One can construct partially invariant solution of rank 0 and defect 1. The representation of solution of resolving system RS is

$$W_1 = \frac{au}{r}, \qquad W_2 = \frac{bu}{r}, \qquad P = \frac{V^2}{r} + \frac{p_0 u^2}{r}, \qquad a, b, p_0 = \text{const}. \tag{25}$$

The non-invariant superfluous function V supposed to depend on all the variables

$$V = V(t, r, u). \tag{26}$$

The representation of solution (25), (26) is to be substituted into resolving system RS. In accordance with general theory an overdetermined system for function $V(t,r,u)$ and constants a, b, p_0 will appear. This system of 5 nonlinear equations should be completed to involution. It is consistent since it has a trivial solution. However the careful investigation of all cases, which arise during this system's compatibility analysis, is quite complicated.

To avoid this intricate process we start directly from the automorphic system AS given by formulas (8), (9), (11). We substitute the representation of solution (25), (26) into automorphic system AS and repeat all steps which were previously done to obtain the resolving system RS. Now it is simpler since invariant functions have a specific form.

Remark 2. The described algorithm provides a so-called differentially invariant solution. It can be used without any prior information about group foliation of the system (1) starting directly from optimal system of subgroups for admitted group.

Implementation of the algorithm gives the following. The solution is reduced to

$$\begin{aligned} &u = ru(t,z), \qquad v^2 = \frac{k}{r^2} - r^2u^2(t,z),\\ &w = w(t,z), \qquad p = -\frac{k}{2r^2} + p(t,z), \qquad k = \text{const}. \end{aligned} \tag{27}$$

Note that $k = 0$ modulo to Y_2 transformation. Functions $u(t,z)$, $w(t,z)$, $p(t,z)$ satisfy the system

$$u_t + wu_z = -2u^2, \qquad w_z = -2u, \qquad w_t + ww_z + p_z = 0. \tag{28}$$

Equations (28) are reduced to one key equation for function $w(t,z)$ only

$$w_{tz} + ww_{zz} = w_z^2. \tag{29}$$

Equation (29) can be an object of separate investigation. It admits infinite-dimensional group of contact transformation with the following generators:

$$\begin{aligned} &\partial_t, \qquad t\partial_t + z\partial_z, \qquad z\partial_z + w\partial_w, \qquad t^2\partial_t - tz\partial_z - (z+3tw)\partial_w,\\ &h_{w_z}\partial_z + (w_zh_{w_z} - h)\partial_w - h_t\partial_{w_t}. \end{aligned} \tag{30}$$

Here $h = h(t,w_z)$ is an arbitrary function, which satisfies the linear equation

$$h_{tw_z} + (w_z)^2h_{w_zw_z} - w_zh_{w_z} + h = 0. \tag{31}$$

Apparently it indicates that equation (29) is linearizable.

8 Conclusion

We constructed a group foliation of Euler ideal liquid equations in the rotationally symmetrical case. For group foliation we used an infinite-dimensional part of the admitted group. The resolving system RS of group foliation consists of 5 equations (two of them are second-order) for 4 sought functions of 3 variables. This system is in involution. The arbitrariness of its general solution is determined. For any solution of resolving system one can restore original functions by solving a consistent automorphic system AS.

The resolving system inherits finite-dimensional part of initial admitted group. We construct a partially invariant solution for resolving system constructed on the base of inherited transformations. This solution can be observed as a differentially invariant solution for the original Euler equations.

The symmetry reduction method is used to obtain invariant and conditionally invariant solutions of magnetohydrodynamic equations in (3+1) dimensions. Detail description of the procedure for constructing such solutions is presented. These solutions represent simple and double Riemann waves.

1 Introduction

We consider the magnetohydrodynamic (MHD) equations in (3+1) dimensions which can be written in the matrix evolutionary form

$$\mathrm{u}_t + A^1(\mathrm{u})\mathrm{u}_x + A^2(\mathrm{u})\mathrm{u}_y + A^3(\mathrm{u})\mathrm{u}_z = 0, \qquad \nabla\cdot\vec{H} = 0, \tag{1}$$

where the 8 by 8 matrix functions A^1, A^2 and A^3 have the form

$$A^1 = \begin{pmatrix} u & 0 & \rho & 0 & 0 & 0 & 0 & 0 \\ 0 & u & \kappa p & 0 & 0 & 0 & 0 & 0 \\ 0 & 1/\rho & u & 0 & 0 & 0 & H_2/\rho & H_3/\rho \\ 0 & 0 & 0 & u & 0 & 0 & -H_1/\rho & 0 \\ 0 & 0 & 0 & 0 & u & 0 & 0 & H_1/\rho \\ 0 & 0 & 0 & 0 & 0 & u & 0 & 0 \\ 0 & 0 & H_2 & -H_1 & 0 & 0 & u & 0 \\ 0 & 0 & H_3 & 0 & -H_1 & 0 & 0 & u \end{pmatrix}, \tag{2}$$

$$A^2 = \begin{pmatrix} v & 0 & \rho & 0 & 0 & 0 & 0 & 0 \\ 0 & v & \kappa p & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & v & 0 & 0 & -H_2/\rho & 0 & 0 \\ 0 & 1/\rho & 0 & v & 0 & H_1/\rho & 0 & H_3/\rho \\ 0 & 0 & 0 & 0 & v & 0 & 0 & -H_2/\rho \\ 0 & 0 & -H_2 & H_1 & 0 & v & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & v & 0 \\ 0 & 0 & 0 & H_3 & -H_2 & 0 & 0 & v \end{pmatrix},$$

and

$$A^3 = \begin{pmatrix} w & 0 & 0 & 0 & \rho & 0 & 0 & 0 \\ 0 & w & 0 & 0 & \kappa p & 0 & 0 & 0 \\ 0 & 0 & w & 0 & 0 & -H_3/\rho & 0 & 0 \\ 0 & 0 & 0 & w & 0 & 0 & -H_3/\rho & 0 \\ 0 & 1/\rho & 0 & 0 & w & H_1/\rho & H_2/\rho & 0 \\ 0 & 0 & -H_3 & 0 & H_1 & w & 0 & 0 \\ 0 & 0 & 0 & -H_3 & H_2 & 0 & w & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & w \end{pmatrix}. \tag{3}$$

Here ρ and p represent the density and the pressure of the fluid, respectively; κ is an adiabatic exponent; $\vec{\mathrm{v}} = (u, v, w)$ and $\vec{H} = (H_1, H_2, H_3)$ represent the velocity of the fluid and the magnetic field, respectively. This system describes an ideal nonstationary isentropic flow of a compressible conductive fluid (with negligible dissipative effect, and the electrical conductivity of the fluid is assumed to be infinitely large) placed in magnetic fluid $\vec{H}$. The MHD system of equations (1) is composed of nine equations involving eight unknown functions $\mathrm{u} = (\rho, p, \vec{\mathrm{v}}, \vec{H}) \in \mathbb{R}^8$.

The aim of this paper is to analyse two special cases of point symmetry of MHD equations (1) that describe the nonlinear propagation and superposition of waves. The methodological approach accepted here is based on the Lie group methods of infinitesimal transformations [1, 2]. For a comprehensive review of this subject see references [3–5]. Examples of invariant and conditionally invariant solutions of system (1) are presented, and some physical and mathematical consequences are discussed.

2 Conditionally invariant solutions and multiples waves

Consider a properly determined homogeneous quasilinear hyperbolic system of first order partial differential equations in p independent variable $\mathrm{x} = (x^1, \dots, x^p)$ and q dependent variables $\mathrm{u} = (u^1, \dots, u^q)$ of the form

$$A^i(\mathrm{u})\mathrm{u}_i = 0, \qquad i = 1, \dots, p, \tag{4}$$

where $A^1, \dots, A^p$ are $q \times q$ matrix functions of u. A vector λ is said to be a *wave vector* of the system (4) if there exists a non zero function $\lambda(\mathrm{u}) = (\lambda_1(\mathrm{u}), \dots, \lambda_p(\mathrm{u}))$ such that $\ker(\lambda_i A^i) \neq 0$. The function r of x and u is said to be a *Riemann invariant* associated to the wave vector λ if the following relation holds

$$r(\mathrm{x}, \mathrm{u}) = \lambda_i(\mathrm{u})x^i. \tag{5}$$

Now let us fix $1 \leq k \leq p$ linearly independent wave vectors $\lambda^1, \dots, \lambda^k$ with corresponding Riemann invariants

$$r^1(\mathrm{x}, \mathrm{u}) = \lambda^1_i(\mathrm{u})x^i, \dots, r^k(\mathrm{x}, \mathrm{u}) = \lambda^k_i(\mathrm{u})x^i. \tag{6}$$

The equation

$$\mathrm{u} = f\big(r^1(\mathrm{x}, \mathrm{u}), \dots, r^k(\mathrm{x}, \mathrm{u})\big) \tag{7}$$

defines a unique function u(x) on a neighborhood of $\mathrm{x} = 0$, for any function $f : \mathbb{R}^k \to \mathbb{R}^q$, and the Jacobian matrix is given by

$$\frac{\partial u^\alpha}{\partial x^i} = \big(\phi^{-1}(\mathrm{x})\big)^l_j \lambda^j_i\big(\mathrm{u}(\mathrm{x})\big)\frac{\partial f^\alpha}{\partial r^l}\big(r(\mathrm{x}, \mathrm{u})\big), \qquad l, j = 1, \dots, k,\ i = 1, \dots, p,\ \alpha = 1, \dots, q, \tag{8}$$

where the $k \times k$ matrix ϕ takes the form

$$\big(\phi\,(\mathrm{x})\big)^l_j = \delta^l_j - \frac{\partial r^l}{\partial u^\alpha}\,\frac{\partial f^\alpha}{\partial r^j}\,\big(r\,(\mathrm{x},\mathrm{u})\big). \tag{9}$$

Note that the rank of u(x) is at most equal to k. If the vector-valued function

$$\xi_a(\mathrm{u}) = \big(\xi^1_a(\mathrm{u}),\ldots,\xi^p_a(\mathrm{u})\big)^T, \qquad a = 1,\ldots,p-k \tag{10}$$

satisfies the orthogonality condition

$$\lambda^s_i \cdot \xi^i_a = 0, \qquad s = 1,\ldots,k, \quad a = 1,\ldots,p-k \tag{11}$$

then we get

$$\xi^i_a\big(u^\alpha(\mathrm{x})\big)\frac{\partial u^\alpha}{\partial x^i} = 0. \tag{12}$$

Therefore $u^1(\mathrm{x}),\ldots,u^q(\mathrm{x})$ are invariants of the vector field

$$\xi^i_a\big(\mathrm{u}(\mathrm{x})\big)\frac{\partial}{\partial x^i}, \qquad a = 1,\ldots,p-k \tag{13}$$

on $\mathbb{R}^p$. Hence the graph of a solution Γ_f is invariant under the vector field

$$X_a = \xi^i_a(\mathrm{u})\frac{\partial}{\partial x^i}, \qquad a = 1,\ldots,p-k \tag{14}$$

on $\mathbb{R}^p \times \mathbb{R}^q$. Conversely, if u(x) is a q-component function defined on a neighborhood of $\mathrm{x} = 0$ such that the graph Γ_f is invariant under all vector fields (14) with the property (11), then u(x) is the solution of (7) for some function f, because $r^1,\ldots,r^k,u^1,\ldots,u^q$ constitute a complete set of invariants of the Abelian algebra of such vector fields (14). This geometrically characterizes the solutions of the equations of the form (7). If u(x) is the solution of (7) then

$$A^i\big(\mathrm{u}(\mathrm{x})\big)\frac{\partial \mathrm{u}}{\partial x^i}(\mathrm{x}) = \big(\phi^{-1}(\mathrm{x})\big)^l_j\lambda^j_i\big(\mathrm{u}(\mathrm{x})\big)A^i\big(\mathrm{u}(\mathrm{x})\big)\frac{\partial f}{\partial r^l}\big(r\big(\mathrm{x},\mathrm{u}(\mathrm{x})\big)\big) = 0. \tag{15}$$

Now we choose an appropriate coordinate system on space $\mathbb{R}^p \times \mathbb{R}^q$ in order to rectify the vector fields (14). We assume that the k by k matrix

$$\Lambda = \big(\lambda^i_j\big), \qquad 1 \le i,\, j \le k \tag{16}$$

is invertible. The independent vector fields

$$X_{k+1} = \frac{\partial}{\partial x^{k+1}} - \sum_{i,j=1}^{k}\big(\Lambda^{-1}\big)^j_i\lambda^i_{k+1}\frac{\partial}{\partial x^j}, \quad \ldots, \quad X_p = \frac{\partial}{\partial x^p} - \sum_{i,j=1}^{k}\big(\Lambda^{-1}\big)^j_i\lambda^i_p\frac{\partial}{\partial x^j} \tag{17}$$

have the required form (14) with the orthogonality property (7). If we change the independent and dependent variables as follows

$$\overline{x}^1 = r^1(\mathrm{x},\mathrm{u}),\ \ldots,\ \overline{x}^k = r^k(\mathrm{x},\mathrm{u}),\ \overline{x}^{k+1} = x^{k+1},\ \ldots,\ \overline{x}^p = r^p,\ \overline{u}^1 = u^1,\ \ldots,\ \overline{u}^q = u^q \tag{18}$$

then the vector fields (17) take rectified form

$$X_{k+1} = \frac{\partial}{\partial \overline{x}^{k+1}}, \quad \ldots, \quad X_p = \frac{\partial}{\partial \overline{x}^{\,p}}. \tag{19}$$

The graph of the solution Γ_f invariant under $X_{\kappa+1}, \dots, X_p$ is defined by equations of the form

$$\overline{\mathrm{u}}(\overline{\mathrm{x}}) = f\big(\overline{x}^1, \dots, \overline{x}^k\big), \tag{20}$$

where $f : \mathbb{R}^k \to \mathbb{R}^q$ is an arbitrary function. This implies that expression (20) is the general solution of the invariance conditions

$$\overline{\mathrm{u}}_{\overline{k+1}} = 0, \quad \dots, \quad \overline{\mathrm{u}}_{\overline{p}} = 0. \tag{21}$$

The system (4) is described in the coordinates $(\overline{\mathrm{x}}, \overline{\mathrm{u}})$ by

$$\overline{A}^{\,i}\big(\overline{\mathrm{x}}, \overline{\mathrm{u}}, \overline{\mathrm{u}}_{\overline{\mathrm{x}}}\big)\overline{\mathrm{u}}_{\overline{i}} = 0, \tag{22}$$

where,

$$\overline{A}^{\,1} = \frac{Dr^1}{Dx^i}\,A^i, \ \dots, \ \overline{A}^{\,k} = \frac{Dr^k}{Dx^i}A^i, \quad \overline{A}^{\,k+1} = A^{k+1}, \ \dots, \ \overline{A}^{\,p} = A^p. \tag{23}$$

Now, we have

$$\left.\frac{Dr^i}{Dx^i}\right|_{\overline{\mathrm{u}}_{\overline{k+1}},\dots,\overline{\mathrm{u}}_{\overline{p}}=0} = \big(\Phi^{-1}\big)^i_{\ j}\lambda^j_i, \quad \text{where} \quad \big(\Phi^{-1}\big)^i_{\ j} = \delta^i_j - \frac{\partial r^i}{\partial \overline{u}^{\,\alpha}}\overline{u}^\alpha_j, \quad i,j = 1,\dots,k. \tag{24}$$

Adding the invariance conditions (21) to the system (22) we obtain the reduced system of the form

$$\sum_{i,j=1}^{k}\sum_{i=1}^{p}\big(\Phi^{-1}\big)^i_{\ j}\lambda^j_i A^i\overline{\mathrm{u}}_{\overline{i}} = 0, \qquad \overline{\mathrm{u}}_{\overline{k+1}} = 0, \ \dots, \ \overline{\mathrm{u}}_{\overline{p}} = 0, \tag{25}$$

which must then be solved.

3 Double Alfvén-entropic wave

Using a version of the conditional symmetry method presented above we construct an example of a double Alfvén-entropic wave. According to the proposed method we consider the case where two wave vectors λ^1 and λ^2 corresponding to the Alfvén and entropic wave vectors are given by

$$\lambda^1 = \big(\delta_A - (\vec{\lambda}^1 \cdot \vec{\mathrm{v}}), \vec{\lambda}^1\big), \quad \lambda^2 = \big(-(\vec{\lambda}^2 \cdot \vec{\mathrm{v}}), \vec{\lambda}^2\big), \quad \delta_A = \varepsilon\frac{(\vec{H}\cdot\vec{\lambda}^1)}{\sqrt{\rho}}, \quad \varepsilon = \pm 1, \tag{26}$$

$$\vec{\lambda}^1 = (\cos\varphi, \sin\varphi, 0), \quad \vec{\lambda}^2 = (\cos\theta, \sin\theta, 0). \tag{27}$$

We consider additionally two vectors ξ_1, ξ_2 which are orthogonal to the given vectors λ^1 and λ^2. We look for the graph of the double wave solution which is invariant under these vector fields

$$\begin{aligned} X_1 &= \sin(\theta-\varphi)\frac{\partial}{\partial t} - [\delta_A\sin\theta + u\sin(\varphi-\theta)]\frac{\partial}{\partial x} + [\delta_A\cos\theta + v\sin(\theta-\varphi)]\frac{\partial}{\partial y}, \\ X_2 &= \frac{\partial}{\partial z}. \end{aligned} \tag{28}$$

Note that the vector fields X_1 and X_2 form an Abelian distribution on the space $\mathcal{M} \subset \mathbb{R}^4 \times \mathbb{R}^8$, i.e. $[X_1, X_2] = 0$. This requirement constitutes the necessary and sufficient conditions for the existence of a local curvilinear system of coordinates on the integral surface spanned by the fields

X_1 and X_2 in the space $\mathcal{M}$. Hence the unknown functions can be written in the parametric form $\mathrm{u} = f(r,s)$ where r and s are the Riemann invariants of the vector fields X_1 and X_2

$$r = \vec{\lambda}^2 \cdot \vec{\mathrm{x}} - (\vec{\lambda}^2 \cdot \vec{\mathrm{v}}), \qquad s = \vec{\lambda}^1 \cdot \vec{\mathrm{x}} + \big(\delta_A - (\vec{\lambda}^1 \cdot \vec{\mathrm{v}})\big)t. \tag{29}$$

Substituting the unknown functions in term of r and s into the MHD equations (1) we obtain the following solution

$$\begin{aligned} &\rho = \rho(r), \qquad p(r) + \frac{1}{2}\mathcal{H}^2(r) = p_0, \qquad \vec{\mathrm{v}} = \frac{\varepsilon \vec{H}}{\sqrt{\rho(r)}} + w(r)\vec{e}_3, \\ &\vec{H} = \mathcal{H}(r)[\cos\varphi(s)\vec{e}_1 + \sin\varphi(s)\vec{e}_2], \qquad p_0 \in \mathbb{R}, \qquad \varepsilon = \pm 1, \end{aligned} \tag{30}$$

where ρ, p, w, $\mathcal{H}$ and φ are arbitrary functions of their arguments

$$r = y\cos\varphi - x\sin\varphi, \qquad s = x\cos\varphi + y\sin\varphi, \tag{31}$$

and $\vec{e}_i$, $i = 1,2,3$ denote the constant unit vectors along x, y, z axes of $\mathbb{R}^3$. Note that the rank of the solution determined by equations (30) and (31) is equal two. The Alfvén-entropic double wave describes a stationary incompressible fluid flow. We have an equilibrium between hydrodynamic and magnetic pressures resulting from the entropic wave. We notice that the density ρ and the pressure p are unchanged by the Alfvén wave. They do however depend on the Riemann invariant r, which is related to the entropic wave.

4 Spherically invariant solution

We intend now to discuss the construction of nonstationary spherically symmetric solution of the MHD equations (1). For the purpose of this investigation we limit ourselves to the reduction obtained from the subalgebra

$$g_1 = \operatorname{span}\big\{J_1, J_2, J_3\big\}, \tag{32}$$

where the infinitesimal generators are of the form

$$\begin{aligned} J_1 &= z\partial_y - y\partial_z + w\partial_v - v\partial_w + H_3\partial_{H_2} - H_2\partial_{H_3}, \\ J_2 &= x\partial_z - z\partial_x + u\partial_w - w\partial_u + H_1\partial_{H_3} - H_3\partial_{H_1}, \\ J_3 &= y\partial_x - x\partial_y + v\partial_u - u\partial_v + H_2\partial_{H_1} - H_1\partial_{H_2}. \end{aligned} \tag{33}$$

Note that for the subalgebra g_1 the transversality condition is not satisfied

$$\operatorname{rank}\{\Omega_1\} < \operatorname{rank}\{\Omega_2\}, \tag{34}$$

where matrices Ω_1 and Ω_2 are of the form

$$\Omega_1 = \begin{pmatrix} 0 & z & -y \\ -z & 0 & x \\ y & -x & 0 \end{pmatrix}, \qquad \Omega_2 = \begin{pmatrix} 0 & z & -y & 0 & w & -v & 0 & H_3 & -H_2 \\ -z & 0 & x & -w & 0 & u & -H_3 & 0 & H_1 \\ y & -x & 0 & v & -u & 0 & H_2 & -H_1 & 0 \end{pmatrix}, \tag{35}$$

and in principle the classical symmetry reduction method cannot be applied. However, there exists a certain domain $\mathcal{D}$ given by

$$u^j = x^j f(t,x,y,z), \qquad H_j = x^j g(t,x,y,z), \qquad j = 1,2,3 \tag{36}$$

for which the rank condition is fulfilled, i.e.,

$$\operatorname{rank}\{\Omega_1\}\big|_{\mathcal{D}} = \operatorname{rank}\{\Omega_2\}\big|_{\mathcal{D}}. \tag{37}$$

In this case the subgroup G_1 acts regularly and transversally and invariant solutions can be constructed [2]. The corresponding invariants of subalgebra g_1 are

$$\begin{aligned} &t, \quad s=\sqrt{x^2+y^2+z^2}, \quad \Phi^1=\sqrt{u^2+v^2+w^2}, \quad \Phi^2=xu+yv+zw,\\ &\Phi^3=\sqrt{H_1^2+H_2^2+H_3^2}, \quad \Phi^4=xH_1+yH_2+zH_3, \quad \Phi^5=\rho, \quad \Phi^6=p. \end{aligned} \tag{38}$$

Note that the condition

$$\operatorname{rank}\left(\frac{\partial\Phi^i}{\partial u^j}\right)=7, \qquad i=1,\dots,6, \quad j=1,\dots,8 \tag{39}$$

implies that the dimension of the graph of the solution Γ_f is not preserved by the action of the symmetry group G_1. Therefore, we cannot obtain invariant solutions from this set of invariants by the classical symmetry reduction method. This is due to the fact that the defect structure δ of the solution with respect the the group G_1 is equal to one, because the rank of the characteristic matrix Q associated to the subalgebra g_1 is equal to one

$$\delta=\operatorname{rank}\left(\mathrm{Q}\big(\mathrm{x},u^{(1)}\big)\right)=1. \tag{40}$$

The graph of the solution sweeps out an orbit of dimension $\dim(G_1\Gamma_f)=p+\delta=5$. The equations determining the orbit of the graph of the solution are given by

$$\begin{aligned} &\rho=R(t,s), \qquad p=A(t,s), \qquad v=\frac{(V-xu)-zw}{y},\\ &w=\frac{z(V-xu)+\varepsilon y\sqrt{[U^2-u^2](y^2+z^2)-(xu-V)^2}}{y^2+z^2}, \qquad H_2=\frac{(X-xH_1)-zH_3}{y^2+z^2},\\ &H_3=\frac{z(Y-xH_1)+\varepsilon y\sqrt{[X^2-H_1^2](y^2+z^2)-(xH_1-Y)^2}}{y^2+z^2}, \qquad \varepsilon=\pm1, \end{aligned} \tag{41}$$

where u and H_1 are arbitrary functions of (t,x,y,z); $\Phi^2=V(t,s)$, $\Phi^3=X(t,s)$, $\Phi^4=Y(t,s)$, $\Phi^5=R(t,s)$ and $\Phi^6=A(t,s)$ are arbitrary functions of their arguments. Assuming that conditions (36) and $p=A_0\rho^\kappa$ hold and substituting (41) into the MHD equations (1) we find the reduced system

$$\begin{aligned} &\frac{\partial R}{\partial s}+sf\frac{\partial R}{\partial s}+\left(3f+s\frac{\partial f}{\partial s}\right)R=0,\\ &\frac{\partial f}{\partial t}+\left(f+s\frac{\partial f}{\partial s}\right)f+\kappa\frac{A_0}{s}R^{(\kappa-2)}\frac{\partial R}{\partial s}=0,\\ &3g+s\frac{\partial g}{\partial s}=0, \qquad A_0\in\mathbb{R}. \end{aligned} \tag{42}$$

Using the method of separation of variables we can solve system (42). We obtain the following invariant solution

$$\begin{aligned} &\rho=\rho_o\left[\frac{s^2}{2\alpha}\frac{d^2\alpha}{dt^2}-\frac{s^2}{\alpha^2}\left(\frac{d\alpha}{dt}\right)^2+C_1\alpha^{3(\kappa-1)}\right]^{1/(\kappa-1)},\\ &p=A_o\rho^\kappa, \qquad u^j=-\frac{x^j}{\alpha}\frac{d\alpha}{dt}, \qquad H_j=\frac{\alpha}{s^3}x^j, \end{aligned} \tag{43}$$

where

$$\rho_0 = \left(\frac{\kappa-1}{\kappa A_0}\right)^{1/(\kappa-1)}, \qquad \alpha(t) = C_2 \exp\left[\int \eta(t')\,dt'\right], \qquad C_1, C_2 \in \mathbb{R}, \quad j = 1,2,3. \tag{44}$$

The function η satisfies the ordinary differential equation

$$\frac{d^2\eta}{dt^2} - (1+3\kappa)\eta\frac{d\eta}{dt} + (3\kappa-1)\eta^3 = 0 \tag{45}$$

which can be solved as follows. First, we introduce the change of variable

$$\zeta(\eta) = \frac{d\eta}{dt}, \tag{46}$$

so that the equation (45) can be rewritten as

$$\zeta\frac{d\zeta}{d\eta} - (1+3\kappa)\eta\zeta + (3\kappa-1)\eta^3 = 0. \tag{47}$$

Using the second change of variable

$$\zeta(\eta) = \eta^2\chi(\tau), \qquad \text{where} \quad \tau = \ln\eta, \tag{48}$$

we solve (47) to finally obtain

$$\tau = -\int \frac{\chi d\chi}{2\chi^2 - (1+3\kappa)\chi + (3\kappa-1)} + \tau_0, \qquad \tau_0 \in \mathbb{R}. \tag{49}$$

The solution (43) represents a nonstationary compressible irrotational fluid flow for which, according Kelvin's Theorem, the circulation around a fluid element is preserved. Note that $\vec{F}_m \cdot \vec{\mathrm{v}} = 0$ which indicates that the interaction effect between the hydrodynamic and magnetic expressions in the MHD equations can be decoupled.

This paper presents a short summary of results on classification of a class of third-order nonlinear evolution equations with respect to Lie point symmetries. The approach we take is a suitable combination of the concept of equivalence group with the usual infinitesimal technique of Lie based on several results on the structure of low-dimensional Lie algebras.

1 Introduction

We classify third-order KdV-type nonlinear evolution equations containing an arbitrary element F of the form

$$u_t = u_{xxx} + F(x, t, u, u_x, u_{xx}), \tag{1}$$

where F is a smooth real-valued function of its arguments that admits nontrivial symmetry groups.

We adopt the approach applied to the classification of several partial differential equations such as the most general second order quasi-linear heat-conductivity equation and the Schrödinger equation [1–3]. The approach is basically a combination of Lie's infinitesimal method and the use of equivalence transformations and the classification theory of abstract finite-dimensional Lie algebras.

We implement this classification in an algorithmic way in the following steps. The first step of the procedure is to find the most general form of the symmetry group of the equation under study using the standard Lie algorithm [4–6]. This is equivalent to solving a first order system of linear PDEs. In effect, the coefficients of the infinitesimal generator will satisfy certain relations connecting them with the arbitrary term and its derivatives. We then use the direct method (or, equivalently, infinitesimal one) to construct the equivalence group of the equation.

In the second step, we classify realizations of finite-dimensional Lie algebras by vector fields of the above form up to equivalence transformations. To this end, we use various results on the structure of abstract Lie algebras [7–11]. In the last step, after transforming symmetry generators to canonical forms, we proceed to classifying equations that admit nontrivial symmetries. We do this by inserting these generators into the symmetry condition and solving for F. With the increasing dimension of the realized algebras, the form of the arbitrary element will be restricted. Typically we continue this procedure until the arbitrary term figuring in the equation is completely specified. At this stage, the obtained equations are expected to depend on arbitrary parameters at most and it is easily checked by Lie algorithm whether the symmetry algebras obtained can be maximal among all those leaving invariant the equation under study.

The full details of the group classification of (1) can be found in [12].

2 Determining equations and equivalence transformations

Lie algebra of the symmetry group of equation (1) is realized by vector fields of the form

$$X = \tau(x,t,u)\partial_t + \xi(x,t,u)\partial_x + \phi(x,t,u)\partial_u. \tag{2}$$

Applying the standard Lie algorithm we have

Proposition 1. *The symmetry group of the nonlinear equation* (1) *for an arbitrary (fixed) function F is generated by the vector field*

$$X = \tau(t)\partial_t + \left(\frac{\dot\tau}{3}x + \rho(t)\right)\partial_x + \phi(x,t,u)\partial_u, \tag{3}$$

where the functions $\tau(t)$, $\rho(t)$ and $\phi(x,t,u)$ satisfy the determining equation

$$\begin{aligned} &-3u_x\dot\rho - xu_x\ddot\tau - 9u_xu_{xx}\phi_{uu} - 3{u_x}^3\phi_{uuu} \\ &\quad + 3\phi_t - 9u_{xx}\phi_{xu} - 9{u_x}^2\phi_{xuu} - 9u_x\phi_{xxu} - 3\phi_{xxx} + 3\left(\phi_u - \dot\tau\right)F \\ &\quad + \left(2u_{xx}\dot\tau - 3u_{xx}\phi_u - 3{u_x}^2\phi_{uu} - 6u_x\phi_{xu} - 3\phi_{xx}\right)F_{u_{xx}} \\ &\quad + \left(u_x\dot\tau - 3u_x\phi_u - 3\phi_x\right)F_{u_x} - 3\phi F_u - 3\tau F_t - (3\rho + x\dot\tau)F_x = 0. \end{aligned} \tag{4}$$

Here the dot over a symbol stands for time derivative.

Next we construct the local group of point transformations preserving the form of the equation but possibly changing the function F. We require that equation (1) be preserved by local point transformations

$$\tilde t = T(x,t,u), \qquad \tilde x = Y(x,t,u), \qquad \tilde u = U(x,t,u), \tag{5}$$

where

$$\frac{D(T,Y,U)}{D(t,x,u)} \neq 0.$$

This requirement constrains the form of the transformation and we obtain the following assertion

Proposition 2. *The maximal equivalence group $\mathcal{E}$ has the form*

$$\tilde t = T(t), \qquad \tilde x = \dot T^{1/3}x + Y(t), \qquad \tilde u = U(x,t,u), \tag{6}$$

where $\dot T \neq 0$, $U_u \neq 0$.

Proposition 3. *Vector field* (3) *is equivalent within a point transformation of the form* (5) *to one of the following vector fields:*

$$X = \partial_t, \qquad X = \partial_x, \qquad X = \partial_u. \tag{7}$$

Proof. Transformation (6) transform vector field (3) into

$$\begin{aligned} X \to \tilde X = \tau(t)\dot T(t)\partial_{\tilde t} &+ \left[\frac{1}{3}(\tau\dot T^{-1}\ddot T + \dot\tau)(\tilde x - Y) + \tau\dot Y + \rho\dot T^{1/3}\right]\partial_{\tilde x} \\ &+ \left[\tau U_t + \left(\frac{1}{3}\dot\tau x + \rho\right)U_x + \phi U_u\right]\partial_{\tilde u}. \end{aligned} \tag{8}$$

There are two cases to consider:

i) $\phi = 0$. Choose $U = U(u)$ so that we have

$$\tilde{X} = \tau(t)\dot{T}(t)\partial_{\tilde{t}} + \left[\frac{1}{3}(\tau\dot{T}^{-1}\ddot{T} + \dot{\tau})(\tilde{x} - Y) + \tau\dot{Y} + \rho\dot{T}^{1/3}\right]\partial_{\tilde{x}} + \phi U_u \partial_{\tilde{u}}. \tag{9}$$

Now if $\tau = 0$, then $\rho \neq 0$ (otherwise X would be zero) we choose $T(t)$ to satisfy

$$\dot{T} = \rho^{-3}.$$

In this case $\tilde{X}$ is transformed into $\partial_{\tilde{x}}$.

If $\tau \neq 0$, then we choose T and Y to satisfy

$$\dot{T} = \tau^{-1}, \qquad \tau\dot{Y} + \rho\dot{T}^{1/3} = 0.$$

With this choice of T and Y vector field $\tilde{X}$ is transformed into $\partial_{\tilde{t}}$.

ii) $\phi \neq 0$. If $\tau = \rho = 0$ then we can choose U to satisfy $\phi U_u = 1$ so that we have $\tilde{X} = \partial_{\tilde{u}}$. Otherwise, U can be chosen to satisfy

$$\tau U_t + \left(\frac{1}{3}\dot{\tau}x + \rho\right)U_x + \phi U_u = 0.$$

Hence we recover Case i.

Summing up, the vector field (3) is equivalent, up to equivalence under $\mathcal{E}$, to one of the three standard vector fields ∂_x, ∂_t, ∂_u. This completes the proof. ■

3 Classification of equations invariant under semi-simple algebras and algebras having nontrivial Levi decompositions

We start out by classifying equations (1) that admit Lie algebras isomorphic to the Lie algebras having nontrivial Levi decomposition. To achieve this, we construct equations admitting semi-simple Lie algebras as invariance algebra.

The lowest order semi-simple Lie algebras are isomorphic to one of the following three-dimensional algebras:

$$\begin{aligned}
&\mathrm{sl}(2,\mathbb{R}): \quad [X_1, X_3] = -2X_2, \quad [X_1, X_2] = X_1, \quad [X_2, X_3] = X_3;\\
&\mathrm{so}(3): \quad [X_1, X_2] = X_3, \quad [X_2, X_3] = X_1, \quad [X_3, X_1] = X_2.
\end{aligned}$$

Using these commutation relations one can show that there is no realization of so(3) in terms of vector fields (3). We conclude that we cannot have so(3)-invariant equation of the form (1).

Theorem 1. *There exist no realizations of the algebra* so(3) *in terms of vector fields* (3)*. Hence no equation of the form* (1) *is invariant under* so(3) *algebra.*

There are three inequivalent realizations of the algebra $\mathrm{sl}(2,\mathbb{R})$ by operators of the form (2)

$$\begin{aligned}
&\left\{\partial_t, t\partial_t + \frac{1}{3}x\partial_x, -t^2\partial_t - \frac{2}{3}tx\partial_x\right\},\\
&\left\{\partial_t, t\partial_t + \frac{1}{3}x\partial_x, -t^2\partial_t - \frac{2}{3}tx\partial_x - x^3\partial_u\right\},\\
&\left\{\partial_u, u\partial_u, -u^2\partial_u\right\}.
\end{aligned}$$

Inserting the coefficients of basis operators of the above realizations of the algebra $\mathrm{sl}(2,\mathbb{R})$ into invariance relation (4) and solving and analyzing for their maximality we arrive at the following two theorems.

Theorem 2. *The class of PDEs* (1) *contains two inequivalent equations whose invariance algebra are semi-simple* ($\mathrm{sl}(2,\mathbb{R})$)

$$u_t = u_{xxx} - \frac{3}{2}u_x^{-1}u_{xx}^2 + u_x G(x,t);$$
$$u_t = u_{xxx} - x^{-3}\left[2xu_x + \frac{1}{9}x^2u_x^2 - G(\omega_1,\omega_2)\right], \qquad \omega_1 = 3u - xu_x, \quad \omega_2 = 6u - x^2u_{xx}.$$

The maximal invariance algebras of the above equations for arbitrary G are

$$\mathrm{sl}^1(2,\mathbb{R}) = \left\{\partial_u, u\partial_u, -u^2\partial_u\right\};$$
$$\mathrm{sl}^2(2,\mathbb{R}) = \left\{\partial_t, t\partial_t + \frac{1}{3}x\partial_x, -t^2\partial_t - \frac{2}{3}tx\partial_x - x^3\partial_u\right\}.$$

Theorem 3. *Nonlinear equation* (1) *whose invariance algebra is isomorphic to a Lie algebra having non-trivial Levi decomposition is represented by one of the following equations:*

$$u_t = u_{xxx} - \frac{3}{2}u_x^{-1}u_{xx}^2 + u_x\tilde{G}(x), \quad \mathrm{sl}^1(2,\mathbb{R}) \oplus \{\partial_t\}; \tag{10}$$
$$u_t = u_{xxx} - \frac{3}{2}u_x^{-1}u_{xx}^2 + \lambda x^{-2}u_x, \quad \lambda \neq 0, \quad \mathrm{sl}^1(2,\mathbb{R}) \oplus \left\{\partial_t, t\partial_t + \frac{1}{3}x\partial_x\right\}; \tag{11}$$
$$u_t = u_{xxx} - \frac{3}{2}u_x^{-1}u_{xx}^2, \quad \mathrm{sl}^1(2,\mathbb{R}) \oplus \left\{\partial_t, \partial_x, t\partial_t + \frac{1}{3}x\partial_x\right\}; \tag{12}$$
$$u_t = u_{xxx} - 2x^{-2}u_x - \frac{1}{9}x^{-1}u_x^2 + x^{-3}\tilde{G}(\sigma), \quad \sigma = x^2u_{xx} - 2xu_x, \quad \mathrm{sl}^2(2,\mathbb{R}) \oplus \{\partial_u\}, \tag{13}$$

where $\tilde{G}$ is an arbitrary function of x or σ. Moreover, the associated symmetry algebras are maximal.

4 Equations invariant under solvable algebras

4.1 Equations with one-dimensional symmetry algebras

Given an F we assume that equation (1) is invariant under one-dimensional symmetry groups whose canonical forms are generated by translational vector fields ∂_t, ∂_x and ∂_u (Proposition 3):

$$A_{1,1}: \ X_1 = \partial_t, \qquad A_{1,2}: \ X_1 = \partial_x, \qquad A_{1,3}: \ X_1 = \partial_u. \tag{14}$$

The corresponding invariant equations will have the form

$$A_{1,1}: \quad u_t = u_{xxx} + F(x,u,u_x,u_{xx}), \tag{15a}$$
$$A_{1,2}: \quad u_t = u_{xxx} + F(t,u,u_x,u_{xx}), \tag{15b}$$
$$A_{1,3}: \quad u_t = u_{xxx} + F(x,t,u_x,u_{xx}). \tag{15c}$$

4.2 Equations with two-dimensional symmetry algebras

There are two isomorphy classes of two-dimensional Lie algebras, Abelian and non-Abelian satisfying the commutation relations $[X_1,X_2] = \kappa X_2$, $\kappa = 0, 1$. We denote them by $A_{2,1}$ and $A_{2,2}$:

$$A_{2.1}: \ [X_1,X_2] = 0, \qquad A_{2.2}: \ [X_1,X_2] = X_2. \tag{16}$$

We construct all inequivalent realizations of the algebras $A_{2,1}$, $A_{2,2}$ in terms of infinitesimal operators (3) and obtain nine classes of two-dimensional algebras altogether. The representatives of equivalence classes of invariant equations are again found by substituting the coefficients in the symmetry condition (4). By doing this, the form of F in (15) is further restricted and the number of variables of F is reduced from four to three.

Theorem 4. *There exist nine classes of two-dimensional symmetry algebras admitted by equation* (1)*. Those algebras and functions F are represented by*

$$
\begin{aligned}
&A^1_{2,1}:\ X_1=\partial_t,\quad X_2=\partial_x,\quad F=F(u,u_x,u_{xx}),\\
&A^2_{2,1}:\ X_1=\partial_t,\quad X_2=\partial_u,\quad F=F(x,u_x,u_{xx}),\\
&A^3_{2,1}:\ X_1=\partial_x,\quad X_2=\alpha(t)\partial_x+\partial_u,\quad F=-\dot\alpha u u_x+\tilde F(t,u_x,u_{xx}),\\
&A^4_{2,1}:\ X_1=\partial_u,\quad X_2=g(x,t)\partial_u,\quad g_x\neq\text{const},\\
&\qquad F=(g_t-g_{xxx})g_x^{-1}u_x+\tilde F(x,t,\omega),\quad \omega=g_{xx}u_x-g_xu_{xx},\\
&A^1_{2,2}:\ X_1=\partial_t,\quad X_2=-t\partial_t-\frac{x}{3}\partial_x,\\
&\qquad F=x^{-3}\tilde F(u,\omega_1,\omega_2),\quad \omega_1=xu_x,\quad \omega_2=x^2u_{xx},\\
&A^2_{2,2}:\ X_1=-3t\partial_t-x\partial_x,\quad X_2=\partial_x,\\
&\qquad F=t^{-1}\tilde F(u,\omega_1,\omega_2),\quad \omega_1=t^{1/3}u_x,\quad \omega_2=t^{2/3}u_{xx},\\
&A^3_{2,2}:\ X_1=-u\partial_u,\quad X_2=\partial_u,\quad F=u_x\tilde F(x,t,\omega),\quad \omega=u_x^{-1}u_{xx},\\
&A^4_{2,2}:\ X_1=\partial_x-u\partial_u,\quad X_2=\partial_u,\\
&\qquad F=e^{-x}\tilde F(t,\omega_1,\omega_2),\quad \omega_1=e^xu_x,\quad \omega_2=e^xu_{xx},\\
&A^5_{2,2}:\ X_1=\partial_t-u\partial_u,\quad X_2=\partial_u,\\
&\qquad F=u_x\tilde F(x,\omega_1,\omega_2),\quad \omega_1=e^tu_x,\quad \omega_2=e^tu_{xx}.
\end{aligned}
$$

4.3 Equations with three-dimensional symmetry algebras

Two classes of decomposable three-dimensional Lie algebras exist over $\mathbb{R}$. Six classes of indecomposable three-dimensional Lie algebras exist over $\mathbb{R}$.

The decomposable three-dimensional algebras are represented by

$$A_{3,1}=3A_1=A_1\oplus A_2\oplus A_3$$

with $[X_i,X_j]=0$ for $i,j=1,2,3$ and

$$A_{3,2}=A_{2,2}\oplus A_1$$

with $[X_1,X_2]=X_2$, $[X_1,X_3]=0$, $[X_2,X_3]=0$.

A solvable three-dimensional Lie algebra has a two-dimensional Abelian ideal. We choose X_1 and X_2 as basis elements of the ideal. The commutation relations can be represented in the matrix notation

$$\begin{pmatrix}[X_1,X_3]\\ [X_2,X_3]\end{pmatrix}=J\begin{pmatrix}X_1\\ X_2\end{pmatrix},\qquad [X_1,X_2]=0,$$

where $J\in\mathbb{M}^{2\times2}$ can be chosen in its Jordan canonical form.

Over $\mathbb{R}$ we have

$$
\begin{aligned}
&A_{3.3}:\ J=\begin{pmatrix}0&0\\1&0\end{pmatrix},\qquad A_{3.4}:\ J=\begin{pmatrix}1&0\\1&1\end{pmatrix},\qquad A_{3.5}:\ J=\begin{pmatrix}1&0\\0&1\end{pmatrix},\\
&A_{3.6}:J=\begin{pmatrix}1&0\\0&-1\end{pmatrix},\qquad A_{3.7}:\ J=\begin{pmatrix}1&0\\0&q\end{pmatrix},\quad 0<|q|<1,\\
&A_{3.8}:\ J=\begin{pmatrix}0&-1\\1&0\end{pmatrix},\qquad A_{3.9}:\ J=\begin{pmatrix}q&-1\\1&q\end{pmatrix},\quad q>0.
\end{aligned}
$$

Two of them, $A_{3.7}$ and $A_{3.9}$ depend on a continuous parameter q. Once algebras in the above list have been realized we can proceed to construct invariant equations (see [12] for details). The final result on three-dimensional symmetry algebras can be summed up as a theorem.

Theorem 5. *There are thirty-eight inequivalent three-dimensional solvable symmetry algebras admitted by equation* (1).

The explicit forms of those algebras as well as the associated invariant equations are given in [12].

5 Equations with four-dimensional solvable algebras

Ten isomorphism classes of decomposable four-dimensional Lie algebras and twelve decomposable ones exist. Omitting the details we present the result as a theorem. For the forms of inequivalent realizations of four-dimensional algebras and the corresponding invariant equations the reader is referred to Ref. [12].

Theorem 6. *There exist fifty-two inequivalent four-dimensional symmetry algebras admitted by equation* (1).

Again, the realizations of these algebras and the corresponding functions F are too long to present here. The interested reader should consult Ref. [12].

Finally we mention that we performed group classification of the most general third-order linear PDE. To our surprise we established that the nontrivial symmetry group is four-dimensional at most. However, as confirmed by the results of this work, there are nonlinear equations with larger symmetry groups than that of the linear equation. This situation is not the case for second-order PDEs.

Applications of Symmetry to General Relativity

B. Kent HARRISON

Physics and Astronomy Department, Brigham Young University, Provo, Utah 84602, USA
E-mail: *bkentharrison@comcast.net, bkh@byu.edu*

The equations of general relativity are highly nonlinear partial differential equations and require special techniques to solve exactly. Symmetry considerations have sometimes helped to find solutions. Three examples will be considered here. The first one considers a scaling symmetry in the equations for perfect fluid with a spherical symmetry, which is of historical importance in understanding neutron stars and black holes. The second involves symmetries in the Ernst equation for stationary axially symmetric fields, which are related to the methods worked out in the 1970s for finding solutions to that equation. The third example is an ongoing investigation into critical gravitational collapse, a topic of current interest, using a symmetry of the equations and other analytic techniques.

1 Introduction

The Einstein equations of general relativity are, in general, second order highly nonlinear partial differential equations. It has been necessary to employ many different techniques in order to obtain exact solutions of these equations, and many are now known. I will discuss here a few examples of the use of symmetry in such investigations. First I will present some cases of historical interest, and then I will treat, more extensively, a current ongoing research problem.

2 Spherically symmetric configurations

My first example has to do with spherically symmetric gravitational fields for a perfect fluid. The first solution of the vacuum Einstein's equations to be found was the Schwarzschild solution,

$$ds^2 = -(1-2m/r)dt^2 + (1-2m/r)^{-1}dr^2 + r^2 d\theta^2 + r^2\sin^2\theta d\phi^2$$

which is the spherically symmetric solution for a point mass m and which later proved the foundation for the discovery of black holes. In this equation $G = c = 1$. For a perfect fluid, the equations for pressure P, density ρ, and mass m out to radius r take the Oppenheimer–Volkoff form [1],

$$dP/dr = -(P+\rho)\left(m + 4\pi r^3 P\right)/r(r-2m), \tag{1}$$

$$dm/dr = 4\pi r^2 \rho \tag{2}$$

in which there is assumed an equation of state $P = P(\rho)$. For high densities we expect the equation of state to take the form $P = k\rho$, where k is a constant, which takes the value $1/3$ for a Fermi gas of neutrons, protons, and electrons. In this case, one can see that equations (1) and (2) admit a scaling symmetry. If we write $a = m/r$ and $b = 4\pi r^2\rho/3m$ and take $k = 1/3$, these equations become [2]

$$rda/dr = a(3b-1),$$
$$rdb/dr = b[3 - 3b - 4a(3+b)/(1-2a)].$$

Division of the second of these by the first now gives a first order equation for $b(a)$. If $x = 4\pi\rho_0 r^2/3$, where ρ_0 is the density at $r = 0$, then the boundary condition near $r = 0$ ($x = 0$) is $a = x + \cdots$ and $b = 1 - 8x/5 + \cdots = 1 - 8a/5 + \cdots$. Phase plane analysis of this equation shows that there is a stable focus and saddle points. It is clear that $2a < 1$ always, ensuring that there is not a black hole event horizon outside the star. Numerical solution (done here with MAPLE) gives Fig. 1, where the focus is obvious.

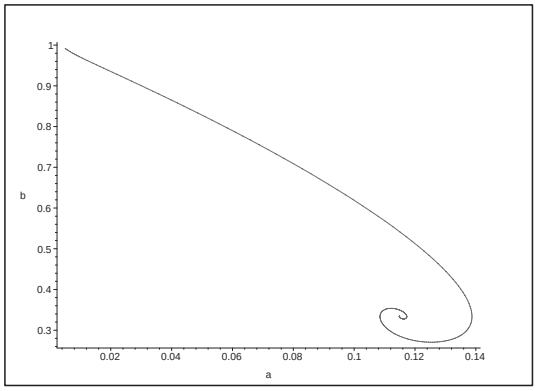

Figure 1. b vs. a for large density.

Density decreases as one moves out through the star and one must use a different equation of state, which means that the a–b trajectory must leave the focus and move down close to the a-axis, ending at the point where the pressure equals zero at the outer edge of the star. At that point one can determine the radius and mass of the star. But the oscillation at the focus is reflected in the final values. The total mass of the star is an oscillatory function of the central density and there is a maximum mass in the neighborhood of 1.4 solar masses, the Chandrasekhar limit. Thus for masses greater than that there will be collapse. There are two families of stable equilibria, white dwarfs and neutron stars, and this points the way toward the existence of collapsed configurations or black holes [2].

3 Axially symmetric configurations

For my second example, I consider stationary (rotating) axially symmetric fields, which include the Schwarzschild solution and the Kerr solution for a spinning point mass. The standard approach uses the metric

$$ds^2 = -f(dt + \omega d\phi)^2 + \rho^2 f^{-1} d\phi^2 + h f^{-1}\left(d\rho^2 + dz^2\right),$$

where f, ω, and h are functions of ρ and z. We can define a new, conjugate variable ψ, often called the twist potential, by (subscripts denote derivatives):

$$\omega_\rho = \rho f^{-2}\phi_z, \qquad \omega_z = -\rho f^{-2}\psi_\rho.$$

The field equations now are

$$\begin{aligned} f(f_{\rho\rho} + f_\rho/\rho + f_{zz}) &= f_\rho^2 + f_z^2 - \psi_\rho^2 - \psi_z^2, \\ f(\psi_{\rho\rho} + \psi_\rho/\rho + \psi_{zz}) &= 2f_\rho\psi_\rho + 2f_z\psi_z \end{aligned} \tag{3}$$

or, where $E = f + i\psi$ (the Ernst potential),

$$\Re(E)\nabla^2 E = (\nabla E)^2,$$

the Ernst equation. One can easily calculate the symmetries of equations (3). (Reference [3] has a similar calculation for the Einstein–Maxwell equations.) There are five symmetries: two on the independent variables alone,

$$\partial_z, \qquad \rho\partial_\rho + z\partial_z \tag{4}$$

and three on the dependent variables alone,

$$\partial_\psi, \qquad f\partial_f + \psi\partial_\psi, \qquad f\psi\partial_f + (1/2)\left(\psi^2 - f^2\right)\partial_\psi. \tag{5}$$

The symmetries (4), in particular the second (scale) symmetry, can be used to look for special solutions of the Ernst equation (which probably have little physical significance.) The symmetries (5), combined and exponentiated, yield the expression

$$E' = (aE + ib)/(icE + d)$$

the Ehlers transformation [4, 5], where a, b, c, and d are real constants. If E is a solution of the Ernst equation, then E' is also. Certain combinations of these variables and their derivatives are potentials for the Ernst equation. W. Kinnersley and his colleagues, through extensive research in the 1970s, pursued relations involving these potentials and higher symmetries of the Ernst equation in the jet space, eventually leading to a method of generating new solutions of the Ernst equation [6]. Alternate methods include the use of Bäcklund transformations, found by the present author and by G. Neugebauer [7, 8], and several other techniques found in the late 1970s.

4 Critical gravitational collapse

The third, and main, example is that of critical gravitational collapse. This work is still unfinished, but several interesting results have been obtained. About ten years ago M. Choptuik published a paper considering a massless scalar field in spherically symmetric gravity [9]. The aim was to investigate possible collapse to a black hole. He assumed a metric as follows:

$$ds^2 = -\alpha^2(r,t)dt^2 + a^2(r,t)dr^2 + r^2\left(d\theta^2 + \sin^2\theta d\phi^2\right),$$

with a time variable suitable near the origin $T_0 = \int_0^t \alpha(0,t)dt$. If $\phi(r,t)$ is the scalar field and where

$$\Phi = \phi_r, \qquad \Pi = a\phi_t/\alpha,$$

the Einstein equations are

$$\begin{aligned}
&\Phi_t = (\alpha\Pi/a)_r, \qquad \Pi_t = r^{-2}\left(r^2\alpha\Phi/a\right)_r, \\
&\alpha_r/\alpha - a_r/a + \left(1 - a^2\right)/r = 0, \\
&a_r/a + \left(a^2 - 1\right)/(2r) - 2\pi r\left(\Phi^2 + \Pi^2\right) = 0, \\
&a_t/\alpha = 4\pi r\Pi\Phi,
\end{aligned} \tag{6}$$

where subscripts denote derivatives. Choptuik does not use the last equation, since it is consistent with the others in the sense that calculation of the cross derivative of a from the last two equations, with use of the other equations, gives the same value. By analogy to the Schwarzschild case, he takes $a \to \infty$ to be the criterion for a black hole.

4.1 Results from numerical integration

Choptuik integrated the equations numerically, scaling the integration steps carefully, and found several interesting features. (1) For some values of a parameter p in the initial conditions for the scalar field black holes form, but for other values they do not. There is a critical parameter, p^*, for which black holes first form. (2) The precisely critical behavior, in which $p = p^*$, is *universal*, holding for all types of initial data. He uses variables $X = \sqrt{(2\pi)}r\Phi/a$, $Y = \sqrt{(2\pi)}r\Pi/a$, $\rho = \ln(kr)$, $\tau = \ln[k(T_0^* - T_0)]$, and finds the existence of the universal critical solution X^*, Y^*, which occurs in the neighborhood of $a = \infty$ and $r = 0$. (3) There is a scaling behavior. If $Z =$ either X or Y, then this is $Z^*(\rho-\Delta, \tau-\Delta) = Z^*(\rho, \tau)$, or $Z^*(\rho-\tau, \tau-\Delta) = Z^*(\rho-\tau, \tau)$. Thus there is a periodicity in τ with period Δ, where Δ is a universal constant, approximately equal to 3.43, independent of initial conditions. This indicates that the critical solution is somehow dependent only on the original equations, in which there is no natural length or time parameter; Δ thus should naturally come out of the equations. Furthermore, the mass M of the black hole is given by a power law $M = c|p - p^*|^\gamma$, where γ is another universal constant, approximately equal to 0.37, similar to critical phenomena in thermodynamics.

4.2 Symmetry treatment of equations

The scaling behavior suggests that an analytical approach, using scaled variables, might be useful. Choptuik already made the observation that the original equations (6) are invariant under the scaling $r \to kr$, $t \to kt$. We first define

$$A = \sqrt{(2\pi)}\Phi, \qquad B = \sqrt{(2\pi)}\Pi, \qquad C = \alpha/a, \qquad \sigma = \sqrt{(2\pi)}\phi, \qquad U = a^2.$$

Then the basic equations become

$$\begin{aligned} &A = \sigma_r, \qquad B = \sigma_t/C, \\ &A_t = (BC)_r, \qquad B_t = (AC)_r + 2AC/r, \qquad C_r/C = (U-1)/r, \\ &U_r/U + (U-1)/r = 2r\left(A^2 + B^2\right), \qquad U_t/U = 4rABC. \end{aligned} \tag{7}$$

We calculate the symmetries of equations (7) and find that the following are invariant variables: $\xi = rh(t)$, U, $F = rA$, $G = rB$, and $P = Ch^2/h'$, where $h(t)$ is an arbitrary function of t. In terms of Choptuik's variables, we have $F = aX$ and $G = aY$. We note that α^2, which is $-g_{00}$, is $(aC)^2$, which has a factor $\left(h'/h^2\right)^2$. So if we define a new time coordinate t_0 with $dt_0 = -h'dt/h^2$, we see that $h = 1/t_0$. We could make this definition of h, but it is more convenient to define it in terms of Choptuik's function $T_0(t)$ as $h^{-1}(t) = T_0^* - T_0(t)$, where the star indicates critical value. (This then gives the convenient boundary condition $aP = 1$ at r, or $\xi = 0$.) We now express the equations in terms of the variables $\xi = rh(t)$ and $v = t$. (We introduce a new name for t to avoid complications with partial derivative notation.) For any function H, we have $H_r = hH_\xi$ and $H_t = H_v + \xi(h'/h)H_\xi$. We also find it useful to define $P = -\xi Q$, $z = \ln\xi$, $\tau = \text{const} - \ln h$. We now note that τ is the same as Choptuik's τ and $z = \rho - \tau$, so we can look for the periodicity with period 3.43. In terms of derivatives with respect to z and τ (which do not appear explicitly), the equations take the following nice form

$$\begin{aligned} &F_\tau = (F + QG)_z, \qquad G_\tau = (G + QF)_z + 2QF, \qquad Q_z = Q(U-2), \\ &U_z/U = 2F^2 + 2G^2 + 1 - U, \qquad U_\tau/U = 4QFG + 2F^2 + 2G^2 + 1 - U. \end{aligned} \tag{8}$$

4.3 Approaches to solution

We now comment on several avenues of approach. (1) If we assume no τ dependence, then the last equation of (8) gives

$$U = 1 + 2F^2 + 2G^2 + 4QFG,$$

and the first equation gives

$$F = k - QG,$$

where k is a constant. The fourth equation is satisfied automatically. We get

$$Q_z = Q(U - 2)$$

and

$$G_z = Q\left(1 - Q^2\right)^{-1}[U(2QG - k) - 2QG]$$

so we can write an equation for $G(Q)$:

$$dG/dQ = \left(1 - Q^2\right)^{-1}(U - 2)^{-1}[U(2QG - k) - 2QG], \tag{9}$$

where U is given above in terms of G and Q. Equation (9) for $G(Q)$ can be put in various forms. However, I will not pursue those here, since we really want to search for the periodicity in τ.

In our search for periodic behavior in τ, we note that it can be exhibited either in linear equations resembling simple harmonic oscillator equations – which would have variable amplitude – or in nonlinear cases with a limit cycle. The nonlinear character of the equations suggests that the latter is the case; indeed, C. Gundlach in a review paper [10], sketches qualitative limit cycles – which, however, may actually change to nonperiodic behavior.

(2) In the Schwarzschild solution, $\alpha^2 = 1/a^2 = 1 - 2m/r$, for constant geometrized mass m. That suggests that near that solution, we might suspect that $\alpha \propto 1/a$, or that $C \propto \alpha/a \propto 1/a^2 = 1/U$. For U large, then, C (or P or Q) should be small. So let us consider an expansion of equations (8) in powers of Q. We first define $V = UQ$, which satisfies

$$V_z = V\left(2F^2 + 2G^2 - 1\right),$$

with

$$Q_z = V - 2Q.$$

We ignore the U_τ equation. Expand G, F, V:

$$G = a + bQ + \cdots, \qquad F = c + dQ + \cdots, \qquad V = f + gQ + \cdots,$$

where $a, b, \ldots, g$ are functions of τ. We get, from the expansion,

$$\dot{c} = f(a + d), \qquad \dot{d} = (a + d)(g - 2), \qquad \dot{a} = f(b + c),$$
$$\dot{b} = (b + c)(g - 2) + 2c, \qquad g = 2a^2 + 2c^2 - 1,$$

where the dot represents differentiation with respect to τ. There is another equation for g which we ignore. We will also assume f to be a constant. We solve the first and third equations for d and b and substitute them and g into the second and fourth equations. We get

$$\ddot{a} = \dot{a}\left(2a^2 + 2c^2 - 3\right) + f(\dot{c} + 2c),$$
$$\ddot{c} = \dot{c}\left(2a^2 + 2c^2 - 3\right) + f\dot{a}.$$

We integrate these with MAPLE. For $f = 20$, we get oscillatory behavior with a period of about 2.5, but not a perfect limit cycle in a and c (Fig. 2). For $f = 200$, we are closer (Fig. 3). For $f = 225$, we get what appears to be a perfect limit cycle, with period about 1.8 (Figs. 4 and 5).

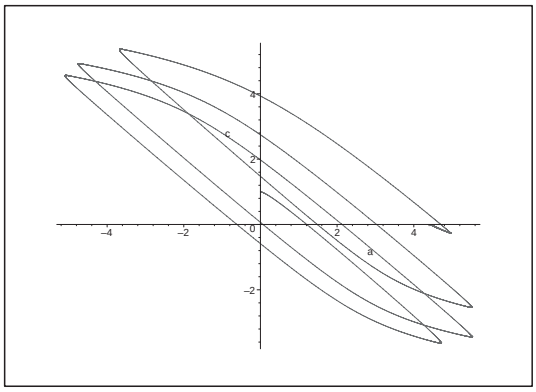

Figure 2. c vs. a for $f = 20$.

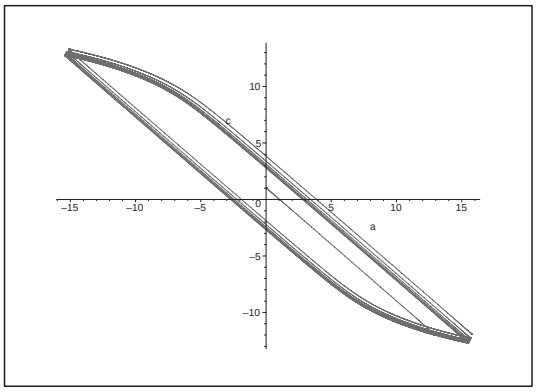

Figure 3. c vs. a for $f = 200$.

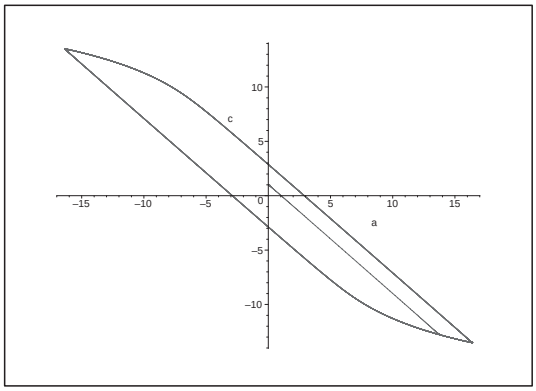

Figure 4. c vs. a for $f = 225$.

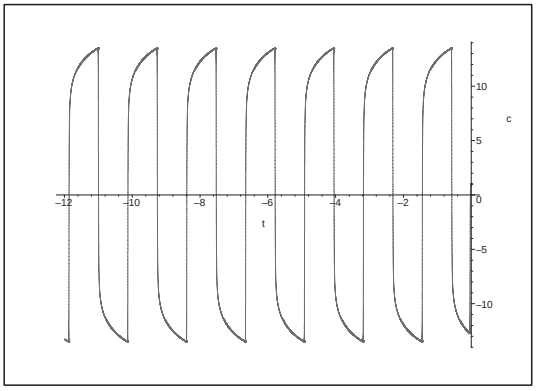

Figure 5. c vs. τ (shown as t) for $f = 225$.

There are several problems associated with this calculation. We ignored the U_τ equation. A closely related matter is that we ignored any τ dependence in Q. We also ignored the second equation for g, which appears to be inconsistent with other equations, and we assumed f to be constant. There is no particular obvious reason why the value of 225 for f should be special, and the period obtained is not 3.4 but is roughly half that. Nevertheless, the periodic behavior of a and c strongly suggests that we may be on the right track.

(3) In order to clear up some of the problems of the last treatment, we take our functions F, etc., to be functions of $Q(z, \tau)$ and v $(= \tau)$. Then for any function H, we have $H_z = H_Q Q_z = H_Q Q(U - 2)$ and $H_\tau = H_Q Q_\tau + H_v$. If we put

$$\beta = 2F^2 + 2G^2 + 1 - U,$$

then from the U equations we can find

$$U_Q = \beta U/[Q(U - 2)]$$

and

$$Q_\tau = Q(U - 2)(4QFG + \beta - U_v/U)/\beta.$$

We substitute for Q_τ in the two equations for F and G and get rather messy equations involving Q, F, G, and the derivatives of F and G with respect to v and Q. We expand F and G in powers of Q, with coefficients as functions of v. We write

$$U = a/Q + b + \cdots, \qquad F = d + eQ + \cdots, \qquad G = h + mQ + \cdots.$$

We find, where the dot indicates $d/dv = d/d\tau$,

$$b = 2d^2 + 2h^2 - 1, \qquad \dot{d} = ha, \qquad \dot{h} = da,$$

and equations for e and m,

$$a\dot{e} + e\dot{a} = ha(b-2) + 2ma^2,$$
$$a\dot{m} + m\dot{a} = dab + 2ea^2.$$

Thus d, for example, obeys

$$\ddot{d} - \dot{a}\dot{d}/a - a^2 d = 0,$$

indicating exponential instead of oscillatory behavior. Inspection of the equations indicates that the change results precisely from the inclusion of Q_τ.

(4) We now note that it is more natural to consider an expansion in $1/U$ than in Q, since U is the variable considered to be large near a black hole. Furthermore, it is very convenient to do so since we have expressions for both U_z and U_τ (8). For any $H(z,\tau)$, we convert it to $H(U,v)$, where $v = \tau$. This gives

$$H_z = H_U U_z = H_U U\left(2F^2 + 2G^2 + 1 - U\right)$$

and

$$H_\tau = H_v + H_U U_\tau = H_v + H_U U\left(4QFG + 2F^2 + 2G^2 + 1 - U\right).$$

The equation for Q_z now becomes

$$Q_U U\left(2F^2 + 2G^2 + 1 - U\right) = Q(U-2).$$

This expression can be used to replace Q_U in the F and G equations when it occurs. Those equations now become

$$F_v + 4QUFGF_U = QU\left(2F^2 + 2G^2 + 1 - U\right)G_U + QG(U-2),$$
$$G_v + 4QUFGG_\tau = QU\left(2F^2 + 2G^2 + 1 - U\right)F_U + QFU.$$

It will be noted that Q appears as a multiplier in all terms except the v derivatives, and U appears in most terms. We define $R = QU$ and rewrite the equations as

$$R_U/R = \left(2F^2 + 2G^2 - 1\right)/[U\left(2F^2 + 2G^2 + 1 - U\right)],$$
$$F_v/R = \left(2F^2 + 2G^2 + 1 - U\right)G_U - 4FGF_U + G(1 - 2/U),$$
$$G_v/R = \left(2F^2 + 2G^2 + 1 - U\right)F_U - 4FGG_U + F.$$

We see that the integration of the first equation gives an additive function $\ln b(v)$ in $\ln R$, or a multiplicative function $b(v)$ in R. This can be removed in the second and third equations simply by redefining the time variable as $w = \int b(v)dv$. This removes the ambiguity in the v $(= \tau)$ dependence of Q $(= R/U)$. Inspection now shows that it is advantageous to define $x = F + G$ and $y = F - G$. The equations are now simplified to

$$R_U/R = \left(x^2 + y^2 - 1\right)/[U\left(x^2 + y^2 + 1 - U\right)],$$
$$x_v/R = 2y^2 x_U + (1-U)\left(x_U - x/U\right) + y/U, \tag{10}$$
$$y_v/R = -2x^2 y_U - (1-U)\left(y_U - y/U\right) - x/U.$$

These are still exact. If they could be solved, then x, y, and R could be substituted into the U_z equation to find the z dependence of U, then the τ $(= v)$ dependence could be found from the U_τ equation. The obvious approach now is to expand in powers of $1/U$. Unfortunately, this does not give oscillatory behavior for x and y, but exponential behavior instead, just as in the expansion for small Q. Variations of approach do not solve the problem. It may be that we have an essential singularity, or to say it another way, that we should assume x and y involve, say, $\exp(-U)$. It is not clear how to investigate this possibility.

We try to solve the x and y equations (10) by a brute force approach. We assume

$$x = \phi(w)S(U), \qquad y = \psi(w)Y(U),$$

substitute into (10), and assume that ϕ and ψ satisfy equations that are purely functions of w, as follows (prime indicates d/dw):

$$\phi' = a\psi^2\phi + b\phi + c\psi,$$
$$\psi' = d\phi^2\psi + f\psi + g\phi,$$

where a, b, c, d, f, g are constants. We substitute these equations into (10) and equate coefficients, thus obtaining six equations for the two functions S and Y. If we assume $x^2 + y^2$ large, we get $R = U$, and then we find some consistency in these six equations, provided that $Y = cS$, $gc = -1$, $a = -dc^2$, and $f = -b$. If we solve for d, f, and g and substitute in the second equation, we find

$$\psi' = -(a/c^2)\phi^2\psi - b\psi - \phi/c.$$

If we let $\phi = c/\sqrt{a}\phi_0$ and $\psi = 1/\sqrt{a}\psi_0$, we see that we may scale a and c away. So just put $a = c = 1$, and we get

$$\phi' = \psi^2\phi + b\phi + \psi,$$
$$\psi' = -\phi^2\psi - b\psi - \phi. \tag{11}$$

We get inconsistent equations for $S(U)$. One of these is

$$S_U/S = (1 - U + b)/[U(1 - U)],$$

yielding

$$S = kU[U/(U - 1)]^b$$

for some constant k. The other is

$$2SS_U = 1/U,$$

yielding $S^2 = \ln U +$ const. We ignore the second equation and note that for large U, the first gives approximately $S = kU$.

We explore the ϕ, ψ equations (11). In the phase plane of ϕ and ψ the origin is a critical point, a center. We can actually solve (11) in the phase plane exactly, finding

$$\phi^2 + \psi^2 + 2b\ln(1 + \phi\psi) = \lambda^2,$$

where λ is a constant. If $b = 0$ this is exactly a circle. Integration of the time equations (Figs. 6, 7) shows that we get oscillations in w and a limit cycle, which is nearly circular for small b. λ measures the amplitude. For small b and $\lambda = 1$ (fixed by the initial conditions), the period is about 7.2. Calculation from the exact solution indicates that the period should

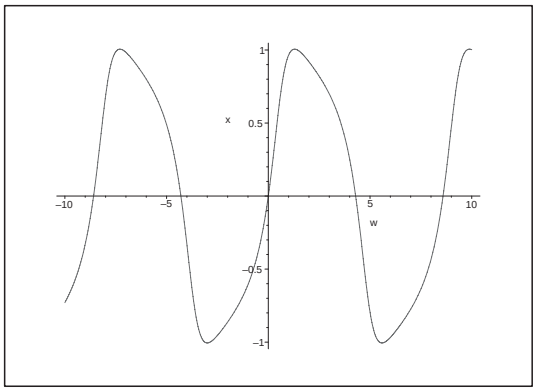

Figure 6. ϕ (shown as x) vs. t for $b = 0.1$.

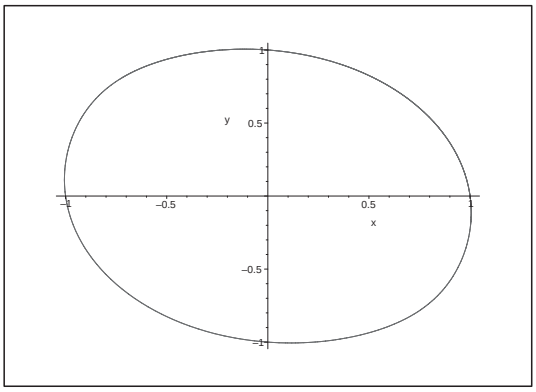

Figure 7. ψ (shown as y) vs. ϕ (shown as x) for $b = 0.1$.

be about 2π. The cubic terms in (10) appear to be proportional to both U and λ, suggesting that λ scales with $1/U$. These oscillations are for constant U. We really want constant z, the original scaled variable. Attempts to include the time dependence of U produce the exponential behavior seen before.

Another approach proceeds as follows. Let x and y in equation (10) be functions of w only and write, temporarily, $\alpha = x^2 + y^2$. Treat α as a constant and integrate the R equation. We get, exactly,

$$R = (1 - (\alpha + 1)/U)^{\beta},$$

where

$$\beta = (1 - \alpha)/(1 + \alpha).$$

Expansion for large U gives approximately

$$R = 1 + (\alpha - 1)/U.$$

Put $1/U = b$, which is now to be treated as a parameter, and put this into the x and y equations in (10) along with the expression for α, keep terms of order b, and get:

$$x_w = x + b\left[\left(x^2 + y^2 - 2\right) + y\right],$$
$$y_w = -y - b\left[\left(x^2 + y^2 - 2\right) + x\right].$$

These equations have interesting behavior. If $x^2 + y^2$ is small, the equations may be treated as linear. We find then that the origin in (x, y) phase space is a center if $1 > b > 1/3$. In that region, if we start with small x and y they remain small and we get linear equations, with period depending on b, and arbitrary amplitude. For $b > 1$, x and y grow and we get a nonlinear oscillation. For large enough b, the period is approximately proportional to $15/b$ and the maximum amplitude of x and y is unity (Figs. 8, 9).

Instead of using the approximate value of R, we can use the exact value (being careful to take the absolute value of the quantity in parentheses before raising to the power. Then

$$x_w = R[x + b(y - x)],$$
$$y_w = -R[y + b(x - y)].$$

Integration of these equations gives some very nice limit cycles, but the period varies with the choice of b and of the initial conditions (Figs. 10–12).

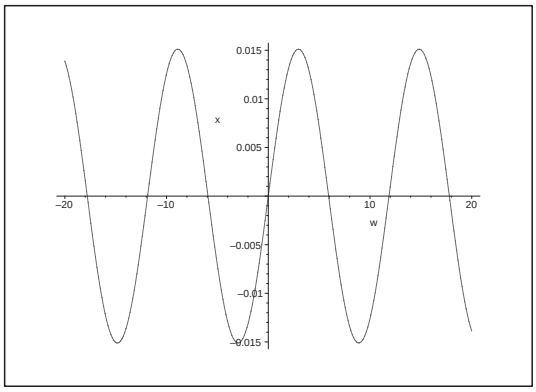

Figure 8. x vs. w, $b = 0.8$, approximate R.

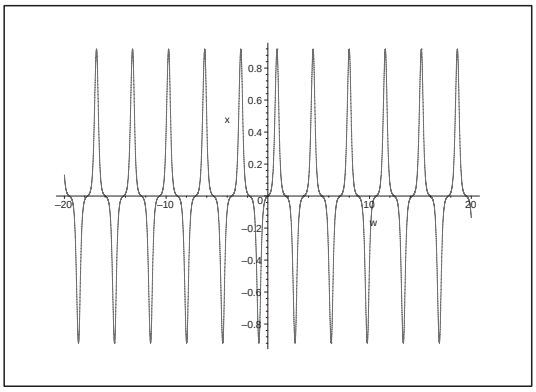

Figure 9. x vs. w, $b = 5$, approximate R.

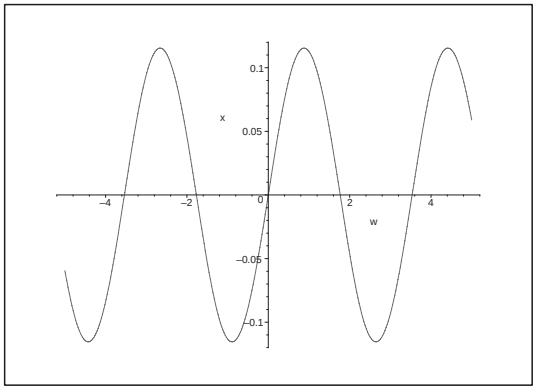

Figure 10. x vs. w, $b = 2$, $y_0 = 0.1$, exact R.

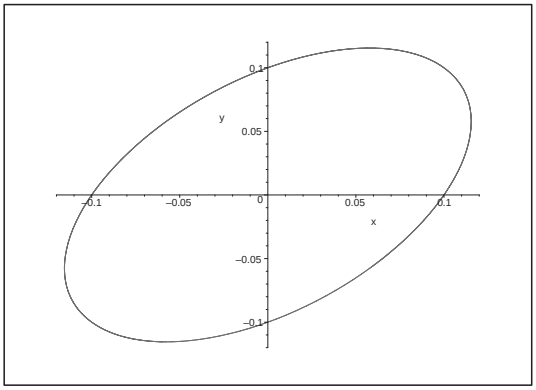

Figure 11. y vs. x, $b = 2$, $y_0 = 0.1$, exact R.

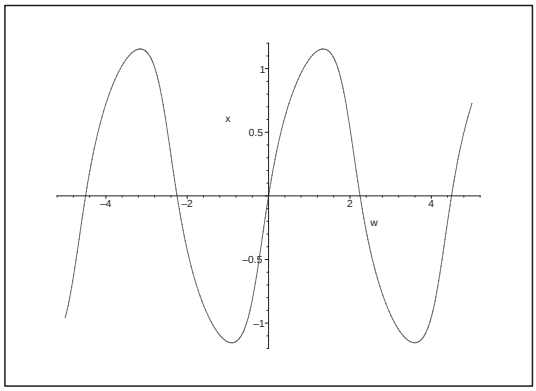

Figure 12. x vs. w, $b = 2$, $y_0 = 1$, exact R.

4.4 Summary of results

In summary, we note several features in this treatment. First, the original equations have been expressed with τ and the scaled variable z as independent variables. Second, in the τ-independent case, the equations may be reduced to a single first order equation. The significance of this case is still unclear. Third, changing the independent variables to $w\ (= \tau)$ and U separates the equations into three equations for R, x, and y and two for the derivatives of U – a convenient form. Fourth, oscillatory behavior is suggested in four different ways. The amplitude in these may scale as $1/U$. Each way has unacceptable assumptions. Trying to remove the assumptions produces exponential behavior. It may be that, as indicated by Gundlach [10] and as mentioned

earlier, there is an epoch of oscillation followed by an epoch of final nonoscillatory behavior, which might be exponential. One would think, however, that there still should be a way of finding the period $\Delta = 3.43$ analytically. This has not yet been done successfully.

In the spirit of the recent work of Ibragimov [1] who adopted the infinitesimal method for calculating invariants of families of differential equations using the equivalence groups, we apply the method to evolution type equations of the form $u_t = f(x,u)u_{xx} + g(x,u,u_x)$. We show that the equivalence Lie algebra admitted by this equation has two functionally independent differential invariants of the second order.

1 Introduction

We consider evolution equations of the form

$$u_t = f(x,u)u_{xx} + g(x,u,u_x). \tag{1}$$

A number of many special cases in this class of equations have been successfully used to model physical problems. Such example is the nonlinear diffusion equation $u_t = [D(u)u_x]_x$. Group properties of this equation were studied by Ovsiannikov [2]. Other examples of such equations that appear in the literature are $u_t = [g(x)D(u)u_x]_x$, $u_t = [g(x)D(u)u_x]_x - K(u)u_x$, $u_t = (u^n)_{xx} + g(x)u^m + f(x)u^s u_x$, etc.

It can be shown that equations (1) admit equivalence transformation

$$x' = P(x), \qquad t' = c_1 t + c_2, \qquad u' = R(x,u) \tag{2}$$

with

$$f' = \frac{P_x^2 f}{c_1}, \qquad g' = \frac{P_x R_u g + (P_{xx}R_u u_x + P_{xx}R_x - 2P_x R_{ux}u_x - P_x R_{uu}u_x^2 - P_x R_{xx})f}{c_1 P_x}.$$

If we set $P(x) = x + \epsilon\phi(x)$ and $R(x,u) = u + \epsilon\psi(x,u)$, we can write the above transformations in infinitesimal form. That is, in the form

$$Y = \xi^1\frac{\partial}{\partial t} + \xi^2\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial u} + \zeta\frac{\partial}{\partial u_x} + \mu\frac{\partial}{\partial f} + \nu\frac{\partial}{\partial g}, \tag{3}$$

where ξ^1, ξ^2 and η depend on t, x and u, while μ and ν depend on t, x, u, u_x, f and g, and ζ is given by $\zeta = D_x(\eta) - u_t D_x(\xi^1) - u_x D_x(\xi^2)$. The operator D_x is the total derivative with respect to x.

We deduce that the class of equations (1) has an infinite continuous group of equivalence transformations generated by the infinite-dimensional Lie algebra which is spanned by the ope-

rators:

$$Y_1 = \frac{\partial}{\partial t}, \qquad Y_2 = t\frac{\partial}{\partial t} - f\frac{\partial}{\partial f} - g\frac{\partial}{\partial g},$$
$$Y_\phi = \phi(x)\frac{\partial}{\partial x} - \phi' u_x \frac{\partial}{\partial u_x} + 2\phi' f\frac{\partial}{\partial f} + \phi'' f u_x \frac{\partial}{\partial g},$$
$$Y_\psi = \psi(x,u)\frac{\partial}{\partial u} + (\psi_x + \psi_u u_x)\frac{\partial}{\partial u_x} + \left[\psi_u g - (\psi_{uu}u_x^2 + 2\psi_{xu}u_x + \psi_{xx})f\right]\frac{\partial}{\partial g}. \tag{4}$$

In this paper we calculate differential invariants of equivalence transformations of equations (1) by using the infinitesimal method for calculations of invariants of families of equations developed in [3]. In the following three sections we consider the problem of classifying differential invariants of equations (1) of zero, first and second order.

2 Differential invariants of order zero

We search for invariants of order zero. That is, invariants of the form

$$J = J(t, x, u, u_x, f, g).$$

We apply the invariant test $Y(J) = 0$ to the operators Y_1, Y_2, Y_ϕ and Y_ψ and using the fact that $\phi(x)$ and $\psi(x,u)$ are arbitrary functions, we obtain $J = \text{const}$. Hence, equations (1) do not admit differential invariants of order zero.

3 Differential invariants of first order

In order to determine differential invariants of the first order,

$$J = J(t, x, u, u_x, f, g, f_x, f_u, g_x, g_u, g_{u_x})$$

we need to consider the first prolongation of Y,

$$Y^{(1)} = Y + \mu^x\frac{\partial}{\partial f_x} + \mu^u\frac{\partial}{\partial f_u} + \nu^x\frac{\partial}{\partial g_x} + \nu^u\frac{\partial}{\partial g_u} + \nu^{u_x}\frac{\partial}{\partial g_{u_x}},$$

where

$$\mu^k = \tilde{D}_k(\mu) - f_x\tilde{D}_k(\xi^2) - f_u\tilde{D}_k(\eta), \qquad k = x,\ u,$$
$$\nu^k = \tilde{D}_k(\nu) - g_x\tilde{D}_k(\xi^2) - g_u\tilde{D}_k(\eta) - g_{u_x}\tilde{D}_k(\zeta), \qquad k = x,\ u,\ u_x, \tag{5}$$

where $\tilde{D}_x$, $\tilde{D}_u$ and $\tilde{D}_{u_x}$ denote the total derivatives with respect to x, u and u_x:

$$\tilde{D}_x = \frac{\partial}{\partial x} + f_x\frac{\partial}{\partial f} + g_x\frac{\partial}{\partial g} + f_{xx}\frac{\partial}{\partial f_x} + f_{xu}\frac{\partial}{\partial f_u} + g_{xx}\frac{\partial}{\partial g_x} + g_{xu}\frac{\partial}{\partial g_u} + g_{xu_x}\frac{\partial}{\partial g_{u_x}} + \cdots,$$
$$\tilde{D}_u = \frac{\partial}{\partial u} + f_u\frac{\partial}{\partial f} + g_u\frac{\partial}{\partial g} + f_{xu}\frac{\partial}{\partial f_x} + f_{uu}\frac{\partial}{\partial f_u} + g_{xu}\frac{\partial}{\partial g_x} + g_{uu}\frac{\partial}{\partial g_u} + g_{uu_x}\frac{\partial}{\partial g_{u_x}} + \cdots,$$
$$\tilde{D}_{u_x} = \frac{\partial}{\partial u_x} + f_{u_x}\frac{\partial}{\partial f} + g_{u_x}\frac{\partial}{\partial g} + f_{xu_x}\frac{\partial}{\partial f_x} + f_{uu_x}\frac{\partial}{\partial f_u} + g_{xu_x}\frac{\partial}{\partial g_x} + g_{uu_x}\frac{\partial}{\partial g_u} + g_{u_xu_x}\frac{\partial}{\partial g_{u_x}} + \cdots. \tag{6}$$

Using the formulae (5) and (6) we obtain the first extension of the generators Y_1, Y_2, Y_ϕ, Y_ψ given by equations (4):

$$
\begin{aligned}
&Y_1^{(1)} = Y_1, \qquad Y_2^{(1)} = Y_2 - f_x\frac{\partial}{\partial f_x} - f_u\frac{\partial}{\partial f_u} - g_x\frac{\partial}{\partial g_x} - g_u\frac{\partial}{\partial g_u} - g_{u_x}\frac{\partial}{\partial g_{u_x}},\\
&Y_\phi^{(1)} = Y_\phi + (2\phi''f + \phi' f_x)\frac{\partial}{\partial f_x} + 2\phi' f_u\frac{\partial}{\partial f_u}\\
&\qquad + (u_x\phi'''f + u_x\phi'' f_x - g_x\phi' + \phi'' u_x g_{u_x})\frac{\partial}{\partial g_x} + u_x\phi'' f_u\frac{\partial}{\partial g_u} + (\phi'' f + \phi' g_{u_x})\frac{\partial}{\partial g_{u_x}},\\
&Y_\psi^{(1)} = Y_\psi - f_u\psi_x\frac{\partial}{\partial f_x} - f_u\psi_u\frac{\partial}{\partial f_u} + [\psi_{xu} - (\psi_{xuu}u_x^2 + 2\psi_{xxu}u_x + \psi_{xxx})f\\
&\qquad - (\psi_{uu}u_x^2 + 2\psi_{xu}u_x + \psi_{xx})f_x + \psi_u g_x - \psi_x g_u - (\psi_{xx} + \psi_{xu}u_x)g_{u_x}]\frac{\partial}{\partial g_x}\\
&\qquad + [\psi_{uu}g - (\psi_{uuu}u_x^2 + 2\psi_{xuu}u_x + \psi_{xxu}) - (\psi_{uu}u_x^2 + 2\psi xuu_x + \psi_{xx})f_u\\
&\qquad - (\psi_{uu}u_x + \psi_{xu})g_{u_x}]\frac{\partial}{\partial g_u} - 2(\psi_{uu}u_x + \psi_{xu})f\frac{\partial}{\partial g_{u_x}}. \qquad (7)
\end{aligned}
$$

We note that $Y_1^{(n)} = Y_1$. Hence for any order of differential invariants $J_t = 0$.

Now from the differential invariant test $Y^{(1)}(J) = 0$, we get three identities

$$E_2 = Y_2^{(1)}(J) = 0, \qquad E_\phi = Y_\phi^{(1)}(J) = 0, \qquad E_\psi = Y_\psi^{(1)}(J) = 0. \qquad (8)$$

Since $\phi(x)$ and $\psi(x,u)$ are arbitrary functions, coefficients of ϕ in $E_\phi = 0$ and ψ in $E_\psi = 0$ give $J_x = J_u = 0$. Now coefficients of ψ_{uuu}, ψ_{xuu}, ψ_{uu} and ψ_{xu} give $J_{g_u} = J_{g_x} = J_g = J_{g_{u_x}} = 0$. Coefficient of ϕ'' in $E_\phi = 0$ gives $J_{f_x} = 0$ and coefficient of ψ_x in $E_\psi = 0$ gives $J_{u_x} = 0$. Hence, $J = J(f, f_u)$ and equations (8) read

$$E_1 = -\left(f\frac{\partial J}{\partial f} + f_u\frac{\partial J}{\partial f_u}\right) = 0, \qquad E_\phi = 2\left(f\frac{\partial J}{\partial f} + f_u\frac{\partial J}{\partial f_u}\right)\phi' = 0, \qquad E_\psi = f_u\frac{\partial J}{\partial f_u}\psi_u = 0.$$

If $f_u \neq 0$ from the above relations we deduce that $J_{f_u} = J_f = 0$ and therefore equations (1) do not admit differential invariant of the first order. However the equation

$$f_u = 0 \qquad (9)$$

is invariant under the group which is spanned by (7). That is,

$$Y_1^{(1)}(f_u)|_{f_u=0} = 0, \qquad Y_2^{(1)}(f_u)|_{f_u=0} = 0, \qquad Y_\phi^{(1)}(f_u)|_{f_u=0} = 0, \qquad Y_\psi^{(1)}(f_u)|_{f_u=0} = 0.$$

4 Differential invariants of second order

Now we determine differential invariants that depend on the second derivatives of f and g. Here we need to calculate the second prolongation of (4). As in the previous case it is straightforward to deduce that $J_t = J_x = J_u = 0$. Hence,

$$J = J(u_x, f, g, f_x, f_u, g_x, g_u, g_{u_x}, f_{xx}, f_{xu}, f_{uu}, g_{xx}, g_{xu}, g_{xu_x}, g_{uu}, g_{uu_x}, g_{u_x u_x}).$$

Now the second prolongation of (4) reads

$$
\begin{aligned}
Y_2^{(2)} &= Y_2^{(1)} - f_{xx}\frac{\partial}{\partial f_{xx}} - f_{xu}\frac{\partial}{\partial f_{xu}} - f_{uu}\frac{\partial}{\partial f_{uu}} - g_{xx}\frac{\partial}{\partial g_{xx}} - g_{xu}\frac{\partial}{\partial g_{xu}} - g_{xu_x}\frac{\partial}{\partial g_{xu_x}} \\
&\quad - g_{uu}\frac{\partial}{\partial g_{uu}} - g_{uu_x}\frac{\partial}{\partial g_{uu_x}} - g_{u_xu_x}\frac{\partial}{\partial g_{u_xu_x}}, \\
Y_\phi^{(2)} &= Y_\phi^{(1)} + (2\phi'''f + 3\phi''f_x)\frac{\partial}{\partial f_{xx}} + (2\phi''f_u + \phi' f_{xu})\frac{\partial}{\partial f_{xu}} + 2\phi' f_{uu}\frac{\partial}{\partial f_{uu}} \\
&\quad + (u_x\phi^{(iv)}f + \cdots)\frac{\partial}{\partial g_{xx}} + (u_x\phi'''f_u + \cdots)\frac{\partial}{\partial g_{xu}} \\
&\quad + (\phi'''f + \phi''g_{u_x} + \phi''f_x + u_x\phi''g_{u_xu_x})\frac{\partial}{\partial g_{xu_x}} + u_x\phi''f_{uu}\frac{\partial}{\partial g_{uu}} \\
&\quad + (\phi''f_u + \phi' g_{uu_x})\frac{\partial}{\partial g_{uu_x}} + 2\phi' g_{u_xu_x}\frac{\partial}{\partial g_{u_xu_x}}, \\
Y_\psi^{(2)} &= Y_\psi^{(1)} - (\psi_{xu}f_u + 2\psi_x f_{xu})\frac{\partial}{\partial f_{xx}} - (\psi_{xu}f_u + \psi_u f_{xu} + \psi_x f_{uu})\frac{\partial}{\partial f_{xu}} \\
&\quad - (f_u\psi_{uu} + 2f_{uu}\psi_u)\frac{\partial}{\partial f_{uu}} + (-\psi_{xxxx}f + \cdots)\frac{\partial}{\partial g_{xx}} + (-\psi_{xxxu}f + \cdots)\frac{\partial}{\partial g_{xu}} \\
&\quad + (-\psi_{uuuu}fu_x^2 + \cdots)\frac{\partial}{\partial g_{uu}} - [2\psi_{xuu}u_xf + 2\psi_{xxu}f + 2\psi_{uu}f_xu_x + 2\psi_{xu}f_x + \psi_x g_{uu_x} \\
&\quad + (\psi_{xx} + \psi_{xu}u_x)g_{u_xu_x}]\frac{\partial}{\partial g_{xu_x}} - [2\psi_{uuu}u_xf + 2\psi_{xuu}f + 2\psi_{uu}f_uu_x + 2\psi_{xu}f_u \\
&\quad + \psi_u g_{uu_x} + (\psi_{xu} + \psi_{uu}u_x)g_{u_xu_x}]\frac{\partial}{\partial g_{uu_x}} - (2\psi_{uu}f + \psi_u g_{u_xu_x})\frac{\partial}{\partial g_{u_xu_x}}. \qquad (10)
\end{aligned}
$$

The invariant test produces three identities

$$
E_2 = Y_2^{(2)}(J) = 0, \qquad E_\phi = Y_\phi^{(2)}(J) = 0, \qquad E_\psi = Y_\psi^{(2)}(J) = 0. \qquad (11)
$$

Coefficients of ψ_{xxxx}, ψ_{xxxu}, ψ_{uuuu} and ψ_{xxx} in $E_\psi = 0$ give $J_{g_{xx}} = J_{g_{xu}} = J_{g_{uu}} = J_{g_x} = 0$. Hence,

$$
J = J(u_x, f, g, f_x, f_u, g_u, g_{u_x}, f_{xx}, f_{xu}, f_{uu}, g_{xu_x}, g_{uu_x}, g_{u_xu_x}).
$$

Equation $E_2 = 0$ now reads

$$
\begin{aligned}
&fJ_f + gJ_g + f_xJ_{f_x} + f_uJ_{f_u} + g_uJ_{g_u} + g_{u_x}J_{g_{u_x}} + f_{xx}J_{f_{xx}} + f_{xu}J_{f_{xu}} + f_{uu}J_{f_{uu}} \\
&\quad + g_{xu_x}J_{g_{xu_x}} + g_{uu_x}J_{g_{uu_x}} + g_{u_xu_x}J_{g_{u_xu_x}} = 0.
\end{aligned}
$$

From this first order partial differential equation we get 12 integrals

$$
\begin{aligned}
&p_1 = \frac{f}{g}, \quad p_2 = \frac{f_x}{f}, \quad p_3 = \frac{f_u}{f}, \quad p_4 = \frac{g_u}{g}, \quad p_5 = \frac{g_{u_x}}{g}, \quad p_6 = \frac{f_{xx}}{f}, \\
&p_7 = \frac{f_{xu}}{f}, \quad p_8 = \frac{f_{uu}}{f}, \quad p_9 = \frac{g_{xu_x}}{g}, \quad p_{10} = \frac{g_{uu_x}}{g}, \quad p_{11} = \frac{g_{u_xu_x}}{g}, \quad p_{12} = u_x. \qquad (12)
\end{aligned}
$$

Coefficient of ψ_{xxu} in $E_\psi = 0$ gives

$$
J_{p_4} + 2J_{p_9} = 0,
$$

where we have used the new variables p_i. The above relation reduces the integrals by one:

$$
p_1, \quad p_2, \quad p_3, \quad p_5, \quad p_6, \quad p_7, \quad p_8, \quad p_{10}, \quad p_{11}, \quad p_{12}, \quad q_4 = 2p_4 - p_9. \qquad (13)
$$

From the coefficient of ψ_{xuu} in $E_\psi = 0$ we get

$$J_{p_{10}} + p_{12} J_{q_4} = 0$$

and therefore we have the following 10 integrals

$$p_1, \quad p_2, \quad p_3, \quad p_5, \quad p_6, \quad p_7, \quad p_8, \quad p_{11}, \quad p_{12}, \quad r_4 = q_4 - p_{12} p_{10}. \tag{14}$$

Coefficient of ψ_x in $E_\psi = 0$ gives

$$J_{p_{12}} - p_3 J_{p_2} - 2p_7 J_{p_6} - p_8 J_{p_7} = 0$$

which produces the integrals

$$p_1, \quad p_3, \quad p_5, \quad p_8, \quad p_{11}, \quad r_4, \quad q_2 = p_2 + p_3 p_{12}, \quad q_6 = p_7^2 - p_6 p_8, \quad q_7 = p_7 + p_8 p_{12}. \tag{15}$$

Coefficient of ψ_{xx} in $E_\psi = 0$ produces

$$p_1^2 J_{p_1} + p_1 p_{11} J_{p_{11}} + p_1 p_5 J_{p_5} + p_3 p_8 J_{q_6} + (p_{11} + p_1 r_4 - 2p_1 p_3) J_{r_4} = 0$$

which implies the integrals

$$p_3, \quad p_8, \quad q_2, \quad q_7, \quad q_5 = \frac{p_5}{p_1}, \quad q_{11} = \frac{p_{11}}{p_1}, \quad r_6 = q_6 + \frac{p_3 p_8}{p_1}, \quad \mu_4 = \frac{r_4}{p_1} + \frac{p_{11}}{p_1^2} - 2\frac{p_3}{p_1}. \tag{16}$$

We take the coefficient of ψ_{xu} in $E_\psi = 0$,

$$2J_{q_5} + p_3 J_{q_7} + 2p_3 q_7 J_{r_6} + 2(q_5 - q_2) J_{\mu_4} = 0.$$

We obtain the integrals

$$p_3, \quad p_8, \quad q_2, \quad q_{11}, \quad r_5 = q_5^2 - 2q_2 q_5 - 2\mu_4, \quad r_7 = 2q_7 - p_3 q_5, \quad \mu_6 = q_7^2 - r_6. \tag{17}$$

Coefficient of ψ_{uu} in $E_\psi = 0$ gives

$$p_3 \mu_6 J_{\mu_6} + 2p_8 J_{q_{11}} + p_3 p_8 J_{p_8} = 0$$

which produces the integrals

$$p_3, \quad q_2, \quad r_5, \quad r_7, \quad r_{11} = p_3 q_{11} - 2p_8, \quad \lambda_6 = \frac{\mu_6}{p_8}. \tag{18}$$

Coefficient of ψ_u in $E_\psi = 0$ gives the equation

$$p_3 J_{p_3} + 2r_{11} J_{r_{11}} + r_7 J_{r_7} = 0$$

from which we get the solutions

$$q_2, \quad r_5, \quad \lambda_6, \quad \mu_7 = \frac{r_7}{p_3}, \quad \mu_{11} = \frac{r_{11}}{p_3^2}. \tag{19}$$

Solutions (19) satisfy $E_\psi = 0$ for any arbitrary function $\psi(x, u)$. Now we use the identity $E_\phi = 0$. Coefficient of ϕ''' gives

$$J_{r_5} + J_{\lambda_6} = 0$$

and therefore we have

$$q_2, \quad \mu_7, \quad \mu_{11}, \quad \mu_5 = r_5 - \lambda_6. \tag{20}$$

Coefficient of ϕ'' in $E_\phi = 0$ produces the equation

$$2J_{q_2} + 3J_{\mu_7} - 3q_2 J_{\mu_5} = 0$$

which gives the integrals

$$\mu_{11}, \quad \lambda_7 = 2\mu_7 - 3q_2, \quad \lambda_5 = 4\mu_5 + 3q_2^2. \tag{21}$$

Finally equation $E_\phi = 0$ reads

$$(2\lambda_5 J_{\lambda_5} + \lambda_7 J_{\lambda_7})\phi' = 0.$$

Hence we obtain the solutions

$$J_1 = \mu_{11}, \qquad J_2 = \frac{\lambda_5}{\lambda_7^2}. \tag{22}$$

Now, using the sequence of integrals (12)–(22), we can write the forms of J_1 and J_2 in terms of the original variables, u_x, f, g, f_x, f_u, g_u, g_{u_x}, f_{xx}, f_{xu}, f_{uu}, g_{xu_x}, g_{uu_x}, $g_{u_xu_x}$. We therefore conclude that equation (1) has two invariants of the second order:

$$J_1 = \frac{f_u g_{u_xu_x} - 2ff_{uu}}{f_u^2}, \tag{23}$$

$$\begin{aligned} J_2 = f_u^2(&-4u_x^2 ff_{uu} - 8u_x ff_{xu} - 4ff_{xx} - 16fg_u \\ &+ 8u_x fg_{uu_x} + 8fg_{xu_x} + 3u_x^2 f_u^2 + 6u_x f_x f_u + 20gf_u - 8u_x f_u g_{u_x} + 3f_x^2 - 8f_x g_{u_x} \\ &- 8gg_{u_xu_x} + 4g_{u_x}^2)/(4u_x ff_{uu} + 4ff_{xu} - 3u_x f_u^2 - 3f_x f_u - 2f_u g_{u_x})^2. \end{aligned} \tag{24}$$

In addition to the invariant equation $f_u = 0$ (equation (9)) that we found in the previous section, here we have also the following three invariant equations:

$$f_u g_{u_xu_x} - 2ff_{uu} = 0, \tag{25}$$

$$\begin{aligned} &-4u_x^2 ff_{uu} - 8u_x ff_{xu} - 4ff_{xx} - 16fg_u + 8u_x fg_{uu_x} + 8fg_{xu_x} + 3u_x^2 f_u^2 \\ &\quad + 6u_x f_x f_u + 20gf_u - 8u_x f_u g_{u_x} + 3f_x^2 - 8f_x g_{u_x} - 8gg_{u_xu_x} + 4g_{u_x}^2 = 0, \end{aligned} \tag{26}$$

$$4u_x ff_{uu} + 4ff_{xu} - 3u_x f_u^2 - 3f_x f_u - 2f_u g_{u_x} = 0. \tag{27}$$

To show this we need to apply the second prolongation (10) of (4) to these equations. That is, we have to show that

$$Y_2^{(2)}(\phi)|_{\phi=0} = 0, \qquad Y_\phi^{(2)}(\phi)|_{\phi=0} = 0, \qquad Y_\psi^{(2)}(\phi)|_{\phi=0} = 0,$$

where ϕ is the left hand side of equations (25), (26) and (27).

We make the following remarks: If equation (1) is such that

1. All four equations (9), (25)–(27) hold, then it has no invariants. We note that if (9) holds, then equations (25) and (27) are satisfied.
2. Equation (9) holds, then it has one invariant, $J_2 = 0$.
3. Equations (26) and (27) hold, then it has one invariant, J_1.
4. Equation (25) holds (but not (9)), then it has two invariants, $J_1 = 0$, J_2.
5. Equation (26) holds, then it has two invariants, J_1, $J_2 = 0$.
6. Equation (27) holds, then it has two invariants, J_1, $J_2' = \frac{1}{J_2} = 0$.

Finally, we make a comment on the invariant equation $f_u = 0$. From this relation we deduce that when two equations of the form (1) are connected by a point transformation, the corresponding functions $f(x,u)$ must both depend on u, or both do not depend on u. From this we can deduce that there exists **no** point transformation that maps an equation of the form (1) with $f_u \neq 0$ to the linear heat equation $u_t = u_{xx}$. In general, an equation of the form (1) with $f_u \neq 0$ cannot be linearised by a point transformation.

Example. We consider the integrable equation

$$u_t = u^2 u_{xx} \tag{28}$$

and the class of equations

$$u_t = u^n u_{xx} + g(x,u,u_x). \tag{29}$$

Both of these equations are special forms of (1). Setting $f = u^2$ and $g = 0$ into equations (23) and (24) we find that equation (28) has invariants $J_1 = -1$ and $J_2 = 1$. From (23) and (24) we deduce that equation (29) has invariants $J_1 = -1$ and $J_2 = 1$ if it is of the form

$$u_t = u^n u_{xx} + \frac{1}{2}(n-2)u^{n-1}u_x^2 + k(x)u^n u_x + \frac{2}{n}\frac{\mathrm{d}k}{\mathrm{d}x}u^{n+1} + h(x)u^{\frac{3n+4}{4}}. \tag{30}$$

Now if we consider transformation (2), it can be shown that the most general form of (30) (and consequently of (29)) that can be linked with (28) is

$$u_t = u^n u_{xx} + \frac{1}{2}(n-2)u^{n-1}u_x^2 + k(x)u^n u_x + \frac{2}{n}\frac{\mathrm{d}k}{\mathrm{d}x}u^{n+1}. \tag{31}$$

In fact, it can be shown that the transformation

$$x \mapsto \int \mathrm{e}^{\int k(x)\mathrm{d}x}\mathrm{d}x, \qquad t \mapsto t, \qquad u \mapsto \mathrm{e}^{\int k(x)\mathrm{d}x}u^{\frac{n}{2}}$$

maps (28) into (31).

5 Remarks

We have shown that the class of equations (1) has no differential invariants of order zero and order one. We have determined two functionally independent differential invariants of second order. In order to produce higher order invariants, we need to follow the procedure as above by considering higher order prolongations, or alternatively we can introduce the idea of invariant differentiation. Details about invariant differentiation can be found in the book of Ibragimov [3].

We note that for the invariants (23) and (24) we need to have $f_u \neq 0$. Hence in the case where $f_u = 0$, that is equation $u_t = f(x)u_{xx} + g(x,u,u_x)$, needs to be considered separately. However, by introducing a new space variable $\xi = \int \frac{1}{f(x)}\mathrm{d}x$, this latter equation takes the form $u_t = u_{\xi\xi} + h(\xi,u,u_\xi)$. The problem of classification of differential invariants for the class of equations $u_t = u_{xx} + g(x,u,u_x)$ will be considered in a separate article in the near future.

Conservation Laws and Potential Systems of Diffusion-Convection Equations

Nataliya M. IVANOVA

Institute of Mathematics of NAS of Ukraine, 3 Tereshchenkivska Str., 01601 Kyiv-4, Ukraine
E-mail: *ivanova@imath.kiev.ua*

We investigate conservation laws of diffusion-convection equations to construct first-order potential systems corresponding to these equations. We do two iterations of the construction procedure, looking, in the second step, for the first-order conservation laws of the potential systems obtained in the first step.

In her famous paper [14] Emmy Noether proved that each Noether symmetry associated with a Lagrangian generates a conservation law. (Modern treatment of relationship between components of Noether conserved vector and Lie–Bäcklund operators which are Noether symmetries was adduced in [10,18]. Kara *et al* [12,13] constructed conservation laws of some classes of PDEs with two independent variables using nonlocal symmetries.) V.A. Dorodnitsyn and S.R. Svirshchevskii [8] (see also [9, Chapter 10]) completely studied the conservation laws for reaction-diffusion equations

$$u_t = (d(u)u_x)_x + q(u).$$

In [1] a detailed discussion of the local nature of conservation laws derived from Noether's theorem is presented.

A *conservation law* of a system of PDEs $\Delta(x, u_{(r)}) = 0$ is a divergence expression $\operatorname{div} F = 0$ which vanishes for all solutions of these system. Here $x = (x_1, \dots, x_n)$, $u = (u^1, \dots, u^m)$. $F = (F^1, \dots, F^n)$, where $F^i = F^i(x, u_{(r)})$, is a conserved vector of this conservation law $u_{(r)}$ is the set of all the partial derivatives of the function u with respect to x of order no greater than r, including u as the derivative of zero order. We call the maximal order of derivatives explicitly appear in f as the *order* of the conservation law $\operatorname{div} F = 0$.

The conservation laws are closely connected with non-local (potential) symmetries. A system of PDEs may admit symmetries of such sort when some of the equations can be written in a conserved form. After introducing potentials for PDEs written in the conserved form as additional dependent variables, we obtain a new (potential) system of PDEs. Any local invariance transformation of the obtained system induces a symmetry of the initial system. If transformations of some of the "non-potential" variables explicitly depend on potentials, this symmetry is a non-local (potential) symmetry of the initial system. More details about potential symmetries and their applications can be found in [4–6].

In this paper we consider conservation laws and potential systems for nonlinear diffusion-convection equations of the form

$$u_t = (d(u)u_x)_x + k(u)u_x, \tag{1}$$

that have a number of applications in physics (see for instance [2, 3, 11]). Here $d = d(u)$ and $k = k(u)$ are arbitrary smooth functions of u, $d(u) \neq 0$.

The complete and strong group classification of (1) was presented in [15] (see also references therein for more details about symmetry analysis of classes intersecting class (1)). The conservation laws associated with first-order potential systems for equations from class (1) with $k = 0$ were considered in [7]. However, some of conservation laws and potential systems were

missing there since the authors did not investigate some necessary differential consequences of considered systems.

Note 1. If a local transformation connects two PDEs then under the action of this transformation a conservation law of the first of these equations is transformed into a conservation law of the second equation, i.e. the equivalence transformation establishes a one-to-one correspondence between conservation laws of these equations. So, we can consider a problem of investigation of conservation laws with respect to the equivalence group of the initial class.

Taking into account Note 1 we start our investigation of potential systems and conservation laws for the class (1) from finding equivalence transformations. Using the classical Lie approach, we find the Lie invariance algebra of equivalence group $G^{\rm equiv}$ for class (1).

Theorem 1 (see [15,16]). *The Lie algebra of the equivalence group $G^{\rm equiv}$ for the class* (1) *is*

$$A^{\rm equiv}=\langle\partial_t,\ \partial_x,\ \partial_u,\ t\partial_t-d\partial_d-k\partial_k,\ x\partial_x+2d\partial_d+k\partial_k,\ u\partial_u,\ t\partial_x-\partial_k\rangle.$$

For class (1) there also exists a nontrivial group of discrete equivalence transformations generated by three involutive transformations of the coupled alternation of signs in the sets of variables $\{t,d,k\}$, $\{x,k\}$ and $\{u\}$. It can be proved by the direct method that $G^{\rm equiv}$ coincides with the group generated by the both continuous and discrete above transformations.

Theorem 2 (see [15,16]). *Any transformation from $G^{\rm equiv}$ has the form*

$$\tilde t=\varepsilon_4 t+\varepsilon_1,\quad \tilde x=\varepsilon_5 x+\varepsilon_7 t+\varepsilon_2,\quad \tilde u=\varepsilon_6 u+\varepsilon_3,\quad \tilde d=\varepsilon_4^{-1}\varepsilon_5^2 d,\quad \tilde k=\varepsilon_4^{-1}\varepsilon_5 k-\varepsilon_7,$$

where $\varepsilon_1,\ \dots,\ \varepsilon_7$ are arbitrary constants, $\varepsilon_4\varepsilon_5\varepsilon_6\neq 0$.

First we search the first-order conservation laws for equations from class (1) in the form

$$D_tF(t,x,u,u_t,u_x)+D_xG(t,x,u,u_t,u_x)=0, \tag{2}$$

where D_t and D_x are the operators of the total differentiation with respect to t and x correspondingly, namely, $D_t=\partial_t+u_t\partial_u+\cdots$, $D_x=\partial_x+u_x\partial_u+\cdots$. Although this is the simplest class of conservation laws, it allows us to deduce first-order potential systems

$$v_x=F,\qquad v_t=-G. \tag{3}$$

Such systems as a rule admit a lot of nontrivial symmetries and so they are of a great interest.

Definition 1. Two conservation laws $D_tF+D_xG=0$ and $D_tF'+D_xG'=0$ are *equivalent* if

$$F'=F+D_xH,\qquad G'=G+D_tH,$$

where H is an arbitrary function of the same variables as the functions F and G.

Theorem 3. *A complete set of inequivalent (with respect to the above equivalence relation) conservation laws of the form* (2) *and potential systems* (3) *for equations from class* (1) *is exhausted by the simple numbered cases of Table 1.*

Proof. Let us substitute expression for u_{xx} deduced from (1) into equation (2) and decompose obtained equation with respect to u_{tt} and u_{tx}. As a result we have

$$F=F^0(t,x,u,u_x),\qquad G=-F^0_{u_x}u_t+G^0(t,x,u,u_x).$$

Table 1. Conservation laws and potential systems.

N	d	k	F	G	Potential system
1	$\forall$	$\forall$	u	$-du_x-\int k$	$v_x=u,\ v_t=du_x+\int k$
1.1	$\forall$	d	e^xv	$-e^x\int d$	$v_x=u,\ w_x=e^xv,\ w_t=e^x\int d$
1.2	$\forall$	$\int d+ud$	e^v	$-e^v\int d$	$v_x=u,\ w_x=e^v,\ w_t=e^v\int d$
1.3	$\forall$	0	v	$-\int d$	$v_x=u,\ w_x=v,\ w_t=\int d$
1.4	u^{-2}	u^{-2}	σe^x	$\sigma_vu^{-1}e^x$	$v_x=u,\ w_x=\sigma e^x,\ w_t=-\sigma_vu^{-1}e^x$
1.5	u^{-2}	0	σ	σ_vu^{-1}	$v_x=u,\ w_x=\sigma,\ w_t=-\sigma_vu^{-1}$
1.6	1	0	αv	$\alpha_xv-\alpha u$	$v_x=u,\ w_x=\alpha v,\ w_t=\alpha u-\alpha_xv$
1.7	1	$2u$	αe^v	$\alpha_xe^v-\alpha ue^v$	$v_x=u,\ w_x=\alpha e^v,\ w_t=\alpha ue^v-\alpha_xe^v$
2	$\forall$	d	$(e^x+\varepsilon)u$	$-(e^x+\varepsilon)du_x-\varepsilon\int d$	$v_x=(e^x+\varepsilon)u,\ v_t=(e^x+\varepsilon)du_x+\varepsilon\int d$
2.1	u^{-2}	u^{-2}	$\dfrac{e^x}{(e^x+\varepsilon)^2}v$	$\dfrac{e^x}{(e^x+\varepsilon)u}$	$v_x=(e^x+\varepsilon)u,\ w_x=\dfrac{e^x}{(e^x+\varepsilon)^2}v,$ $w_t=-\dfrac{e^x}{(e^x+\varepsilon)u}$
3	$\forall$	0	xu	$\int d-xdu_x$	$v_x=xu,\ v_t=xdu_x-\int d$
3.1	$\forall$	0	$x^{-2}v$	$-x^{-1}\int d$	$v_x=xu,\ w_x=x^{-2}v,\ w_t=x^{-1}\int d$
3.2	1	0	$\alpha x^{-1}v$	$(\alpha_xx^{-1}+\alpha x^{-2})v-\alpha u$	$v_x=xu,\ w_x=\alpha x^{-1}v,$ $w_t=\alpha u-(\alpha_xx^{-1}+\alpha x^{-2})v$
4	1	0	αu	$\alpha_xu-\alpha u_x$	$v_x=\alpha u,\ v_t=\alpha u_x-\alpha_xu$
4.1	1	0	$\left(\dfrac{\beta}{\alpha}\right)_x v$	$-\alpha\left(\dfrac{\beta}{\alpha}\right)_x u-\left(\dfrac{\beta}{\alpha}\right)_t v$	$v_x=\alpha u,$ $w_x=\left(\dfrac{\beta}{\alpha}\right)_x v,\quad w_t=\alpha\left(\dfrac{\beta}{\alpha}\right)_x u+\left(\dfrac{\beta}{\alpha}\right)_t v$

Here $\varepsilon\in\{0,\pm1\}$, $\int d=\int d(u)du$, $\int k=\int k(u)du$; $\alpha(t,x)$, $\beta(t,x)$ and $\sigma(t,v)$ are arbitrary solutions of the linear heat equation ($\alpha_t+\alpha_{xx}=0$, $\beta_t+\beta_{xx}=0$, $\sigma_t+\sigma_{vv}=0$).

Taking into account the latter equations and splitting the rest of equation (2) step by step with respect to the powers of u_t and u_x, we obtain a system of PDEs on functions F^0 and G^0. Integrating these equations results in

$$F=D_x\varphi-\psi u,\qquad G=\chi-D_t\varphi+d\psi u_x+\psi\textstyle\int k(u)du-\psi_x\int d(u)du,$$
$$\psi_t+d\psi_{xx}-k\psi_x=0, \tag{4}$$

where $\varphi=\varphi(t,x,u)$, $\chi=\chi(t)$, $\psi=\psi(t,x)$. With respect to the equivalence relation of conservation laws we can assume that $\varphi=\chi=0$. Solving classifying equation (4) for different values of d and k we obtain Cases 1, 2, 3 and 4 of Table 1. ■

Let us consider first-order conservation laws of potential systems 1–4 from Table 1 which have the form

$$D_tF(t,x,u,v,u_t,u_x,v_t,v_x)+D_xG(t,x,u,v,u_t,u_x,v_t,v_x)=0. \tag{5}$$

These laws indeed nonlocal conservation laws for equations from class (1).

Lemma 1. *Any conservation law of form* (5) *for any from systems 1–4 from Table 1 is equivalent to the law with the conserved density F and the flux G that are independent of the derivatives u_t, u_x, v_t and v_x.*

Theorem 4. *A complete set of inequivalent (with respect to the above equivalence relation) conservation laws of the form* (5) *for equations from class* (1) *is presented in Table 1 with a double numeration of cases.*

Note 2. To prove Theorem 4 we use all functionally independent differential consequences of correspondent potential systems. In Table 1 for the double numerated potential systems we omit equations containing v_t since they are only differential consequences of equations of these systems.

Note that potential symmetries arising for equations (1) from Case 1 and 1.4 of Table 1 were found by C. Sophocleous [17]. The complete group classification of potential system corresponding to Case 1 of Table 1 was carried out in [16].

We plan to continue investigations of the subject. For the class under consideration we plan to perform complete classification of potential and nonclassical (conditional) symmetries. We also plan to study conservation laws of the more general structure (the high-order conservation laws and conservation laws with pseudopotentials).

On Realizations of the Conformal Algebra and Nonlinear Invariant Equations in Low-Dimensional Space-Time

Victor LAHNO

Poltava State Pedagogical University, 2 Ostrograds'kogo Str., 36003 Poltava, Ukraine
E-mail: *lvi@pdpu.septor.net.ua, laggo@poltava.bank.gov.ua*

This paper devoted to description of conformally-invariant PDE in low-dimensional spaces.

1 Introduction

This talk is devoted to the question, "What is the most general partial differential equation invariant under a given local Lie group?"

Principal object of our consideration is the second-order partial differential equation

$$F(x, u, \underset{1}{u}, \underset{2}{u}) = 0 \tag{1}$$

invariant under the conformal group $C(1,n)$ and its subgroups – the Poincaré group $P(1,n)$ and extended Poincaré group $\tilde{P}(1,n)$ acting as Lie transformation groups in the space $V = \mathbb{R}(1,n) \times \mathbb{R}^r$ of independent and dependent variables, where $\mathbb{R}(1,n)$ is the pseudo-Euclidean space with the metric tensor

$$g_{\alpha\beta} = \begin{cases} 1, & \alpha = \beta = 0, \\ 0, & \alpha \neq \beta, \\ -1, & \alpha = \beta = 1, 2, \ldots, n. \end{cases} \tag{2}$$

The Lie algorithm requires using for construction of invariant equations not local transformations groups, but the respective Lie algebras of symmetry operators (realizations of Lie algebras in the class of first-order linear differential operators). In our case these linear operators have the form

$$Q = \xi_\mu(x,u)\partial_{x_\mu} + \eta_k(x,u)\partial_{u_k}, \qquad \mu = 0, 1, \ldots, n, \quad k = 1, 2, \ldots, r. \tag{3}$$

A set of $1 + n + C^2_{1+n}$ differential operators P_μ, $J_{\alpha\beta} = -J_{\beta\alpha}$, $\mu, \alpha, \beta = 0, 1, \ldots, n$ of the form (3) satisfying the commutation relations

$$\begin{aligned} &[P_\alpha, P_\beta] = 0, \qquad [P_\alpha, J_{\beta\gamma}] = g_{\alpha\beta}P_\gamma - g_{\alpha\gamma}P_\beta, \\ &[J_{\alpha\beta}, J_{\mu\nu}] = g_{\alpha\nu}J_{\beta\mu} + g_{\beta\mu}J_{\alpha\nu} - g_{\alpha\mu}J_{\beta\nu} - g_{\beta\nu}J_{\alpha\mu} \end{aligned} \tag{4}$$

is called a realization of the Poincaré algebra $p(1,n)$.

A set of $2 + n + C^2_{n+1}$ differential operators $P_\mu, J_{\alpha\beta}, D$ of the form (3) satisfying the commutation relations (4) and

$$[D, J_{\alpha\beta}] = 0, \qquad [P_\alpha, D] = P_\alpha \tag{5}$$

is called a realization the extended Poincaré algebra $\tilde{p}(n,m)$.

A set of $3+2n+C^2_{1+n}$ differential operators P_μ, $J_{\alpha\beta}$, D, K_μ of the form (3) satisfying the commutation relations (4), (5) and

$$[K_\alpha, K_\beta]=0, \qquad [K_\alpha, J_{\beta\gamma}]=g_{\alpha\beta}K_\gamma - g_{\alpha\gamma}K_\beta,$$
$$[P_\alpha, K_\beta]=2(g_{\alpha\beta}D - J_{\alpha\beta}), \qquad [D, K_\alpha]=K_\alpha$$

is called a realization of the conformal algebra $c(1,n)$.

The following realization of the conformal algebra $c(1,n)$ is well-known in many problems of mathematical physics:

$$P_\mu=\partial_{x_\mu}, \qquad J_{\mu\nu}=g_{\mu\gamma}x_\gamma\partial_{x_\nu}-g_{\nu\gamma}x_\gamma\partial_{x_\mu}, \qquad D=x_\mu\partial_{x_\mu}+\epsilon u_k\partial_{u_k}, \quad \epsilon=0,1,$$
$$K_\mu=2g_{\mu\nu}x_\nu D-(g_{\alpha\beta}x_\alpha x_\beta)\partial_{x_\mu}, \qquad \alpha,\beta,\mu,\nu,\gamma=0,1,\dots,n, \quad k=1,\dots,r. \tag{6}$$

In the following we call this realization the standard realization of the conformal algebra.

For the realization (6) in the case of arbitrary n and r the problem of description of equations of the form (1) invariant with respect to the Poincaré group, the extended Poincaré group and the conformal group was completely solved by W.I. Fushchych and I.A. Yehorchenko in [1].

However, the following question will be natural: do other realizations of the algebras $p(1,n)$, $\tilde{p}(1,n)$ and $c(1,n)$ in the class of operators (3) exist that would be different from the standard? In this respect the problem of description of non-equivalent realizations for the algebras $p(1,n)$, $\tilde{p}(1,n)$, $c(1,n)$ in the class of operators (3) will be relevant. W. Fushchych, R. Zhdanov and V. Lahno [2] showed that in the case when translation operators have the form (6)

$$P_\mu=\partial_{x_\mu}, \qquad \mu=0,1,\dots,n,$$

and $V=\mathbb{R}(1,n)\times\mathbb{R}^1$, $n\geq 3$, realizations of the Poincaré algebra $p(1,n)$ and of the extended Poincaré algebra $\tilde{p}(1,n)$ are equivalent to the standard realization (6). The conformal algebra $c(1,n)$, besides the standard realization (6), has also the following one:

$$P_\mu=\partial_{x_\mu}, \qquad J_{\mu\nu}=g_{\mu\gamma}x_\gamma\partial_{x_\nu}-g_{\nu\gamma}x_\gamma\partial_{x_\mu},$$
$$D=x_\mu\partial_{x_\mu}+u\partial_u, \qquad K_\alpha=2g_{\alpha\beta}x_\beta D-\left(g_{\mu\nu}x_\mu x_\nu\pm u^2\right)\partial_{x_\alpha}.$$

Note, this realization is realized on the set of solutions of the eikonal equation

$$g_{\mu\nu}u_{x_\mu}u_{x_\nu}\pm 1=0,$$

and on the set of solutions of d'Alembert–eikonal system

$$g_{\mu\nu}u_{x_\mu}u_{x_\nu}\pm 1=0, \qquad g_{\mu\nu}u_{x_\mu x_\nu}\pm nu^{-1}=0.$$

Realizations for the spaces $V=\mathbb{R}(1,1)\times\mathbb{R}^1$ and $V=\mathbb{R}(1,2)\times\mathbb{R}^1$ were studied in more detail. Below we will consider these results in particular.

2 $\tilde{P}(1,1)$-, $\tilde{P}(1,1)$- and $C(1,1)$-invariant equations

Here $V=\mathbb{R}(1,1)\times\mathbb{R}^1$, $\mathbb{R}(1,1)=\langle t,x\rangle$, $\mathbb{R}^1=\langle u\rangle$, $u=u(t,x)$. G. Rideau and P. Winternitz [3] considered the issue of description of equations

$$F(t,x,u,u_t,u_x,u_{tt},u_{tx},u_{xx})=0, \tag{7}$$

that are invariant with respect to the groups $P(1,1)$, $\tilde{P}(1,1)$ and $C(1,1)$. For this purpose they first described realizations of the Lie algebras of these groups assuming that

$$P_0=\partial_t, \qquad P_1=\partial_x. \tag{8}$$

Their results can be summarized by the following lists:

1. Inequivalent realizations of the Poincaré algebra:

$$p^1(1,1):\{P_0=\partial_t,\ P_1=\partial_x,\ J_{01}=x\partial_x+t\partial_x\};$$
$$p^2(1,1):\{P_0=\partial_t,\ P_1=\partial_x,\ J_{01}=x\partial_t+t\partial_x+u\partial_u\}.$$

2. Inequivalent realizations of the extended Poincaré algebra:

$$\tilde{p}^1(1,1):\left\{p^1(1,1),D=t\partial_t+x\partial_x\right\};$$
$$\tilde{p}^2(1,1):\left\{p^1(1,1),D=t\partial_t+x\partial_x+u\partial_u\right\};$$
$$\tilde{p}^3(1,1):\left\{p^2(1,1),D=\left(t+au+bu^{-1}\right)\partial_t+(x+au-bu^{-1})\partial_x+\lambda u\partial_u\right\},$$

where $\lambda\in\mathbb{R}$, $(a,b)=(0,0)$ or $\lambda=1$, $(a,b)=(1,0)$ or $\lambda=-1$, $(a,b)=(0,1)$.

3. Inequivalent realizations of the conformal algebra:

$$c^1(1,1):\left\{\tilde{p}^1(1,1),\ K_0=\left(t^2+x^2\right)\partial_t+2tx\partial_x,\ K_1=-\left(t^2+x^2\right)\partial_x-2tx\partial_t\right\};$$
$$c^2(1,1):\left\{\tilde{p}^2(1,1),\ K_0=\left(t^2+x^2+au^2\right)\partial_t+2tx\partial_x+2tu\partial_u,\right.$$
$$\left.K_1=-\left(t^2+x^2+au^2\right)\partial_x-2tx\partial_t-2xu\partial_u,\ a=0,1,-1\right\};$$
$$c^3(1,1):\left\{\tilde{p}^3(1,1)\ (\lambda\in\mathbb{R},\ a=b=0),\ K_0=\left(t^2+x^2+cu^2+du^{-2}\right)\partial_t\right.$$
$$\left.+\left(2tx+cu^2-du^{-2}\right)\partial_x+\left(2u(x+\lambda t)+eu^2+k\right)\partial_u,\ K_1=-[J_{01},K_0]\right\},$$

where if $\lambda\in\mathbb{R}$, $\lambda\neq\pm1$, then $c=d=e=k=0$; if $\lambda=1$, then $d=k=0$, $c=\pm1$, $e\in\mathbb{R}$ or $c=0$, $e=0,\pm1$; if $\lambda=-1$, then $c=e=0$, $d=\pm1$, $k\in\mathbb{R}$ or $d=0$, $k=0,1$.

The realizations $p^2(1,1)$, $\tilde{p}^3(1,1)$, $c^2(1,1)$ $(a\neq0)$ and $c^3(1,1)$ are non-equivalent to the standard realizations (6).

Use of non-standard realizations allowed G. Rideau and P. Winternitz to add to the list of equations obtained by W. Fushchych and I. Yehorchenko, new invariant equations. We [4] give up the condition (8) and set the problem of description of all inequivalent realizations of the algebras $p(1,1)$, $\tilde{p}(1,1)$, $c(1,1)$. As a result, we obtained one new realization of the algebra $p(1,1)$

$$p^3(1,1):\left\{P_0=\partial_t,\ P_1=x\partial_t,\ J_{01}=xt\partial_t+\left(x^2-1\right)\partial_x\right\}$$

and two new realizations of the algebra $\tilde{p}(1,1)$:

$$p^4(1,1):\left\{p^3(1,1),\ D=t\partial_t\right\};$$
$$\tilde{p}^5(1,1):\left\{p^3(1,1),\ D=t\partial_t+u\partial_u\right\}.$$

The $p^3(1,1)$-invariant equation of the form (7) will have following form:

$$\Phi(\mathcal{J}_1,\ldots,\mathcal{J}_5)=0, \tag{9}$$

where

$$\mathcal{J}_1=u,\qquad \mathcal{J}_2=u_t^2\left(x^2-1\right),\qquad \mathcal{J}_3=u_{tt}\left(x^2-1\right),$$
$$\mathcal{J}_4=\left(x^2-1\right)^2\left(u_xu_{tt}-u_tu_{tx}\right)-x\left(x^2-1\right)u_t^2,$$
$$\mathcal{J}_5=\left(x^2-1\right)\left(u_{tt}u_{xx}-u_{tx}^2\right)+2x\left(x^2-1\right)^2\left(u_xu_{tt}-u_tu_{tx}\right)-x^2\left(x^2-1\right)u_t^2.$$

$\tilde{p}^4(1,1)$- and $\tilde{p}^5(1,1)$-invariant equations have the form

$$\bar{\Phi}(\Sigma_1,\Sigma_2,\Sigma_3,\Sigma_4)=0, \tag{10}$$

where

$$\Sigma_1 = \mathcal{J}_1, \qquad \Sigma_2 = \mathcal{J}_2^{-1}\mathcal{J}_3, \qquad \Sigma_3 = \mathcal{J}_2^{-2}\mathcal{J}_4, \qquad \Sigma_4 = \mathcal{J}_2^{-2}\mathcal{J}_5, \quad \text{for} \quad \tilde{p}^4(1,1),$$

and

$$\Sigma_1 = \mathcal{J}_1\mathcal{J}_3, \qquad \Sigma_2 = \mathcal{J}_2, \qquad \Sigma_3 = \mathcal{J}_4, \qquad \Sigma_4 = \mathcal{J}_5, \quad \text{for} \quad \tilde{p}^5(1,1).$$

Notice that (9) and (10) include equations which are generations of the well-known Monge–Amperé equations.

Summing up the above, we see that for second-order scalar differential equations in the two-dimensional space-time we may consider the problem of construction of the general equation invariant with respect to the groups $P(1,1)$, $\tilde{P}(1,1)$, $C(1,1)$ to be resolved completely.

3 $P(1,2)$-, $\tilde{P}(1,2)$- and $C(1,2)$-invariant equations

Let us consider in more detail the results obtained for the equation

$$F(x_\mu, u, u_{x_\mu}, u_{x_\mu x_\nu}) = 0, \qquad \mu,\nu = 0,1,2. \tag{11}$$

As we said above, W. Fushchych and I. Yegorchenko gave full description of equations of the form (11), that are invariant with respect to the groups $P(1,2)$, $\tilde{P}(1,2)$ and $C(1,2)$, generated by the standard realizations of the algebras $p(1,2)$, $\tilde{p}(1,2)$, $c(1,2)$:

$$\begin{aligned}
&P_\mu = \partial_{x_\mu}, \qquad J_{\mu\nu} = g_{\mu\gamma}\partial_{x_\nu} - g_{\mu\gamma}x_\gamma\partial_{x_\mu},\\
&D = x_\mu\partial_{x_\mu} + \epsilon u\partial_u, \quad \epsilon = 0,1, \qquad K_\mu = 2g_{\mu\nu}x_\nu D - (g_{\alpha\beta}x_\alpha x_\beta)\partial_{x_\mu},\\
&g_{\mu\nu} = \begin{cases} 1, & \mu=\nu=0,\\ 0, & \mu\neq\nu, \\ -1, & \mu=\nu=1,2, \end{cases} \qquad \alpha,\beta,\gamma,\mu,\nu = 0,1,2.
\end{aligned} \tag{12}$$

I. Yehorchenko [5] found a new realization of the Poincaré group $p(1,2)$:

$$\begin{aligned}
&P_\mu = P_{x_\mu}, \qquad J_{01} = x_0\partial_{x_1} + x_1\partial_{x_0} + \sin u\partial_u,\\
&J_{02} = x_0\partial_{x_2} + x_2\partial_{x_0} + \cos u\partial_u, \qquad J_{12} = x_2\partial_{x_1} - x_1\partial_{x_2} + \partial_u.
\end{aligned} \tag{13}$$

Later W. Fushchych, R. Zhdanov and V. Lahno [2] showed that in the case $P_\mu = \partial_{x_\mu}$ ($\mu = 0,1,2$) non-equivalent realizations of the algebra $p(1,2)$ are exhausted by realizations (12) and (13) and found new realizations of the algebras $\tilde{p}(1,2)$ and $c(1,2)$ as extensions of the realizations (13) of the algebra $p(1,2)$:

$$\begin{aligned}
&P_\mu, J_{\mu\nu} \ \text{ have the form (13)}, \qquad D = x_\mu\partial_{x_\mu},\\
&K_0 = 2x_0D - (g_{\mu\nu}x_\mu x_\nu)\partial_{x_0} - 2(x_2\cos u + x_1\sin u)\partial_u,\\
&K_1 = -2x_1D - (g_{\mu\nu}x_\mu x_\nu)\partial_{x_1} - 2(x_0\sin u - x_2)\partial_u,\\
&K_2 = -2x_2D - (g_{\mu\nu}x_\mu x_\nu)\partial_{x_2} - 2(x_0\cos u + x_1)\partial_u.
\end{aligned}$$

These results were later re-discovered in a somehow new form by F. Güngor [6].

I. Yehorchenko [7] also obtained a general form of the equation (11), that is invariant with respect to the realization (13) of the algebra $p(1,2)$.

We aim to obtain the complete description of inequivalent realizations of the algebras $p(1,2)$, $\tilde{p}(1,2)$, $c(1,2)$, that might be invariance algebras for equation of the form (11). The list of results of our calculations [8] is given below. There are four new cases.

New realizations of the algebra $p(1,2)$

Case 1. Let the operators P_μ have the form

$$P_0 = \partial_{x_0}, \qquad P_1 = \partial_{x_1}, \qquad P_2 = x_2\partial_{x_0} + u\partial_{x_1}.$$

Then there is only one class of inequivalent realizations of the algebra $p(1,2)$, whose operators $J_{\mu\nu}$ can be taken as follows:

$$J_{01} = x_1\partial_{x_0} + x_0\partial_{x_1} + u\partial_{x_2} + x_2\partial_u, \qquad J_{02} = x_0x_2\partial_{x_0} + ux_0\partial_{x_1} + \left(x_2^2 - 1\right)\partial_{x_2} + ux_2\partial_u,$$
$$J_{12} = -x_1x_2\partial_{x_0} - x_1u\partial_{x_1} - x_2u\partial_{x_2} - \left(1 + u^2\right)\partial_u.$$

Case 2. Let the operators P_μ have the form

$$P_0 = \partial_{x_0}, \qquad P_1 = \partial_{x_1}, \qquad P_2 = x_2\partial_{x_0} + \varphi\partial_{x_1}, \quad \varphi = \sqrt{x_2^2 - 1}, \quad |x_2| > 1.$$

Then there are four classes of inequivalent realizations of the algebra $p(1,2)$. Their operators $J_{\mu\nu}$ can be taken in the following form:

$$J_{01} = x_1\partial_{x_0} + x_0\partial_{x_1} + \varphi\partial_{x_2}, \qquad J_{02} = (x_0x_2 + a)\partial_{x_0} + (x_0\varphi + b)\partial_{x_1} + \varphi^2\partial_{x_2} + q\partial_u,$$
$$J_{12} = (-x_1x_2 + \alpha)\partial_{x_0} + (-x_1\varphi + \beta)\partial_{x_1} - x_2\varphi\partial_{x_2} + p\partial_u.$$

Here a, b, α, β, q, p take the following values:

1. $a = \beta = \lambda = \text{const},\ \alpha = b = -\epsilon e^{-2u},\ \epsilon = 0, 1,\ q = -x_2,\ p = \varphi;$
2. $a = \beta = \lambda_1\left[\dfrac{u}{1-u^2} + \dfrac{1}{2}\ln\left|\dfrac{1+u}{1-u}\right|\right] + \lambda_2,$
   $\alpha = b = \lambda_1[1-u^2]^{-1},\ q = \varphi - x_2u,\ p = \varphi u - x_2,\ \lambda_1, \lambda_2 = \text{const};$
3. $a = -\beta = \lambda x_2\varphi,\ b = \lambda x_2^2,\ \alpha = -\lambda\varphi^2,\ q = p = 0,\ \lambda = \text{const};$
4. $a = -\beta = x_2\varphi u,\ b = x_2^2u,\ \alpha = -\varphi^2u,\ q = p = 0.$

Case 3. Let the operators P_μ have the form

$$P_0 = \partial_{x_0}, \qquad P_1 = x_1\partial_{x_0}, \qquad P_2 = \psi\partial_{x_0}, \qquad \psi = \pm\sqrt{1 - x_1^2}, \quad |x_1| < 1.$$

Then there are three classes of inequivalent realizations of the algebra $p(1,2)$. Their operators $J_{\mu\nu}$ can be taken in the following form:

$$J_{01} = (x_0x_1 + B\psi)\partial_{x_0} - \psi^2\partial_{x_1} + (Cx_1 + D\psi)\partial_{x_2} + A\psi\partial_u,$$
$$J_{02} = (x_0\psi - x_1B)\partial_{x_0} + x_1\psi\partial_{x_1} + (C\psi - x_1D)\partial_{x_2} - Ax_1\partial_u,$$
$$J_{12} = \psi\partial_{x_1}.$$

The variables A, B, C, D take the following values:

1. $A = B = C = D = 0;$
2. $A = \sqrt{|x_2|}g(u),\ B = x_2,\ C = 2x_2,\ D = x_2\sqrt{|x_2|}f(u);$
3. $A = x_2f(u),\ B = 0,\ C = x_2,\ D = x_2^2g(u).$

Here f and g are some sufficiently smooth real–valued functions.

Case 4. Finally, let the operators P_μ have the form

$$P_0 = \partial_{x_0}, \qquad P_1 = x_1\partial_{x_0}, \qquad P_2 = x_2\partial_{x_0}.$$

Then there are two classes of inequivalent realizations of the algebra $p(1,2)$. Their operators $J_{\mu\nu}$ can be taken in the following form:

$$J_{12}=x_2\partial_{x_1}-x_1\partial_{x_2},\qquad J_{01}=(x_0x_1+x_2\theta)\partial_{x_0}+\left(x_1^2-1\right)\partial_{x_1}+x_1x_2\partial_{x_2}+x_2\rho\partial_u,$$
$$J_{02}=(x_0x_2-x_1\theta)\partial_{x_0}+x_1x_2\partial_{x_1}+\left(x_2^2-1\right)\partial_{x_2}-x_1\rho\partial_u.$$

The variables θ, ρ take the following values:

1. $\theta=f(u)\left(1-\omega^{-1}\right),\ \omega=x_1^2+x_2^2,\ \rho=0;$
2. $\theta=0,\ \rho=\omega^{-1}\sqrt{|\omega-1|},\ \omega=x_1^2+x_2^2.$

Here f is some sufficiently smooth real-valued function.

Notice that the obtained realizations can be extended to the realizations of the algebra $\tilde{p}(1,2)$ and cannot be extended to the realizations of the algebra $c(1,2)$.

Further application of the obtained realizations for construction of invariant equations results in considerable technical difficulties. For the realization

$$P_0=\partial_{x_0},\qquad P_1=x_1\partial_{x_0},\qquad P_2=x_2\partial_{x_0},\qquad J_{12}=x_2\partial_{x_1}-x_1\partial_{x_2},$$
$$J_{01}=x_0x_1\partial_{x_0}+\left(x_1^2-1\right)\partial_{x_1}+x_1x_2\partial_{x_2},\qquad J_{02}=x_0x_2\partial_{x_0}+x_1x_2\partial_{x_1}+\left(x_2^2-1\right)\partial_{x_2}$$

the search for functions $\mathcal{J}_1$, $\mathcal{J}_2$, …, $\mathcal{J}_7$ in the respective invariant equation

$$F(\mathcal{J}_1,\dots,\mathcal{J}_7)=0$$

showed that they have an extremely cumbersome form. Below we adduce four of the seven functions:

$$\mathcal{J}_1=u,\qquad \mathcal{J}_2=u_{x_0}^2u_{x_0x_0},\qquad \mathcal{J}_3=(\Sigma_1-1)u_{x_0}^2,$$
$$\mathcal{J}_4=\Sigma_1^{-1}\left[(1-\Sigma_1)^3(2\Sigma_1\Sigma_2u_{x_0}^2+(1-\Sigma_1)\Sigma_2^2+\Sigma_3^2)+u_{x_0}^4(\Sigma_1-1)^2\Sigma_1^2\right],$$

where

$$\Sigma_1=x_1^2+x_2^2,\qquad \Sigma_2=x_1(u_{x_1}u_{x_0x_0}-u_{x_0}u_{x_0x_1})+x_2(u_{x_2}u_{x_0x_0}-u_{x_0}u_{x_0x_2}),$$
$$\Sigma_3=x_2(u_{x_1}u_{x_0x_0}-u_{x_0}u_{x_0x_1})-x_1(u_{x_2}u_{x_0x_0}-u_{x_0}u_{x_0x_2}).$$

We believe that in this respect a constructive problem may be presented by a problem of description of conformally invariant equations of the considered form using the basis of differential invariants for the standard realization found by W. Fushchych and I. Yehorchenko realization and realization (12) of the algebra $p(1,2)$.

We examine the integrability, in terms of the Painlevé singularity analysis and of the Lie symmetry analysis, of systems of nonlinear first-order ordinary differential equations that arise in the particular area of Mathematical Modelling known as Rational Epidemiology. These analyses are presented as being complementary to the standard analysis using the methods of Dynamical Systems. The importance to obtain complete understanding of evolution of epidemics – one need think only of the potential for devastation by HIV-AIDS in African countries or the more recent threat posed by SARS – demands that all possible approaches of analysis be used. The concept of decomposed systems is introduced as illustrating some rather attractive mathematical properties of certain classes of systems of equations arising in Mathematical Modelling. Such systems allow the mathematician some opportunity to enjoy Mathematics even in the context of quite strict applications.

1 Introduction

There are four standard approaches to the analysis of a system of nonlinear first-order ordinary differential equations of the type which arise frequently in Mathematical Modelling. The approaches comprise numerical computation, dynamical systems, singularity analysis and symmetry analysis, all of which possess extensive literatures.

This work is concerned with Mathematical Modelling with particular emphasis on Rational Epidemiology. In particular our specialisation is to systems of first-order ordinary differential equations, i.e. compartmental models, in contrast to systems of partial differential equations. Thus we stress the evolutionary aspect of an epidemic in contrast to the dispersion in space, which happens when one uses partial differential equations. Obviously we can consider only a subset, and a simple one at that, of the class of models which can be investigated, but one can argue a case for the commencement with the simple. Here we concentrate upon the singularity and symmetry aspects of models. There are already many who have devoted much effort and ingenuity to the application of the methods of Dynamical Systems to and/or the determination of numerical solutions of these models.

A particular subset, the recently christened 'decomposed' systems, attracts our attention for the mathematical relief provided in the midst of the human – equally animal or vegetable should the system to be so modelled – misery underlying our studies.

There are some general and particular reasons for our interest. To general reasons are the need for sophisticated Mathematical Modelling in an environment of finite resources and rampant consumerism and the need to determine whether we live in the midst of potentially chaotic

systems. In the particular case of Rational Epidemiology there is a need to develop the mathematical models and their analyses to the fullest extent of our ability. In this modern era we have the burden of crowding and widespread intermingling of diverse population groups with the consequent dangers of the catastrophic spreading of deadly diseases. Even in the slower times the catastrophe of a pandemic could make its mark for many centuries. In the context of the African Continent the spectre of depopulation consequent upon HIV-AIDS is a reality. This provides a case study for mathematical modelling which in the magnitude of its implications is probably a worthy successor of the Black Death that devastated Europe 700 years ago.

The structure of this paper is as follows. In Sections 2, 3 and 4 we examine certain specific epidemiological models in terms of the symmetry and/or singularity analyses. In Section 5 we introduce the notion of 'decomposition' and indicate some of the properties of a particular example of a decomposed system. We conclude with some remarks and observations in Section 6.

2 A model for the transmission of HIV-AIDS

The model [24],

$$\dot{u}_1 = -\frac{\beta c u_1 u_2}{u_1+u_2+u_3} - \mu u_1, \qquad \dot{u}_2 = \frac{\beta c u_1 u_2}{u_1+u_2+u_3} - (\mu+\nu)\, u_2, \qquad \dot{u}_3 = \nu u_2 - \alpha u_3, \quad (1)$$

has been quite successful in replicating results reported in studies of HIV transmission in the San Francisco area [12, 27]. The variables $u_i(t)$, $i = 1, 3$ represent that part of population which is HIV negative, is HIV positive and has AIDS respectively. The parameter μ is the death rate from normal causes, α the death rate from AIDS and ν the rate at which HIV positives develop AIDS. The parameters β and c represent the rates of infection and change of partner respectively.

By inspection one notes that the system (1) possesses the two Lie point symmetries

$$\Gamma_1 = \partial_t \qquad \text{and} \qquad \Gamma_2 = u_1\partial_{u_1} + u_2\partial_{u_2} + u_3\partial_{u_3}$$

with the Abelian algebra $2A_1$.

The presence of the symmetry Γ_2, representing homogeneity in the dependent variables, precludes the possibility that the system (1) possess the Painlevé Property.

These two symmetries are insufficient for integrability in the sense of Lie. A third symmetry, which would constitute a three-dimensional solvable Lie algebra with these two, is required.

As a system of first-order equations (1) has an infinite number of Lie point symmetries. Infinity is not a satisfactory number. We use the second part of the method of reduction of order [18–20] to replace the system of three first-order equations by a system of one second-order equation and one first-order equation.

In the analysis of this system, obtained by the elimination of u_3 from (1a), one finds that the system is separable and linearisable in the case that $\alpha = \mu + \beta c$. The symmetry

$$\Gamma_3 = \exp\left[-(\mu+\nu)t\right]\partial_{u_2} + \frac{u_1+u_3}{u_2}\exp\left[-(\mu+\nu)t\right]\partial_{u_3}$$

provides the third element of the required solvable algebra.

The explicit solution to the system (1) is found to be

$$u_1 = \frac{e^{\nu t}c_2}{e^{\mu t}\left[e^{\nu t}\left(\beta\, c-\nu\right)c_1 + e^{\beta\, c\, t}\beta\, c\,\right]},$$

$$u_2 = \frac{\left(\beta\, c-\nu\right)\int \frac{e^{\beta\, c\, t+2\nu t}}{\left(e^{\beta\, c\, t}\beta\, c + e^{\nu t}\beta\, c\, c_1 - e^{\nu t}c_1\nu\right)^2}\,\mathrm{d}\, t}{\beta\, c\, c_2 + c_3} e^{\mu t+\nu t},$$

$$u_3 = \frac{\left[e^{\nu t}\left(\beta\, c-\nu\right)c_1 + e^{\beta\, c\, t}\nu\right]c_3}{e^{\beta\, c\, t+\mu t+\nu t}\left(\beta\, c-\nu\right)} + \frac{e^{\nu t}\, c_2}{e^{\mu t}\left[e^{\nu t}\left(\beta\, c-\nu\right)c_1 + e^{\beta\, c\, t}\beta\, c\,\right]}$$
$$+ \frac{\beta\, c\, c_2\left[e^{\nu t}\left(\beta\, c-\nu\right)c_1 + e^{\beta\, c\, t}\nu\right]\int e^{\beta\, c\, t+2\nu t}\left(e^{\beta\, c\, t}\beta\, c\, + e^{\nu t}\beta\, c\, c_1 - e^{\nu t}c_1\nu\right)^2 \mathrm{d}\, t}{\exp[\beta\, c\, t + \mu t + \nu t]}$$

for general values of the parameters subject to the constraint $\alpha = \mu + \beta c$.

There is a considerable simplification if in addition $\beta c = 2\nu$. The failure of the system to possess the Painlevé Property is quite manifest in this case for the solution is given in closed-form as

$$\begin{aligned}
u_1 &= \frac{c_1}{e^{\mu t}\left(2e^{\nu t} + c_1 c_2\right)},\\
u_2 &= \left[2e^{\nu t}\log\left(2e^{\nu t} + c_1 c_2\right)c_1 - 2e^{\nu t}c_1 + 4e^{\nu t}c_3\right.\\
&\quad \left. + \log\left(2e^{\nu t} + c_1 c_2\right)c_1^2 c_2 + 2c_1 c_2 c_3\right] / \left[2e^{\mu t+\nu t}\left(2e^{\nu t} + c_1 c_2\right)\right],\\
u_3 &= \left[e^{\nu t}\log\left(2e^{\nu t} + c_1 c_2\right)c_1 - 2e^{\nu t}c_1 + 2e^{\nu t}c_3\right.\\
&\quad \left. + \log\left(2e^{\nu t} + c_1 c_2\right)c_1^2 c_2 + 2c_1 c_2 c_3\right] / \left[2e^{\mu t+2\nu t}\right].
\end{aligned}$$

One notes with interest that the constraint, $\alpha = \mu + \beta c$, which leads to the integrability of the system (1) in the sense of Lie, fits quite well with observational data accumulated over the last twenty years in the United States.

This coincidence of a relationship between the parameters of a system leading to better properties in terms of integrability and the practical realisation of that relationship in terms of the modelling of reality is intriguing and is sufficient to prompt one to pursue the possibility of a similar coincidence in other models.

3 The classic $S - I - R$ model

The model introduced by Kermack and McKendrick [13] to describe the effects of the Black Death in the seventeenth century is

$$\dot{S} = -rSI, \qquad \dot{I} = rSI - aI, \qquad \dot{R} = aI, \tag{2}$$

where S is the proportion of the population susceptible to the infection, I the proportion of population infected by the infection and R that proportion of population removed from consideration either through recovery with immunity or death. The parameters r and a represent the rate of infection and the rate of removal respectively.

When we add the three equations comprising (2), we have

$$(S + I + R)^{\cdot} = 0,$$

i.e. $\dot{N} = 0$, where $N = S + I + R$.

Obviously $\dot{N} = 0 \implies N = \text{const} = 1$.

The parameter-free form of the system (2) is

$$\dot{x} = -xy, \qquad \dot{y} = xy - y, \qquad \dot{z} = y, \tag{3}$$

where

$$S = \frac{a}{r}x, \qquad I = \frac{a}{r}y, \qquad R = \frac{a}{r}z, \qquad t = \frac{t}{r},$$

with the obvious summation $(x + y + z)^{\cdot} = 0$.

The Painlevé analysis of the system (3) fails immediately since the exponents of the leading order terms are not all negative. An attempt to rescue the Painlevé analysis by the dropping of the third member of (3) is encouraging since the exponent of the leading order term of the remaining two variables is -1 and the resonances are at ± 1. Unfortunately the system fails the test for consistency. Consequently a logarithmic term must be introduced and this destroys the integrability in the sense of Painlevé.

In the system (3) the variable z is ignorable and the system is a candidate for the application of the technique of reduction of order. The quotients (3a)/(3c) and (3b)/(3c) are

$$\frac{\mathrm{d}x}{\mathrm{d}z} = -x \qquad \text{and} \qquad \frac{\mathrm{d}y}{\mathrm{d}z} = x - 1. \tag{4}$$

We ignore the trivial route to the solution of the system (4) and persist with the spirit of the method of reduction of order to reduce the pair of first-order equations to a single second-order equation through the elimination of the dependent variable x. We obtain

$$\frac{\mathrm{d}^2y}{\mathrm{d}z^2} + \frac{\mathrm{d}y}{\mathrm{d}z} = 1, \tag{5}$$

which is a linear second-order ordinary differential equation in $y(z)$, indeed, it is a quasi-first-order equation in the first derivative of the function.

The integration of (5) and hence (4) is trivial. However, in the case of (3c) we have

$$\dot{z} = A + z - B\mathrm{e}^{-z},$$

where A and B are the constants of integration introduced at the solution of (5), the quadrature of which in closed-form is not possible.

We note that in the reduction of the system (3) to (5) we have reduced the nonlinear system to a linear system and also that (5), as a linear second-order ordinary differential equation, possesses eight Lie point symmetries.

4 Some curious facets of gonorrhoea

A somewhat simplified model [16] for the sexually transmitted disease gonorrhoea is described by the system

$$\dot{S} = -sSI^* + aI, \qquad \dot{I} = rSI^* - aI, \qquad \dot{S}^* = -r^*S^*I + a^*I^*, \qquad \dot{I}^* = r^*S^*I - a^*I^*, \tag{6}$$

in which the lower case letters are the rate constants and the symbols for susceptibles and infectives are obvious. The population is divided into two groups, male and female, and each of these two groups is divided into susceptibles and infectives. The females are distinguished by the possession of an asterisk. The model assumes free mixing which is generally not a valid assumption for sexually transmitted diseases. However, as one is informed, the properties of gonorrhoea are such to permit this assumption. The simplification in the model is that, since gonorrhoea does not confer immunity and so a person who has been treated returns to the classes of susceptibles, the time of treatment, during which one hopes the interaction between infectives and susceptibles is suspended, is regarded as negligible. The populations of males and females are assumed to be constant.

There are three conservation laws, *videlicet*

$$\dot{N} = 0, \qquad \dot{N}^* = 0 \qquad \text{and} \qquad \dot{P} = 0, \tag{7}$$

where $N = S + I$, $N^* = S^* + I^*$ and $P = N + N^*$.

The leading order behaviour is given by

$$S = -\frac{1}{r^*}\tau^{-1}, \qquad I = \frac{1}{r^*}\tau^{-1}, \qquad S^* = -\frac{1}{r}\tau^{-1}, \qquad I^* = \frac{1}{r}\tau^{-1} \tag{8}$$

and the resonances occur at -1 and 1(3).

The consistency of the system is determined by the substitution of

$$S = a_i\tau^{i-1}, \qquad I = b_i\tau^{i-1}, \qquad S^* = c_i\tau^{i-1}, \qquad I^* = d_i\tau^{i-1}$$

into the full system (6) with the leading order terms as given in (8). Fortunately the location of the resonance at $+1$ makes the calculation fairly easy. At the positive resonance we obtain the system

$$\begin{bmatrix} 1 & 0 & 0 & -\frac{r}{r^*} \\ -1 & 0 & 0 & \frac{r}{r^*} \\ 0 & -\frac{r^*}{r} & 1 & 0 \\ 0 & \frac{r^*}{r} & -1 & 0 \end{bmatrix} \begin{bmatrix} a_1 \\ b_1 \\ c_1 \\ d_1 \end{bmatrix} = \begin{bmatrix} -\frac{a}{r^*} \\ \frac{a}{r^*} \\ -\frac{a^*}{r} \\ \frac{a^*}{r} \end{bmatrix}.$$

Performance of the row operations $R_2' = R_2 + R_1$ and $R_4' = R_4 + R_3$ leads to the simpler system

$$\begin{bmatrix} 1 & 0 & 0 & -\frac{r}{r^*} \\ 0 & 0 & 0 & 0 \\ 0 & -\frac{r^*}{r} & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} a_1 \\ b_1 \\ c_1 \\ d_1 \end{bmatrix} = \begin{bmatrix} -\frac{a}{r^*} \\ 0 \\ -\frac{a^*}{r} \\ 0 \end{bmatrix}$$

in which the consistency is self-evident.

We have the explicit relations

$$a_1 = \frac{1}{r^*}\left(a + rd_1\right) \qquad \text{and} \qquad c_1 = \frac{1}{r}\left(a^* + r^*b_1\right). \tag{9}$$

There are two arbitrary constants introduced at the resonance, i.e. the geometric multiplicity of the eigenvector is two. However, the algebraic multiplicity of the eigenvalue is three.

The Laurent expansion contains only three arbitrary constants – the two introduced in (9) and the location of the movable pole – so that it does not represent the general solution of the system (6).

To obtain the general solution one must introduce a logarithmic term at the resonance and this destroys the analytic nature of the solution.

We continue our analysis of the system (6) by transforming the system of first-order equations to a scalar higher-order equation. From (7) we obtain

$$I = N - S \qquad \text{and} \qquad I^* = N^* - S^*. \tag{10}$$

With (10) equations (6b) and (6d) may be written as

$$-\dot{S} = rS(N^* - S^*) - a(N - S), \tag{11}$$

$$-\dot{S}^* = r^* S^* (N - S) - a^* (N^* - S^*). \tag{12}$$

We substitute for S^* from (11) into (12) to obtain a single second-order equation for S, *videlicet*

$$\begin{aligned} &S\ddot{S} - \dot{S}^2 - r^* S^2 \dot{S} + \left(r^* N + a^*\right) S\dot{S} + aN\dot{S} - r^* \left(N^* r + a\right) S^3 \\ &\quad + \left(NN^* r r^* + 2Nar^* + aa^*\right) S^2 - aN \left(r^* N + a^*\right) S = 0. \end{aligned} \tag{13}$$

The first three terms in (13) are dominant. The exponent of the leading order term is -1 and the resonances are at ± 1. To establish that there is consistency when the coefficient of the resonant term firstly enters we examine the coefficients in (summation on repeated indices is implied)

$$\begin{aligned} &(i-1)(i-2)a_i a_j \tau^{i+j-4} - (i-1)(j-1)a_i a_j \tau^{i+j-4} - (i-1) r^* a_i a_j a_k \tau^{i+j+k-4} \\ &\quad + \left(r^* N + a^*\right)(i-1) a_i a_j \tau^{i+j-3} + aN(i-1) a_i \tau^{i-2} - r^* \left(rN^* + a\right) a_i a_j a_k \tau^{i+j+k-3} \\ &\quad + \left(NN^* r r^* + 2aNr^* + aa^*\right) a_i a_j \tau^{i+j-2} - aA \left(r^* N + a^*\right) a_i \tau^{i-1} = 0. \end{aligned}$$

The coefficient of τ^{-4} gives

$$2a_0^2 - a_2^2 + r^* a_0^3 = 0 \implies a_0 = -\frac{1}{r^*} \tag{14}$$

and the coefficient of τ^{-3} gives

$$2a_0 a_1 + r^* a_0 (2a_2 a_1) - (r^* N + a^*) a_0^2 - r^* (rN^* + a) a_0^3 = 0. \tag{15}$$

When the value of a_0 from (14) is substituted into (15), the coefficient of a_1 is identically zero as one expects. The terms remaining impose the condition

$$r^* N + a = rN^* + a^*. \tag{16}$$

Subject to the constraint (16) on the parameters in (13) the latter equation has an analytic solution for $S(t)$. It follows from (11) that $S^*(t)$ is also analytic and from (10) that $I(t)$ and $I^*(t)$ are also analytic.

This analysis simply reinforces the conclusion reached above that the three-parameter solution obtained for the original system, (6), is analytic away from the movable polelike singularity.

This type of integrability, which occurs for specific values of the first integrals of the base system determined by the relationship (16), is something of a generalisation of the integrability which occurs when an integral takes a particular value, i.e. in the context of a configurational invariant [8, 23].

The solution obtained is not the general solution of (6) since it lacks the requisite four arbitrary constants of integration. However, we have demonstrated the existence of an analytic solution of (6) containing three arbitrary constants of integration. Such solutions are not unknown [11, p. 355].

In the past this type of solution has been interpreted as indicating that the system is at least integrable on a surface in the space of initial conditions [5, 22]. This interpretation has not been universally accepted [4]. Since the inference of an analytic solution has been the basis for the interpretation in the past, there has been room for disagreement over the interpretation. However, in this instance the interpretation is based upon explicit demonstration of the analytic nature of the solutions for each of the component functions of the system.

One instance does not prove a universal fact. On the other hand one instance does disprove the denial of the possibility.

The system (6) and the scalar equation (13) have the obvious Lie symmetry, ∂_t, which reflects their autonomy. Even with the constraint (16) there appears to be no other point symmetries. This is a little curious as one would expect some additional symmetry to match the better quality of the system in terms of integrability. Perhaps this is to be found as either a generalised or a nonlocal symmetry.

5 Decomposed systems

There are several standard models for the rate of change of a population which is of sufficient magnitude to be treated as a continuum. They are

$$\textbf{1}.\quad \frac{\mathrm{d}N}{\mathrm{d}t} = 0 \quad \Leftrightarrow \quad N(t) = N_0. \tag{17}$$

This is the trivial model and applies if one is considering a population over a period of time sufficiently small for the normal means of increase and decrease of population not to have any effect. The famous SIR model of Kermack and McKendrick [13], *videlicet*

$$\dot{S} = -rSI, \qquad \dot{I} = rSI - aI, \qquad \dot{R} = aI, \tag{18}$$

is an example for, if we sum the three equations, we obtain

$$(S + I + R)^{\cdot} = 0$$

which is just (17). One recalls that the system (18) was used to model the Great Plague of 1666-7 in London and did it very well.

$$\textbf{2}.\quad \frac{\mathrm{d}N}{\mathrm{d}t} = K \quad \Leftrightarrow \quad N(t) = N_0 + Kt. \tag{19}$$

The constant rate of increase of the population described by (19) enables one to do a little more than with (17) without a serious increase in mathematical difficulty. An integrable model of this genre is the $S - I - R$ system

$$\dot{S} = -\beta SI - \mu S + \gamma I + \mu K, \qquad \dot{I} = \beta SI - (\mu + \gamma)I, \qquad \dot{R} = \mu(S + I). \tag{20}$$

The sum of the three equations in the system (20) gives

$$(S + I + R)^{\cdot} = \mu K$$

which is precisely the form of (19).

$$\textbf{3}.\quad \frac{\mathrm{d}N}{\mathrm{d}t} = \sigma N \quad \Leftrightarrow \quad N(t) = N_0 \exp[\sigma t]. \tag{21}$$

This is the famous model publicised by the Englishman, Thomas Malthus, in 1798 [17]. An integrable model of this genre is the $S - I - S$ system [21]

$$\dot{S} = -\beta SI - \mu S + \gamma I + \mu K, \tag{22}$$

$$\dot{I} = \beta SI - (\mu + \gamma)I, \tag{23}$$

i.e. (20) when the third equation of the system is ignored in the analysis. We sum these two equations to obtain

$$(S + I)^{\cdot} = \mu K - \mu(S + I)$$

which is precisely of the type (21) if we set $S + I - K = N$.

$$\textbf{4}.\quad \frac{\mathrm{d}N}{\mathrm{d}t} = \sigma N \left(1 - \frac{N}{C}\right) \quad \Leftrightarrow \quad N(t) = \frac{CN_0}{N_0 + (C - N_0)\exp[-\sigma t]} \tag{24}$$

in which the additional parameter C is of the nature of a 'carrying capacity'. This variation was introduced in 1838 [25] by Verhulst to obviate the excesses to which the model of Malthus led.

These four models may be regarded as successive approximations of the same phenomenon. For a short period of time one could treat the population as a constant. For a longer period of time a constant rate of increase is not unreasonable. The next model is to assume that the rate is proportional to the existing population and finally one must take into account the limitations of the environment in which the population is growing by adding the additional term due to Verhulst.

Because these different models have validity for different regimes it is possible to find a mixture of growth rates in a population containing varied components. An early example of this is found in an extension to the model proposed by Volterra [26,3] of a predator-prey system of two types of fish in the Adriatic. The model of Volterra is

$$\dot{N} = aN - bPN, \qquad \dot{P} = -cP + dPN. \tag{25}$$

A similar model, connected to chemical reactions, was proposed by Lotka [15] about the same time.

The bilinear term PN is typical of Lotka–Volterra models. In this model the prey N is taken to have Malthusian growth with the implicit assumption that the predator P consumes sufficient of the prey for the Malthusian growth not to test the limits of the carrying capacity of the local environment. If this be not the case, the Malthusian term should be replaced by a logistic term – for some reason generally Verhulst is forgotten in the naming – so that (25a) is replaced by

$$\dot{N} = aN\left(1 - \frac{N}{C}\right) - bPN.$$

Since the Malthusian term in (25b) gives a reduction in the population of the predator, there is no need to introduce a logistic term here.

The four model equations, *videlicet* (17), (19), (21) and (24), are trivially integrable and possess the Painlevé Property.

The systems (18), (20) and (22)–(23) have the property that their sums are simply (17), (19) and (21) respectively.

The same behaviour is not found with the Lotka–Volterra model (25) except for unexpectedly agreeable values of the parameters.

Systems such as the $S - I - R$ model represented by (18) which can be summed to give a single scalar equation in one variable are called 'decomposed systems' [2] and may be viewed as decomposition of the single equation, (17) in the case of (18), according to some rule.

Under which rules of decomposition are the decomposed systems integrable?

The general decomposition cannot be expected to be integrable. We consider an example [6, 7, 14] which has its origin in the operator Yang–Baxter equations of Mathematical Physics, but we do so in reverse. The two-dimensional system

$$\dot{r} = 2rw, \qquad \dot{w} = r^2 + w^2 \tag{26}$$

can be considered to be the decomposition of the Riccati equation

$$\dot{z} = z^2, \tag{27}$$

where $z = r + w$. A further decomposition is

$$\dot{p} = 2pw + \lambda qw, \qquad \dot{q} = 2qw - \lambda wp, \qquad \dot{w} = (p+q)^2 + w^2, \tag{28}$$

where $r = p + q$.

As a Riccati equation (27) possesses the Painlevé Property and is integrable in terms of analytic functions. The first decomposed system (26) is equally integrable. The second decomposed system (28) is integrable in the sense that the dependent variables can be written as explicit expressions of the independent variable, but the system does not possess the Painlevé Property since its solution is not in terms of analytic functions.

A whole class of problems has been excluded from even the possibility of consideration here. We are concerned with populations with a rate of change which is either independent of the population or proportional in some sense to the total population. In some populations, microbes come to mind, this is not unreasonable as microbes become capable of replication rather quickly. On the other hand populations comprising more complicated species can be divided into the three classes of nonreproductive due to immaturity, reproductive and nonreproductive due to – shall we politely put it – postmaturity.

This class of population lies outside the class of decomposible systems considered here.

Even models for which the reproductive aspect is not of major relevance can still exhibit various ways to be decomposed from a simpler system. A model for HIV infection in a homosexual population,

$$\begin{aligned} \dot{X} &= B - \mu X - \lambda c X, \qquad \dot{Y} = \lambda c X - (\nu + \mu) Y, \\ \dot{A} &= p\nu Y - (d + \mu) A, \qquad \dot{Z} = (1 - p)\nu Y - \mu Z, \end{aligned} \tag{29}$$

sums to give the rate of change of the total population as

$$\dot{N} = B - \mu N - dA,$$

where B represents the recruitment rate of susceptibles into the population, μ is the natural rate of demise and d the additional rate of demise of the AIDS-afflicted portion of the population A.

In the absence of AIDS the system (29) fits into the scheme of decomposition. In the absence of AIDS perhaps the population being modelled would not attract so much interest.

Our present interest in decomposible systems is motivated by the existence of decomposed systems as models of actual phenomena, in particular epidemiology.

Decomposed systems entered the literature from a more mathematical direction. In 2002 Imai and Hirata [9] published their investigations of the existence of autonomous symmetries of the form

$$\Gamma = \phi_i(x) \partial_{x_i}$$

for the autonomous system

$$\dot{\boldsymbol{x}} = \boldsymbol{g}(x),$$

where $\mathbf{g}(x)$ and the coefficient functions $\phi_i(x)$ are analytic in the neighbourhood of some fixed point. Their interest was in the determination of integrable systems through an algebraic approach. As applications they considered n-dimensional homogeneous, that is to say quadratic, Lotka–Volterra systems of the form

$$\dot{x} = x_i \sum_{j=1}^{n} a_{ij} x_j, \qquad i = 1, n. \tag{30}$$

Imai and Hirata considered some very specific examples of (30) which they termed the ladder system and the generalised ladder system [10].

The n-dimensional ladder system is the system (30) with the specific coefficient matrix

$$A = (a_{ij}) = \begin{bmatrix} 1 & 0 & \cdots & -n+2 \\ 2 & 1 & \cdots & -n+3 \\ \vdots & \vdots & & \vdots \\ n & n-1 & \cdots & 1 \end{bmatrix},$$

i.e. the elements of the matrix A are given by

$$a_{ij} = a_i + 1 - a_j \qquad \text{and} \qquad a_{i+1,j} - a_{ij} = 1.$$

The ladder system has certain general properties [1].

Proposition 1.

$$\det A = \begin{cases} 1, & n = 1, 2, \\ 0, & n > 2. \end{cases}$$

Corollary. *The rank of the matrix A is two for $n > 2$.*

Proposition 2. *The n-dimensional ladder system can be considered as the simplest Riccati equation for $\sum_{i=1}^{n} x_i$.*

Proposition 3. *The ratio of two successive solutions of the ladder system is*

$$\frac{x_{i+1}}{x_i} = \frac{K_i}{t - t_0}.$$

Proposition 4. *The solution of the n-dimensional ladder system is given by*

$$x_{i+1} = x_1 \frac{\prod_{j=1}^{i} K_j}{(t - t_0)^i}, \tag{31}$$

where

$$x_1 = -\frac{(t - t_0)^{n-2}}{\sum_{j=0}^{n-1} \left(\prod_{k=0}^{j} K_k \right) (t - t_0)^{n-1-j}}. \tag{32}$$

We consider the group classification problem for the class of control systems which is described by systems of ordinary differential equations, and we give the full group classification for the second-order control systems.

1 Introduction

Recently there has been quite a few publications dealing with the symmetries of control systems. Nevertheless, most of them deal with particular symmetry problems for concrete control systems. Others in some, perhaps hidden, form attempt to solve the problem of finding symmetries for the "general case". It means that the problem is formulated for control systems of the form

$$\dot{x}^i = f^i(t,x,u), \qquad i=\overline{1,n}, \quad t\in\mathbb{T}\subset\mathbb{R}_+, \quad u\in\mathbb{U}^*\subset\mathbb{R}^r, \quad x\in\mathbb{X}^*\subset\mathbb{R}^n \tag{1}$$

for arbitrary $\{f^i(\cdot), n, r\}$. Symmetry conditions for the coefficients τ, ξ^i, φ^j of the infinitesimal generator of the form

$$X=\tau(t,x,u)\frac{\partial}{\partial t}+\xi^i(t,x,u)\frac{\partial}{\partial x^i}+\varphi^j(t,x,u)\frac{\partial}{\partial u^j} \tag{2}$$

read as

$$Xf^i-X_0\xi^i+f^iX_0\tau=0, \qquad U_j\xi^i+f^iU_j\tau=0, \qquad i=\overline{1,n}, \quad j=\overline{1,r}, \tag{3}$$

where

$$X_0=\frac{\partial}{\partial t}+f^i\frac{\partial}{\partial x^i}, \qquad U_j=\frac{\partial}{\partial u^j}. \tag{4}$$

Up to now there is no recipe for solving system (3) with arbitrary functions $f^i(\cdot)$ and arbitrary numbers (n,r). So, we need to fix something. Following L. Ovsiannikov's approach, we will describe our systems by fixing (n,r) for arbitrary $f^i(\cdot)$ and, hence, we will consider a classical group classification problem for some class of control systems. In the present paper we consider the case $n=2$, but before that we give some remarks on a definition of equivalence of control systems.

2 Feedback equivalence and essential controls of control systems

Definition 1. System (1) and any system which can be derived from (1) via a diffeomorphism $\hat{t}=\hat{t}(t,x), \hat{x}=\hat{x}(t,x), \hat{u}=\hat{u}(t,x,u)$ are called feedback equivalent control systems.

Based on this definition we can define also the notion of so called "essential controls", a natural generalization of the notion of "essential parameters" (see, for example, [2]).

Definition 2. Controls u^j are called essential ones if there are no controls v^k $(k < r)$, for which $f^i(t,x,u) = \hat{f}^i(t,x,v)$.

Using Definitions 1 and 2 we can give the following proposition.

Proposition 1. *Any control system with r essential controls is feedback equivalent to the system of the (canonical) form*

$$\begin{aligned}
&\dot{x}^1 = f^1(t,x,u),\\
&\dot{x}^2 = f^2(t,x,u),\\
&\cdots\cdots\cdots\cdots\\
&\dot{x}^{n-r} = f^{n-r}(t,x,u),\\
&\dot{x}^{n-r+1} = u^1,\\
&\dot{x}^{n-r+2} = u^2,\\
&\cdots\cdots\cdots\cdots\\
&\dot{x}^n = u^r.
\end{aligned} \tag{5}$$

It follows from Proposition 1 that there is only one canonical one-dimensional $(n = 1)$ control system $\dot{x} = u$, so the group classification of this system is trivial. Thus, we start from the case $n = 2$.

3 Canonical forms for second-order control systems

Obviously (see Proposition 1), there exist only two canonical forms for second-order control systems. One of them (with 2 controls) reads

$$\begin{aligned}
&\dot{x}^1 = u^1,\\
&\dot{x}^2 = u^2,
\end{aligned} \tag{6}$$

and the second one (with a single control) looks like

$$\begin{aligned}
&\dot{x}^1 = F\left(t, x^1, x^2, u\right),\\
&\dot{x}^2 = u.
\end{aligned} \tag{7}$$

Of course, we ignore the case $u^j = 0$. System (6) does not contain any arbitrary elements and its symmetry generator is given by the direct sum $Y = Y_1 \oplus Y_2 \oplus Y_3$ with

$$\begin{aligned}
&Y_1 = \tau\partial_t - Y_0\tau\left(u^1\partial_{u^1} + u^2\partial_{u^2}\right),\\
&Y_2 = \xi^1\partial_{x^1} + \left(Y_0\xi^1\right)\partial_{u^1}, \qquad Y_3 = \xi^2\partial_{x^2} + \left(Y_0\xi^2\right)\partial_{u^2},
\end{aligned} \tag{8}$$

with $\tau = \tau(t,x)$, $\xi^i = \xi^i(t,x)$ arbitrary functions and $Y_0 = \partial_t + u^1\partial_{u^1} + u^2\partial_{u^2}$.

4 Controllability

Controllability (strong accessibility) is known to be directly related to the existence of invariants (first integrals). As we can see below, controllability plays an important role in the group properties of control systems.

Definition 3. We call system (7) (locally) uncontrollable, if (locally) all its solutions (trajectories) lie in an invariant manifold of the form $\omega\left(t, x^1, x^2\right) = C$.

Thus, the existence of such a manifold means that there exists a function ω depending on (t, x^1, x^2) such that $\dot{\omega} = 0$ (i.e., ω is invariant under the action of the input u).

We will now discuss for which choice of $F\left(t, x^1, x^2, u\right)$ in (7) there exist such invariants. To this end we interpret the invariant $\omega\left(t, x^1, x^2\right) = C$ as a nontrivial solution of the system of partial differential equations

$$\frac{\partial \omega}{\partial t} + F\left(t, x^1, x^2, u\right)\frac{\partial \omega}{\partial x^1} + u\frac{\partial \omega}{\partial x^2} = 0, \qquad \frac{\partial \omega}{\partial u} = 0, \tag{9}$$

where the first equation means that ω must be a first integral of system (7), and the second condition means that this first integral must be independent of u. If we denote

$$X_0 = \frac{\partial}{\partial t} + F\left(t, x^1, x^2, u\right)\frac{\partial}{\partial x^1} + u\frac{\partial}{\partial x^2}, \qquad U = \frac{\partial}{\partial u}, \tag{10}$$

system (9) takes the form

$$X_0\omega = 0, \qquad U\omega = 0. \tag{11}$$

In order to look for the functionally independent solutions of system (11), we need to calculate the involutive closure [3] for a distribution of vector fields given as (10). We get the Lie brackets

$$\begin{aligned} &X_1 = [U, X_0] = F_u\frac{\partial}{\partial x^1} + \frac{\partial}{\partial x^2}, \qquad X_2 = [U, X_1] = F_{uu}\frac{\partial}{\partial x^1}, \\ &X_3 = [X_0, X_1] = \left(F_{ut} + FF_{ux^1} + uF_{ux^2} - F_uF_{x^1} - F_{x^2}\right)\frac{\partial}{\partial x^1}. \end{aligned} \tag{12}$$

System (7) admits a first integral if for the above vector fields the two conditions $U \wedge X_0 \wedge X_1 \wedge X_2 = 0$ and $U \wedge X_0 \wedge X_1 \wedge X_3 = 0$ are fulfilled simultaneously. The first condition reads

$$\begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & F & u \\ 0 & 0 & F_u & 1 \\ 0 & 0 & F_{uu} & 0 \end{vmatrix} = F_{uu} = 0, \tag{13}$$

the second is

$$\begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & F & u \\ 0 & 0 & F_u & 1 \\ 0 & 0 & F_{ut} + FF_{ux^1} + uF_{ux^2} - F_uF_{x^1} - F_{x^2} & 0 \end{vmatrix} = 0. \tag{14}$$

Therefore, system (7) is uncontrollable if and only if the function F satisfies the following two conditions:

$$F_{uu} = 0, \qquad F_{ut} + FF_{ux^1} + uF_{ux^2} - F_uF_{x^1} - F_{x^2} = 0. \tag{15}$$

One direct implication of these results is the following.

Corollary 1. *System* (7) *is uncontrollable if and only if* $F = \alpha\left(t, x^1, x^2\right)u + \beta\left(t, x^1, x^2\right)$ *and the coefficients* α *and* β *satisfy*

$$\alpha\beta_{x^1} - \beta\alpha_{x^1} - \alpha_t + \beta_{x^2} = 0.$$

Example 1. The linear system

$$\dot{x}^1 = a_1 x^1 + a_2 x^2 + bu,$$
$$\dot{x}^2 = u$$

will be uncontrollable if and only if the condition $ba_1 + a_2 = 0$ holds true. Indeed, elimination of u leads us to the Pfaffian equation

$$dx^1 - bdx^2 + a_1 \left(bx^2 - x^1\right) dt = 0,$$

which has solutions of the form

$$\omega(t, x^1, x^2) = \left(bx^2 - x^1\right) e^{-a_1 t} = C.$$

5 Group classification for system (7)

As we analyze a whole class of systems of the form (7), with arbitrary function F, there naturally occurs a problem of group classification [4]: For the class of systems (7) find the kernel of basic groups GE_0 and all specializations of the arbitrary function F which allow us to extend the basic groups.

Notice that in accordance with the terminology of the book [4], the kernel of basic groups is the symmetry group admitted by system (7) for all specializations of the function F. Therefore, in our case the kernel of basic groups is empty (i.e., $GE_0 = \{0\}$), because the function F depends on all variables.

Hence, we start our analysis deriving the so-called *determining equations*. In order to determine the coefficients $\tau\left(t, x^1, x^2, u\right)$, $\xi^i\left(t, x^1, x^2, u\right)$, $\varphi\left(t, x^1, x^2, u\right)$ of the infinitesimal symmetry operator

$$X = \tau \frac{\partial}{\partial t} + \xi^1 \frac{\partial}{\partial x^1} + \xi^2 \frac{\partial}{\partial x^2} + \varphi \frac{\partial}{\partial u} \tag{16}$$

one needs to solve the system

$$Xf^i - X_0 \xi^i + f^i X_0 \tau = 0, \qquad U\xi^i + f^i U\tau = 0, \qquad i = 1, 2, \tag{17}$$

where $f^1 = F$, $f^2 = u$ (see also [5]). Substituting

$$\xi^i = f^i \tau + \hat{\xi}^i \tag{18}$$

in (17) we get

$$\hat{X} f^i - X_0 \hat{\xi}^i = 0 \qquad U\hat{\xi}^i + U(f^i)\tau = 0, \qquad i = 1, 2, \tag{19}$$

where

$$\hat{X} = \hat{\xi}^1 \frac{\partial}{\partial x^1} + \hat{\xi}^2 \frac{\partial}{\partial x^2} + \varphi \frac{\partial}{\partial u}.$$

If in (19) we replace f^2 by u we obtain

$$\varphi = X_0 \hat{\xi}^2, \qquad \tau = -U\hat{\xi}^2. \tag{20}$$

Now substituting (τ, φ) in (17) and replacing f^1 by F we get

$$\hat{\xi}^1 F_{x^1} + \hat{\xi}^2 F_{x^2} + F_u X_0 \hat{\xi}^2 - X_0 \hat{\xi}^1 = 0, \qquad U\hat{\xi}^1 - F_u U\hat{\xi}^2 = 0. \tag{21}$$

If we introduce

$$\sigma = \hat{\xi}^1 - F_u \hat{\xi}^2, \tag{22}$$

from the second equation of (21) we get

$$F_{uu}\hat{\xi}^2 + \sigma_u = 0. \tag{23}$$

Assuming $F_{uu} \neq 0$, solve (22) and (23) for $(\hat{\xi}^1, \hat{\xi}^2)$:

$$\hat{\xi}^1 = \sigma - F_u F_{uu}^{-1}\sigma_u, \qquad \hat{\xi}^2 = -F_{uu}^{-1}\sigma_u. \tag{24}$$

Substituting (24) in the first equation of the system (21), we finally obtain

$$F_{uu}(\sigma_t + F\sigma_{x^1} + u\sigma_{x^2}) + (F_u F_{x^1} + F_{x^2} - F_{tu} - FF_{ux^1} - uF_{ux^2})\sigma_u = F_{uu}F_{x^1}\sigma. \tag{25}$$

Using some substitutions, we reduced our problem to the single equation (25) for the function σ. In accordance with the terminology of [6], this function is called the generating function of symmetries. Indeed, if we are able to solve equation (25) for a particular specialization of the function F then all coefficients can be calculated via

$$\begin{aligned}
&\tau = U\left(F_{uu}^{-1}\sigma_u\right),\\
&\xi^1 = \sigma + FU\left(F_{uu}^{-1}\sigma_u\right) - F_u F_{uu}^{-1}\sigma_u,\\
&\xi^2 = uU\left(F_{uu}^{-1}\sigma_u\right) - F_{uu}^{-1}\sigma_u,\\
&\varphi = -X_0\left(F_{uu}^{-1}\sigma_u\right),
\end{aligned}$$

where $U = \partial_u$. Equation (25) is a quasi-linear inhomogeneous partial differential equation. The corresponding system of characteristics for this equation reads as

$$\begin{aligned}
&\dot{x}^1 = F(t, x^1, x^2, u),\\
&\dot{x}^2 = u,\\
&\dot{u} = F_{uu}^{-1}(F_u F_{x^1} + F_{x^2} - F_{tu} - FF_{ux^1} - uF_{ux^2}),\\
&\dot{\sigma} = F_{x^1}\sigma.
\end{aligned} \tag{26}$$

Thus, the problem of calculation of the point symmetries for (open loop) second-order control systems is reduced to the problem of integration of (closed loop) system (26). Conversely, if we know some symmetries (coefficients τ, ξ^1, ξ^2), we are able to give some first integral of system (26). Indeed, converting formulas (18), (22), (24), we have

$$\sigma = \xi^1 - F_u\xi^2 + (uF_u - F)\tau. \tag{27}$$

Remark 1. With system (7) is associated the Pfaffian system $I = \{\omega^1, \omega^2\}$, where

$$\omega^1 = dx^1 - Fdt, \qquad \omega^2 = dx^2 - udt \tag{28}$$

on a subset of $\mathbb{R}^4$. With I is associated the so-called derived flag [1]. The first derived system $I^{(1)}$ includes the single one-form ω:

$$I^{(1)} = \{\omega = dx^1 + (uF_u - F)dt - F_u dx^2\}. \tag{29}$$

With this we are in a position to define the formula (27) in the intrinsic form

$$\sigma = X \rfloor \omega. \tag{30}$$

where ω is the generator of the first derived flag $I^{(1)}$, $\rfloor$ the inner product, and X the symmetry generator (16).

The conditions (15) for uncontrollability play the role of the classification conditions for equation (25), and if they are met the symmetry algebra is wider (see also [5] for further details).

Let us consider some examples.

Example 2. The linear time-varying system

$$\dot{x}^1 = tu + x^2,$$
$$\dot{x}^2 = u$$

is uncontrollable. Condition (15) is fulfilled and the system has a first integral

$$x^1 - tx^2 = C.$$

The symmetry algebra for this system is spanned by the vector fields

$$X_1 = \gamma(x^1 - tx^2)\partial_{x^1},$$
$$X_2 = -\sigma_u\partial_t + \left(t\sigma - \left(tu + x^2\right)\sigma_u\right)\partial_{x^1} + (\sigma - u\sigma_u)\partial_{x^2} + \left(\sigma_{tu} + \left(tu + x^2\right)\sigma_{ux^1} + u\sigma_{ux^2}\right)\partial_u,$$

where $\gamma\left(x^1 - tx^2\right)$ and $\sigma\left(t, x^1, x^2, u\right)$ are arbitrary functions of the given arguments.

Example 3. For the system in Brunovský normal form

$$\dot{x}^1 = x^2,$$
$$\dot{x}^2 = u$$

one has $F_{uu} = 0$. Thus, in accordance with (25), $\sigma_u = 0$ and $\sigma = \sigma\left(t, x^1, x^2\right)$. The infinitesimal symmetry operator takes the form

$$X = -\sigma_{x^2}\partial_t + \left(\sigma - x^2\sigma_{x^2}\right)\partial_{x^1} + \left(\sigma_t + x^2\sigma_{x^1}\right)\partial_{x^2} + X_0^2(\sigma)\partial_u,$$

where $X_0 = \partial_t + x^2\partial_{x^1} + u\partial_{x^2}$, $\sigma = \sigma\left(t, x^1, x^2\right)$.

Example 4. For the nonlinear system

$$\dot{x}^1 = u^2,$$
$$\dot{x}^2 = u$$

the equation $F_uF_{x^1} + F_{x^2} - F_{tu} - FF_{ux^1} - uF_{ux^2} = 0$ is fulfilled, so (from (25)) it follows that $X_0\sigma = 0$, and $\sigma = \sigma\left(u, x^1 - tu^2, x^2 - tu\right)$. The symmetry operator is

$$X = \sigma_{uu}\partial_t + \left(u^2\sigma_{uu} - 2u\sigma_u + \sigma\right)\partial_{x^1} + (u\sigma_{uu} - \sigma_u)\partial_{x^2} - \left(\sigma_{tu} + u^2\sigma_{x^1u} + u\sigma_{x^2u}\right)\partial_u.$$

On Integrable Systems of ODEs

Maxim W. LUTFULLIN

Poltava State Pedagogical University, 2 Ostrogradsky Str., 36003 Poltava, Ukraine
E-mail: *MWL@pdpu.septor.net.ua*

We classify normal systems of three and four first-order ordinary differential equations (ODEs) that are invariant with respect to three- and four-dimensional solvable real Lie algebras respectively, and therefore can be integrated by the Lie method.

Description of the most general form of systems of differential equations of some type that are invariant with respect to the algebras of a fixed dimension is one of the main problems of group analysis. The standard Lie algorithm leads to classification of such systems if all the realizations of these algebras in Lie vector fields are known [5]. For instance, in [1] the second-order partial differential equations that are invariant under the standard realizations of the Euclid, Poincaré, Galilei, conformal and projective algebras were obtained. New realizations of the above algebras was constructed and a partial differential equations invariant with respect to these realizations were described in [2, 3, 7] (see also references therein).

A necessary step for searching realizations of Lie algebras is classification of these algebras, i.e. classification of possible commutative relations between basic elements. As for solvable Lie algebras, classification was completely made for only low-dimensional algebras. All possible non-isomorphic complex Lie algebras of dimension $N \leq 4$ were listed by S. Lie himself. G.M. Mubarakzyanov was the first who got the complete and suitable for application classification of the real Lie algebras of dimension $N \leq 4$ [4]. In paper [6] that are based on his classification realizations of these algebras in the spaces of the arbitrary finite number of the variables have been classified.

In this paper we construct the systems of the ODEs that are invariant with respect to three- and four-dimensional solvable real Lie algebras using results of [6]. The numeration of algebras and realizations corresponds to that paper: $R(A, N)$ denotes the Nth realization of the algebra A (see Tables 2–4) in [6].

Consider systems of ODEs of the form

$$F_k(t, x, \dot{x}) = 0, \tag{1}$$

where F_k are smooth functions, $k = 1, 2, 3$ for three-dimensional Lie algebras and $k = 1, \ldots, 4$ for four-dimensional ones. We will imply that the variable t is independent, and $x = (x_1, x_2, \ldots, x_k)$ variables are dependent. We denote derivatives with dots over the symbols $\dot{x}_i = \frac{dx_i}{dt}$, $\dot{x} = (\dot{x}_1, \dot{x}_2, \ldots, \dot{x}_k)$.

Let us note that invariant systems obtained by various choices of the independent variable in basis elements of realizations are equivalent to each other. The variables are chosen to simplify calculations in a such way that the canonic forms of realizations would not contain the operator of differentiation with respect to the independent variable. A simplest general form of invariant systems corresponds to this choice. An arbitrary realization of an m-dimensional Lie algebra ($m \leq 4$) is equivalent to a realization into which no more than $m + 1$ first variables explicitly enter. (There is exception is only for the realizations of algebra $4A_1$ with rank 2 and 3, namely $R(4A_1, 2)$, $R(4A_1, 5)$). Under the choice of the respective coordinates and the independent variable ($t = x_{m+1}$), all the variables x_i and $\dot{x}_i$, $i \in \{m+2, \ldots, n\}$ will be invariants. Therefore, we search the differential invariants of realizations of three- and four-dimensional solvable Lie algebras in the space with three (four) dependent variables.

At first we construct the systems of three ODEs that are invariant with respect to realizations of three-dimensional solvable Lie algebras (see Table 2 [6]). Let $x_4 = t$ be an independent variable and x_1, x_2, x_3 be functions of t.

We find the functional bases of the first-order differential invariants for every realization of three-dimensional solvable Lie algebras. The corresponding calculations are not given here as there are quite cumbersome. Using the constructed sets of differential invariants of Lie algebras we obtain the exhaustive list of inequivalent (with respect to arbitrary regular changes of variables) systems of first-order ODEs that are invariant under three-dimensional solvable real Lie algebras.

By the direct verification we make sure that such systems may be reduced to the normal forms if the rank of the corresponding realization equals three.

Theorem 1. *Let system of the three ordinary first-order ODEs be invariant with respect to a realization of a real three-dimensional solvable Lie algebra with rank* 3*. Then the system is integrable in quadratures by means of the Lie method and using the same transformation of variables, which reduce the realization to one of the realizations given in Table* 2 *of* [6]*, we can transform the system to one of the following normal forms:*

$R(3A_1, 1)$ $\quad \dot{x}_1 = f_1(t), \quad \dot{x}_2 = f_2(t), \quad \dot{x}_3 = f_3(t);$

$R(A_{2.1} \oplus A_1, 1)$ $\quad \dot{x}_1 = f_1(t)e^{x_3}, \quad \dot{x}_2 = f_2(t), \quad \dot{x}_3 = f_3(t);$

$R(A_{3.1}, 1)$ $\quad \dot{x}_1 = f_1(t) + x_3\, f_2(t), \quad \dot{x}_2 = f_2(t), \quad \dot{x}_3 = f_3(t);$

$R(A_{3.2}, 1)$ $\quad \dot{x}_1 = [f_1(t) + x_3 f_2(t)]e^{x_3}, \ \dot{x}_2 = f_2(t)e^{x_3}, \ \dot{x}_3 = f_3(t);$

$R(A_{3.3}, 1)$ $\quad \dot{x}_1 = f_1(t)e^{x_3}, \quad \dot{x}_2 = f_2(t)e^{x_3}, \quad \dot{x}_3 = f_3(t);$

$R(A_{3.4}, 1)$ $\quad \dot{x}_1 = f_1(t)e^{x_3}, \quad \dot{x}_2 = f_2(t)e^{ax_3}, \quad \dot{x}_3 = f_3(t);$

$R(A_{3.5}, 1)$ $\quad \dot{x}_1 = f_1(t)e^{bx_3}\sin(x_3 + f_2(t)), \ \dot{x}_2 = f_1(t)e^{bx_3}\cos(x_3 + f_2(t)), \ \dot{x}_3 = f_3(t).$

Further we carry out the similar construction of differential invariants of realizations of four-dimensional solvable real Lie algebras, assuming $x_5 = t$ is the independent variable and x_1, x_2, x_3, x_4 are functions of t. We choose only the realizations that exist in the space of variables x_1, x_2, x_3, x_4, $x_5 = t$.

As to systems of four ODEs which are invariant with respect to the four-dimensional solvable real Lie algebras, in a similar way we obtain the following theorem.

Theorem 2. *Let system of the four ordinary first-order ODEs be invariant with respect to a realization of a real four-dimensional solvable Lie algebra with rank* 4*. Then the system is integrable in quadratures with Lie's method and using the same transformation of variables which reduce the realization to one of the realizations given in Tables* 3 *and* 4 *of* [6] *we can transform the system to one of the following normal forms:*

Recursion Operators for Vacuum Einstein Equations with Symmetries

Michal MARVAN

Mathematical Institute, Silesian University in Opava, Na Rybníčku 1, Czech Republic
E-mail: *Michal.Marvan@math.slu.cz*

Direct and inverse recursion operator is derived for the vacuum Einstein equations for metrics with two commuting Killing vectors that are orthogonal to a foliation by 2-dimensional leaves.

1 Introduction

In the past decade, inverse recursion operators became the subject of a number of papers [7, 8, 14, 15]. In particular, the work of Guthrie [7] opened a new perspective on recursion operators by essentially identifying them with auto-Bäcklund transformations for linearized equation [18].

It is known for a long time that recursion operators of integrable systems are obtainable from their Lax pairs (see [6] and references therein) and ZCR's (see [10, 24]). However, recently it became clear that zero curvature representations are related much closer to inverse recursion operators than to their 'direct' counterparts [19, 20]. Examples that have been already published elsewhere include the Korteweg–de Vries and Tzitzéica equation [19] and the stationary Nizhnik–Novikov–Veselov equation [20]. In the present paper, the methods of [19, 20] are applied to equations of General Relativity.

2 Recursion operators

Let $\mathcal{E} = \{F^l = 0\}$ be a system of PDE's in unknown functions u^k of two independent variables x, y. We assume that F^l are functions of x, y, u^k and a finite number of the derivatives

$$u^k_{ij} = \frac{\partial^{i+j} u^k}{\partial x^i \partial y^j} \qquad \bigl(u^k_{00} = u^k\bigr).$$

Consider the infinite-dimensional jet space J^∞ with local coordinates x, y, u^k_{ij} along with the commuting vector fields

$$D_x = \frac{\partial}{\partial x} + \sum_{ij} u^k_{i+1,j} \frac{\partial}{\partial u^k_{ij}}, \qquad D_y = \frac{\partial}{\partial y} + \sum_{ij} u^k_{i,j+1} \frac{\partial}{\partial u^k_{ij}},$$

called *total derivatives*. The submanifold E determined by equations $F^l = 0$ and their differential consequences $D_x F^l = 0$, $D_y F^l = 0$, $D_x^2 F^l = 0$, $D_x D_y F^l = 0$, $D_y^2 F^l = 0$, …, is called the *equation manifold* (and is an underlying space of the diffiety structure [12] employed in [19]). In this context, infinitesimal symmetries (more precisely, their generating functions) are functions U^k defined on E such that

$$\sum_{k,i,j} \frac{\partial F^l}{\partial u^k_{ij}} D_x^i D_y^j U^k = 0.$$

It is then natural to consider the jet space with coordinates x, y, u^k_{ij}, U^k_{ij}, and denote

$$LF^l = \sum_{k,i,j} \frac{\partial F^l}{\partial u^k_{ij}} U^k_{ij}. \tag{1}$$

The system $L\mathcal{E} := \{F^l = 0,\ LF^l = 0\}$ on unknowns u^k, U^k will be called the *linearized equation*. Now, Guthrie's recursion operators [7] may be interpreted as auto-Bäcklund transformations of the linearized equation $L\mathcal{E}$ that keep variables u^k unchanged [19].

In now standard formalism [21], recursion operators are pseudodifferential operators, characterized by the occurrence of inverses of total derivatives D_x^{-1}. Under Guthrie's approach, $p = D_x^{-1} f$ is introduced as an auxiliary nonlocal variable satisfying

$$p_x = f, \qquad p_y = g, \tag{2}$$

provided such a g exists, and it actually does without known exception; see Sergyeyev [23] for a proof in the case of evolution systems. Thus, p is a potential of a conservation law $f\,dx + g\,dy$ of the linearized equation $L\mathcal{E}$.

For the inverse recursion operators, the nonlocalities tend to be genuinely non-Abelian pseudopotentials related to a zero curvature representation of the system in question. Let $\mathfrak{g}$ be a matrix Lie algebra. Let $\alpha = A\,dx + B\,dy$ be a $\mathfrak{g}$-valued zero curvature representation (ZCR) for the system $\mathcal{E}$. This means that A, B are $\mathfrak{g}$-valued functions on the equation submanifold E and $D_y A - D_x B + [A, B] = 0$ holds on E. Let us introduce the associated pseudopotential P as a $\mathfrak{g}$-valued solution of the compatible system

$$P_x = [A, P] + LA, \qquad P_y = [B, P] + LB. \tag{3}$$

A recursion operator R is then a linear operator in U^k and P such that $U' = R(U, P)$ solves the linearized system $L\mathcal{E}$ whenever U does and P satisfies (3) (see [19,20]). In this way, the inverse recursion operator can be found without previous knowledge of the direct recursion operator. A remarkable aspect of this approach is that $R(U, P)$ tends to be a very simple expression.

For the above scheme to work, it is not necessary that the ZCR α a priori depends on the "spectral parameter". However, if R is a recursion operator related to the ZCR α as above, then $(R^{-1} + \mu\,\mathrm{Id})^{-1}$ is another recursion operator, associated with a ZCR α_μ which depends on μ.

3 The results

We consider vacuum Einstein equations for a space-time with two commuting Killing vectors that are orthogonal to a foliation by 2-dimensional surfaces [4,5]. Our presentation will be restricted to the case when both Killing vectors are space-like. The case when one of the Killing vectors is time-like is equivalent to ours via an appropriate complex transformation of coordinates.

As is well known, there exist coordinates x, y, z^1, z^2 such that the metric in question can be written in the form $ds^2 = 2f(x, y)\,dx\,dy + g_{ij}(x, y)\,dz^i\,dz^j$ (the Lewis [13] metric). The vacuum Einstein equations essentially reduce to

$$\left(\sqrt{\det g}\, g_x g^{-1}\right)_y + \left(\sqrt{\det g}\, g_y g^{-1}\right)_x = 0, \tag{4}$$

while f can be obtained by quadrature. Using the standard normalization $\det g = (x + y)^2$ compatible with equation (4), we parametrize g as follows: $g_{11} = (x + y)/u$, $g_{12} = (x + y)v/u$, $g_{22} = (x + y)(u^2 + v^2)/u$. Equation (4) then becomes

$$u_{xy} = \frac{u_x u_y - v_x v_y}{u} - \frac{1}{2}\frac{u_x + u_y}{x + y}, \qquad v_{xy} = \frac{v_x u_y + u_x v_y}{u} - \frac{1}{2}\frac{v_x + v_y}{x + y}. \tag{5}$$

As is well known, equation (5) has a ZCR and a Bäcklund transformation [1–3,9,16,17,22]. The ZCR reads

$$A=\frac{1}{2}\begin{pmatrix}-(\theta+1)u_x/u & (\theta+1)v_x/u^2\\ (\theta-1)v_x & (\theta+1)u_x/u\end{pmatrix},\qquad B=\frac{1}{2\theta}\begin{pmatrix}-(\theta+1)u_y/u & (\theta+1)v_y/u^2\\ (-\theta+1)v_y & (\theta+1)u_y/u\end{pmatrix},$$

where $\theta=\sqrt{(\mu+y)/(\mu-x)}$, μ being the spectral parameter.

The main result of this paper, obtained by the methods of [19,20], is as follows: If nonlocal variables p_{11}, p_{12}, p_{21} satisfy

$$\begin{aligned}
p_{11,x}&=-\frac{\theta-1}{2}v_xp_{12}+\frac{\theta+1}{2}\frac{v_x}{u^2}p_{21}-\frac{\theta+1}{2}\frac{1}{u}U_x+\frac{\theta+1}{2}\frac{u_x}{u^2}U,\\
p_{12,x}&=-(\theta+1)\frac{v_x}{u^2}p_{11}-(\theta+1)\frac{u_x}{u}p_{12}-(\theta+1)\frac{v_x}{u^3}U+\frac{\theta+1}{2}\frac{1}{u^2}V_x,\\
p_{21,x}&=(\theta-1)v_xp_{11}+(\theta+1)\frac{u_x}{u}p_{21}+\frac{\theta-1}{2}V_x,\\
p_{11,y}&=\frac{\theta-1}{2\theta}v_yp_{12}+\frac{\theta+1}{2\theta}\frac{v_y}{u^2}p_{21}+\frac{\theta+1}{2\theta}\frac{u_y}{u^2}U-\frac{\theta+1}{2\theta}\frac{1}{u}U_y,\\
p_{12,y}&=-\frac{\theta+1}{\theta}\frac{v_y}{u^2}p_{11}-\frac{\theta+1}{\theta}\frac{u_y}{u}p_{12}-\frac{\theta+1}{\theta}\frac{v_y}{u^3}U+\frac{\theta+1}{2\theta}\frac{1}{u^2}V_y,\\
p_{21,y}&=-\frac{\theta-1}{\theta}v_yp_{11}+\frac{\theta+1}{\theta}\frac{u_y}{u}p_{21}-\frac{\theta-1}{2\theta}V_y,
\end{aligned}\tag{6}$$

then

$$\begin{aligned}
U'&=2\frac{u}{\sqrt{(\mu-x)(\mu+y)}}p_{11}+\frac{1}{\sqrt{(\mu-x)(\mu+y)}}U,\\
V'&=-\frac{u^2}{\sqrt{(\mu-x)(\mu+y)}}p_{12}-\frac{1}{\sqrt{(\mu-x)(\mu+y)}}p_{21}
\end{aligned}\tag{7}$$

is a recursion operator for equation (5), namely, it sends symmetries to symmetries if the latter are viewed as solutions of the linearized system

$$\begin{aligned}
U_{xy}&=\left(\frac{u_y}{u}-\frac{1}{2(x+y)}\right)U_x+\left(\frac{u_x}{u}-\frac{1}{2(x+y)}\right)U_y-\frac{u_xu_y-v_xv_y}{u^2}U-\frac{v_y}{u}V_x-\frac{v_x}{u}V_y,\\
V_{xy}&=\frac{v_y}{u}U_x+\frac{v_x}{u}U_y-\frac{v_xu_y+u_xv_y}{u^2}U+\left(\frac{u_y}{u}-\frac{1}{2(x+y)}\right)V_x+\left(\frac{u_x}{u}-\frac{1}{2(x+y)}\right)V_y.
\end{aligned}$$

The 'direct' recursion operator for this equation seems to be missing in the literature; we can obtain it by inverting the operator (7), the result being

$$\begin{aligned}
U'&=uvp_1-up_2+(y-x)U,\\
V'&=-\tfrac{1}{2}\left(u^2-v^2\right)p_1-vp_2-\tfrac{1}{2}p_3+(y-x)V,
\end{aligned}$$

where p_1, p_2, p_3 satisfy

$$\begin{aligned}
p_{1,x}&=(x+y)\left(-2\frac{v_x}{u^3}U+\frac{1}{u^2}V_x\right),\\
p_{2,x}&=(x+y)\left(-\frac{uu_x+2vv_x}{u^3}U+\frac{1}{u}U_x+\frac{v_x}{u^2}V+\frac{v}{u^2}V_x\right),\\
p_{3,x}&=(x+y)\left(2\frac{(uu_x+vv_x)v}{u^3}U-2\frac{v}{u}U_x-2\frac{uu_x+vv_x}{u^2}V+\frac{u^2-v^2}{u^2}V_x\right),
\end{aligned}$$

$$p_{1,y}=(x+y)\left(2\frac{v_y}{u^3}U-\frac{1}{u^2}V_y\right),$$
$$p_{2,y}=(x+y)\left(\frac{uu_y+2vv_y}{u^3}U-\frac{1}{u}U_y-\frac{v_y}{u^2}V-\frac{v}{u^2}V_y\right),$$
$$p_{3,y}=(x+y)\left(-2\frac{(uu_y+vv_y)v}{u^3}U+2\frac{v}{u}U_y+2\frac{uu_y+vv_y}{u^2}V-\frac{u^2-v^2}{u^2}V_y\right).$$

It is readily seen that p_i are potentials of the linearizations [18] of the three obvious conservation laws of equation (4).

Quite unusually, neither of the recursion operators found generates an infinite series of local symmetries (and no such series is known). The action of our operators on the infinite-dimensional Geroch group of nonlocal symmetries [5, 11] remains to be investigated.

It is convenient to rewrite system (6) in triangular form. To achieve this, we introduce the Riccati pseudopotential q by

$$q_x=\frac{\theta-1}{2}v_xq^2-(\theta+1)\frac{u_x}{u}q-\frac{\theta+1}{2}\frac{v_x}{u^2},\qquad q_y=-\frac{\theta-1}{2\theta}v_yq^2-\frac{\theta+1}{2\theta}\frac{u_y}{u}q-\frac{\theta+1}{2\theta}\frac{v_y}{u^2}$$

and a nonlocal potential r by

$$r_x=(\theta-1)v_xq-(\theta+1)\frac{u_x}{u},\qquad r_y=-\frac{\theta-1}{\theta}v_yq-\frac{\theta+1}{\theta}\frac{u_y}{u}.$$

Then the inverse recursion operator assumes the form

$$U'=\frac{1}{\sqrt{(\mu-x)(\mu+y)}}\left(2uQ-2\frac{uq}{\mathrm{e}^r}R+U\right),$$
$$V'=\frac{1}{\sqrt{(\mu-x)(\mu+y)}}\left(-u^2\mathrm{e}^rP-2u^2qQ+\frac{u^2q^2-1}{\mathrm{e}^r}R\right),$$

where P, Q, R are supposed to satisfy

$$P_x=(\theta+1)\frac{q}{u}\mathrm{e}^{-r}U_x+\left(\frac{\theta+1}{2}\frac{1}{u^2}-\frac{\theta-1}{2}q^2\right)\mathrm{e}^{-r}V_x-(\theta+1)\left(\frac{qu_x}{u^2}+\frac{v_x}{u^3}\right)\mathrm{e}^{-r}U,$$
$$Q_x=-\frac{\theta+1}{2}\frac{1}{u}U_x+\frac{\theta-1}{2}qV_x+\frac{\theta+1}{2}\frac{u_x}{u^2}U-\frac{\theta-1}{2}v_x\mathrm{e}^rP,$$
$$R_x=\frac{\theta-1}{2}\mathrm{e}^rV_x+(\theta-1)v_x\mathrm{e}^rQ,$$
$$P_y=\frac{\theta+1}{\theta}\frac{q}{u}\mathrm{e}^{-r}U_y+\left(\frac{\theta+1}{2\theta}\frac{1}{u^2}+\frac{\theta-1}{2\theta}q^2\right)\mathrm{e}^{-r}V_y-\frac{\theta+1}{\theta}\left(\frac{qu_y}{u^2}+\frac{v_y}{u^3}\right)\mathrm{e}^{-r}U,$$
$$Q_y=-\frac{\theta+1}{2\theta}\frac{1}{u}U_y-\frac{\theta-1}{2\theta}qV_y+\frac{\theta+1}{2\theta}\frac{u_y}{u^2}U+\frac{\theta-1}{2\theta}v_y\mathrm{e}^rP,$$
$$R_y=-\frac{\theta-1}{2\theta}\mathrm{e}^rV_y-\frac{\theta-1}{\theta}v_y\mathrm{e}^rQ.$$

This form of the inverse recursion operator is better adapted to generation of symmetries, which is, however, beyond the scope of this paper.

Consider a non-relativistic Hamiltonian operator H in 2 dimensions consisting of a kinetic energy term plus a potential. We show that if the associated Schrödinger eigenvalue equation admits an orthogonal separation of variables, there is a calculus to describe the (in general) infinite-order differential operator symmetries of the Schrödinger equation. The calculus is formal but can be made rigorous when all functions in the eigenvaue equation are analytic. The infinite-order calculus exhibits structure that is not apparent when one studies only finite-order symmetries. The search for finite-order symmetries can then be reposed as one of looking for solutions of a coupled system of PDEs that are polynomial in certain parameters. We go further and extend the calculus to the situation where the Schrödinger equation admits a second-order symmetry operator, not necessarily associated with orthogonal separable coordinates.

1 Introduction

Consider a Schrödinger operator

$$H \equiv L_1 = \Delta_2 + V(\boldsymbol{x}),$$

where Δ_2 is the Laplace–Beltrami operator on a real or complex two-dimensional Riemannian space and $\boldsymbol{x} = (x_1, x_2)$ are orthogonal coordinates on that space such that the Schrödinger equation

$$H\Psi = E\Psi$$

separates multiplicatively in these coordinates. We here consider locally analytic solutions of this equation; application of boundary conditions is a separate step. We will introduce a calculus to describe the differential symmetry operators for this system, even those of infinite order. The question of finding finite order symmetries is reposed as a question of finding solutions of finite systems of PDEs that are polynomial in certain parameters. (See [1] where we introduced infinite-order conformal symmetry operators for the time-dependent Schrödinger equation in one space variable.) We give a number of examples where this method yields finite order differential symmetry operators. These questions as to when a system with two second-order constants of the motion, classical or quantum, (generated by an orthogonal separation of variables) admits additional polynomial constants of the motion are closely related to the concept of superintegrability [2–7]. We also consider all cases where the Schrödinger equation admits a second-order symmetry, not necessarily associated with orthogonal separable coordinates, or even separable coordinates at all. In each instance we construct additional symmetries.

2 Two-dimensional separable systems

Consider the case of orthogonal separable coordinates in a general Riemannian space. In the local separable coordinates $\{x, y\}$ the Schrödinger operator has the form

$$H = L_1 = \frac{1}{f_1(x) + f_2(y)} \left(\partial_x^2 + \partial_y^2 + v_1(x) + v_2(y)\right). \tag{1}$$

and, due to the separability, there is the invariant

$$L_2 = \frac{f_2(y)}{f_1(x) + f_2(y)} \left(\partial_x^2 + v_1(x)\right) - \frac{f_1(x)}{f_1(x) + f_2(y)} \left(\partial_y^2 + v_2(y)\right),$$

i.e., $[L_2, H] = 0$, [9,10]. We have the operator identities

$$f_1(x)H + L_2 = \partial_x^2 + v_1(x), \qquad f_2(y)H - L_2 = \partial_y^2 + v_2(y). \tag{2}$$

We look for a partial differential operator $\tilde{L}(H, L_2, x, y)$ that satisfies

$$[H, \tilde{L}] = 0. \tag{3}$$

and $[L_2, \tilde{L}] \neq 0$. We require that the invariant take the standard form

$$\tilde{L}(H, L_2, x, y) = \sum_{j,k} \left(A_{j,k}(x, y)\partial_{xy} + B_{j,k}(x, y)\partial_x + C_{j,k}(x, y)\partial_y + D_{j,k}(x, y)\right) H^j L_2^k. \tag{4}$$

Note that if the formal operators (4) contained partial derivatives in x and y of orders ≥ 2 we could use the identities (2), recursively, and rearrange terms to achieve the unique standard form (4).

Using the operator identities

$$\partial_x H = H\partial_x - \frac{f_1'}{f_1 + f_2}H + \frac{v_1'}{f_1 + f_2}, \qquad \partial_y H = H\partial_y - \frac{f_2'}{f_1 + f_2}H + \frac{v_2'}{f_1 + f_2},$$
$$\partial_x L_2 = L_2\partial_x - \frac{f_1' f_2}{f_1 + f_2}H + \frac{f_2 v_1'}{f_1 + f_2}, \qquad \partial_y L_2 = L_2\partial_y + \frac{f_1 f_2'}{f_1 + f_2}H - \frac{f_1 v_2'}{f_1 + f_2},$$

we see that

$$\begin{aligned}
&(f_1(x) + f_2(y))[H, A(x, y)\partial_{xy} + B(x, y)\partial_x + C(x, y)\partial_y + D(x, y)] \\
&\quad = (A_{xx} + A_{yy} + 2B_y + 2C_x)\partial_{xy} + (B_{xx} + B_{yy} - 2A_y v_2 + 2D_x - Av_2')\partial_x \\
&\quad + (2A_y f_2 + Af_2')\partial_x H - 2A_y\partial_x L_2 + (C_{xx} + C_{yy} - 2A_x v_1 + 2D_y - Av_1')\partial_y \\
&\quad + (2A_x f_1 + Af_1')\partial_y H + 2A_x\partial_y L_2 + (D_{xx} + D_{yy} - 2B_x v_1 - 2C_y v_2 - Bv_1' - Cv_2') \\
&\quad + (2B_x f_1 + 2C_y f_2 + Bf_1' + Cf_2')H + (2B_x - 2C_y)L_2.
\end{aligned}$$

Thus the condition (3) for the symmetries of (1) is equivalent to the system of equations

$$\partial_{xx}A_{j,k} + \partial_{yy}A_{j,k} + 2\partial_y B_{j,k} + 2\partial_x C_{j,k} = 0, \tag{5}$$
$$\begin{aligned}
&\partial_{xx}B_{j,k} + \partial_{yy}B_{j,k} - 2\partial_y A_{j,k}v_2 + 2\partial_x D_{j,k} - A_{j,k}v_2' \\
&\quad + (2\partial_y A_{j-1,k}f_2 + A_{j-1,k}f_2') - 2\partial_y A_{j,k-1} = 0,
\end{aligned} \tag{6}$$
$$\begin{aligned}
&\partial_{xx}C_{j,k} + \partial_{yy}C_{j,k} - 2\partial_x A_{j,k}v_1 + 2\partial_y D_{j,k} - A_{j,k}v_1' \\
&\quad + (2\partial_x A_{j-1,k}f_1 + A_{j-1,k}f_1') + 2\partial_x A_{j,k-1} = 0,
\end{aligned} \tag{7}$$
$$\partial_{xx}D_{j,k} + \partial_{yy}D_{j,k} - 2\partial_x B_{j,k}v_1 - 2\partial_y C_{j,k}v_2 - B_{j,k}v_1' - C_{j,k}v_2' \tag{8}$$

$$+ (2\partial_x B_{j-1,k} f_1 + 2\partial_y C_{j-1,k} f_2 + B_{j-1,k} f_1' + C_{j-1,k} f_2') + (2\partial_x B_{j,k-1} - 2\partial_y C_{j,k-1}) = 0.$$

Note that condition (4) makes sense for infinite order differential equations, in domains where the functions f_j, v_j are analytic. Indeed, one can consider H, L_2 as parameters in these equations. Then once $\tilde{L}$ is expanded as a convergent power series in these parameters, the terms are reordered so that the powers of the parameters are on the right, before they are replaced by explicit differential operators. Alternatively one can consider the operator $\tilde{L}$ as acting on a simultaneous eigenbasis of the commuting operators H and L_2, in which case the parameters are the eigenvalues. In this view we can write

$$\tilde{L}(H, L_2, x, y) = A(x, y, H, L_2)\partial_{xy} + B(x, y, H, L_2)\partial_x + C(x, y, H, L_2)\partial_y + D(x, y, H, L_2),$$

and consider $\tilde{L}$ as an at most second-order order differential operator in x, y that is analytic in the parameters H, L_2. Then the above system (5), (6), (7), (8) can be written in the more compact form

$$A_{xx} + A_{yy} + 2B_y + 2C_x = 0, \tag{9}$$
$$B_{xx} + B_{yy} - 2A_y v_2 + 2D_x - A v_2' + (2A_y f_2 + A f_2')H - 2A_y L_2 = 0, \tag{10}$$
$$C_{xx} + C_{yy} - 2A_x v_1 + 2D_y - A v_1' + (2A_x f_1 + A f_1')H + 2A_x L_2 = 0, \tag{11}$$
$$D_{xx} + D_{yy} - 2B_x v_1 - 2C_y v_2 - B v_1' - C v_2' + (2B_x f_1 + 2C_y f_2 + B f_1' + C f_2')H + (2B_x - 2C_y)L_2 = 0. \tag{12}$$

and this system has many solutions.

Remark 1. Although our derivation has implicitly assumed analyticity of A, B, C, D in H, L_2 in a neighborhood of $(0, 0)$. It is easy to show that the same equations (9)–(12) arise if these functions are analytic in the neighborhood of any point (H^0, L_2^0).

We start with a very special case

$$A \equiv 0, \quad B = X(x, H, L_2), \quad C = Y(y, H, L_2), \quad D = \tilde{X}(x, H, L_2) + \tilde{Y}(y, H, L_2). \tag{13}$$

Then the above PDEs uncouple into ODEs for X and Y, whose structure we can easily analyse. The separated equation for X can be written in the compact form

$$X''' + 4(v_1 - f_1 H - L_2)X' + 2(v_1' - f_1' H)X = -2P(H, L_2), \qquad \tilde{X} = -\frac{1}{2}X', \tag{14}$$

where the separation constant $P(H, L_2)$ is a given analytic function of its arguments. (We can take it to be a polynomial.) The first equation (14) always has solutions for any f_1, v_1, say continuously differentiable. Thus we can always construct M and it will be analytic in the parameters H, L_2. Further we have the result

Lemma 1. *Let $\Psi_1(H, L_2, x)$, $\Psi_2(H, L_2, x)$ be a basis of solutions for the equation*

$$\left(\frac{d^2}{dx^2} + v_1(x) - f_1(x)H - L_2\right)\Psi(x) = 0.$$

Then $S_1(x) = \Psi_1^2$, $S_2(x) = \Psi_1\Psi_2$, $S_3(x) = \Psi_2^2$ is a basis of solutions for the homogeneous equation

$$S''' + 4(v_1 - f_1 H - L_2)S' + 2(v_1' - f_1' H)S = 0. \tag{15}$$

Thus the general solution of the first equation (14) is a particular solution of this equation plus an arbitrary linear combination of S_1, S_2, S_3.

Similarly, the separation equation for $C = Y$ is

$$Y''' + 4(v_2 - f_2 H + L_2)Y' + 2(v_2' - f_2' H)Y = 2P(H, L_2), \qquad \tilde{Y} = -\frac{1}{2}Y'.$$

Once we have obtained X and Y, then we see that the corresponding operator L_3 commutes with H. Thus we can view L_3 as an infinite order differential symmetry operator for H. In special cases this will be a finite order operator.

It is important to note that (for $P \neq 0$) L_3 is not just a function of H and L_2. Indeed, a straightforward computation yields $[L_2, L_3] = P(H, L_2) \neq 0$. In fact, an analogous constructions to the above but based on the operator L_2 yields an operator L_4 such that $H = L_1$, L_2, L_3, L_4 satisfy the commutation relations

$$[L_1, L_2] = [L_1, L_3] = [L_2, L_4] = [L_3, L_4] = 0, \qquad [L_2, L_3] = [L_1, L_4] = P(L_1, L_2).$$

If we choose $P(L_1, L_2) = I$, the identity operator, then these are the canonical commutation relations.

Example 1. We consider Cartesian coordinates in flat space and assume that the potential is separable in these coordinates. Thus we have $f_1(x) = f_2(y) = \frac{1}{2}$ and

$$H = \partial_x^2 + \partial_y^2 + v_1(x) + v_2(y), \qquad L_2 = \frac{1}{2}(\partial_x^2 + v_1(x)) - \frac{1}{2}(\partial_y^2 + v_2(y)).$$

We look for a 3rd order constant of the motion L_3. Thus we have

$$P(H, L_2) = \sum_{j+k \leq 2} \alpha_{jk} H^j L_2^k$$

and the x-dependent part of the symmetry operator must take the form

$$M = (X_{10}\partial_x + \tilde{X}_{10})H + (X_{01}\partial_x + \tilde{X}_{01})L_2 + (X_{00}\partial_x + \tilde{X}_{00}), \qquad \tilde{X}_{jk} = -\frac{1}{2}X_{jk}'.$$

This leads to the system of equations (labeled by the powers (j, k) of $H^j L_2^k$)

$$\begin{aligned}
&(2,0) \quad X_{10}' = \alpha_{20},\\
&(1,1) \quad X_{01}' + 2X_{10}' = \alpha_{11},\\
&(0,2) \quad 2X_{01}' = \alpha_{02},\\
&(1,0) \quad -\frac{1}{2}X_{10}''' - v_1 X_{10} - 2v_1 X_{10}' + X_{00}' = \alpha_{10},\\
&(0,1) \quad -\frac{1}{2}X_{01}''' - v_1 X_{01} - 2v_1 X_{01}' + 2X_{00}' = \alpha_{01},\\
&(0,0) \quad -\frac{1}{2}X_{00}''' - v_1 X_{00} - 2v_1 X_{00}' = \alpha_{00}.
\end{aligned} \tag{16}$$

These equations are equivalent to

$$\begin{aligned}
&X_{10} = \alpha_{20}x + c_{10}, \qquad X_{01} = \frac{1}{2}\alpha_{02}x + c_{01}, \qquad \alpha_{02} + 4\alpha_{20} = 2\alpha_{11},\\
&X_{00}' = (\alpha_{20}x + c_{10})v_1' + 2\alpha_{20}v_1 + \alpha_{10},\\
&2X_{00}' = \left(\frac{1}{2}\alpha_{02}x + c_{01}\right)v_1' + \alpha_{02}v_1 + \alpha_{01}, \qquad -\frac{1}{2}X_{00}''' - v_1 X_{00} - 2v_1 X_{00}' = \alpha_{00}.
\end{aligned}$$

A very similar computation, with the same polynomial $P(H, L_2)$, yields the possibilities for $v_2(y)$, and the construction of the y-dependent part of the symmetry operator L_3. Then L_3 is a third-order quantum constant of the motion.

3 The general case

Up to now we have only considered the special case (13): $A = 0, B = X(x)$, $C = Y(y)$, $D = \tilde{X}(x) + \tilde{Y}(y)$ of conditions (9)–(12). Let us now consider the case such that $A \equiv 0$, but, otherwise, B, C, D are arbitrary. Then there is a function $G(x, y, H, L_2)$ such that

$$B = -\partial_x G, \qquad C = \partial_y G,$$

and the determining conditions simplify to

1) $G_{xxxy} + G_{xyyy} = 0$,

2) $\frac{1}{2}G_{xxxx} + 2G_{xx}v_1 + G_x v_1' - (2G_{xx}f_1 + G_x f_1')H - 2G_{xx}L_2$
$= \frac{1}{2}G_{yyyy} + 2G_{yy}v_2 + G_y v_2' - (2G_{yy}f_2 + G_y f_2')H + 2G_{yy}L_2.$

The first determining equation means that $G(x, y) = K(x, y) + F(x) + J(y)$ where F, J are arbitrary and K is harmonic: $K_{xx} + K_{yy} = 0$. This representation is unique in K, F, J, up to the addition of the harmonic separable function $\tilde{K}(x, y) = \frac{a}{2}(x^2 - y^2) + bx + cy + d$. Alternatively, we can write

$$G(x, y) = z_1(x + iy) + z_2(x - iy) + F(x) + J(y),$$

where z_1, z_2 are arbitrary analytic functions. Then only condition 2) remains to be satisfied.

Example 2. If we make the ansatz $G = X(x, H, L_2)Y(y, H, L_2)$ then, in addition to the well known angular momentum invariant, we find the following two polynomial invariants:

1. $X = \left(\frac{1}{4} + L_2\right)\cos x + s(1 + \beta H), \qquad Y = \left(\frac{1}{4} + L_2\right)\cosh y + t(1 + \xi H),$
$v_1(x) = 2s\frac{\sin x}{\cos^2 x} + \frac{a_1}{\cos^2 x}, \qquad f_1(x) = -2s\beta\frac{\sin x}{\cos^2 x} + \frac{a_2}{\cos^2 x},$
$v_2(y) = 2t\frac{\sinh y}{\cosh^2 y} + \frac{b_1}{\cosh^2 y}, \qquad f_2(y) = -2t\xi\frac{\sinh y}{\cosh^2 y} + \frac{b_2}{\cosh^2 y},$
$D = -\frac{1}{2}(\frac{1}{4} + L_2)\left(t\cos x(1 + \xi H) + s\cosh y(1 + \beta H)\right).$
2. $\tilde{L} = -2x(y^2 + 4L_2)\partial_x + 2y(x^2 - 4L_2)\partial_y + x^2 - y^2,$
$v_1(x) = \frac{1}{8}x^2 + \frac{a_1}{x^2}, \qquad f_1(x) = \frac{a_2}{x^2}, \qquad v_2(y) = \frac{1}{8}y^2 + \frac{b_1}{y^2}, \qquad f_2(y) = \frac{b_2}{y^2}.$

Example 3. Again we consider the special case of conditions (9)–(12) such that $A \equiv 0$. Now we require

$$G(x, y) = -2\log(X(x) + Y(y)) + \mathcal{F}(x) + \mathcal{J}(y) = K(x, y) + F(x) + J(y),$$

where F, J are arbitrary and K is harmonic. Then the harmonic requirement on K implies that

$$K = -2\log(X + Y) + \tilde{F}(x) + \tilde{J}(y),$$

where

$$(X')^2 = \frac{\alpha}{12}X^4 + \frac{\beta}{3}X^3 + \gamma X^2 + 2\delta X + \phi,$$
$$(Y')^2 = -\frac{\alpha}{12}Y^4 + \frac{\beta}{3}Y^3 - \gamma Y^2 + 2\delta Y - \phi,$$

$$X'' = \frac{\alpha}{6}X^3 + \frac{\beta}{2}X^2 + \gamma X + \delta, \qquad Y'' = -\frac{\alpha}{6}Y^3 + \frac{\beta}{2}Y^2 - \gamma Y + \delta.$$

Further,

$$\tilde{F}(x) = \frac{1}{3}\frac{X'''}{X'}, \qquad \tilde{J}(y) = \frac{1}{3}\frac{Y'''}{Y'},$$

and the metric and potential terms have the solution

$$v_1 - f_1 H = \frac{-\frac{a}{12}X^4 - \frac{b}{3}X^3 + \frac{b_1}{2}X^2 + \eta_1 X + \eta_2}{24(X')^2},$$
$$v_2 - f_2 H = \frac{\frac{a}{12}Y^4 - \frac{b}{3}Y^3 - \frac{b_1}{2}Y^2 + \eta_1 Y - \eta_2}{24(Y')^2}.$$

Here, α, β, γ, δ, ϕ and

$$a = a^{(1)} + a^{(2)}H, \qquad b = b^{(1)} + b^{(2)}H, \qquad b_1 = b_1^{(1)} + b_1^{(2)}H,$$
$$\eta_1 = \eta_1^{(1)} + \eta_1^{(2)}H, \qquad \eta_2 = \eta_2^{(1)} + \eta_2^{(2)}H$$

are parameters. The remaining condition is

$$\frac{1}{2}F'''' + 2F''(v_1 - f_1 H - L_2) + F'(v_1 - f_1' H) - \frac{1}{2}J'''' - 2J''(v_2 - f_2 H - L_2) - J'(v_2' - f_2' H)$$
$$= \frac{1}{36}\left(\frac{a}{2}X^2 + bX - \frac{a}{2}Y^2 + bY\right) + \frac{2}{3}\left(\frac{X'''}{X'}(v_1 - f_1 H) - \frac{Y'''}{Y'}(v_2 - f_2 H)\right)$$
$$+ \tilde{F}'(v_1' - f_1' H) - \tilde{J}'(v_2' - f_2' H).$$

The simplest family of solutions is obtained by setting $F \equiv \tilde{F}$, $J \equiv \tilde{J}$ and $\alpha = \beta = a = b = 0$.

Now we consider the general case of conditions (9)–(12). Then there are two functions $F(x, y, H, L_2)$, $G(x, y, H, L_2)$ such that

$$A = \partial_{xy}F, \qquad B = -\frac{1}{2}\partial_{xyy}F - \partial_x G, \qquad C = -\frac{1}{2}\partial_{xxy}F + \partial_y G,$$

and the determining conditions simplify to

1) $2G_{xyyy} + \frac{1}{2}F_{xyyyyy} + 2F_{xyyy}(v_2 - f_2 H + L_2) + 3F_{xyy}(v_2' - f_2' H) + F_{xy}(v_2'' - f_2'' H)$
$= -2G_{xxxy} + \frac{1}{2}F_{xxxxxy} + 2F_{xxxy}(v_1 - f_1 H - L_2)$
$+ 3F_{xxy}(v_1' - f_1' H) + F_{xy}(v_1'' - f_1'' H),$

2) $\frac{1}{2}F_{xxxxyy} + 2F_{xxyy}(v_1 - f_1 H) + F_{xxy}(v_2' - f_2' H) + \frac{1}{2}G_{xxxx}$
$+ 2G_{xx}(v_1 - f_1 H - L_2) + G_x(v_1' - f_1' H)$
$= -\frac{1}{2}F_{xxyyyy} - 2F_{xxyy}(v_2 - f_2 H) - F_{xyy}(v_1' - f_1' H) + \frac{1}{2}G_{yyyy}$
$+ 2G_{yy}(v_2 - f_2 H + L_2) + G_y(v_2' - f_2' H).$

Example 4. Consider the problem of finding all third-order symmetry operators corresponding to potentials that separate in Cartesian coordinates in Euclidean space. Then $f_1 = f_2 = \frac{1}{2}$. Third-order symmetry operators correspond to $F = F(x, y)$ and $G = g(x, y)L_1 + h(x, y)L_2 + k(x, y)$. Now let $f(x, y) = F_{xy}$, and substitute these expressions into conditions 1) and 2).

Equating coefficients of L_1^2, L_2^2, L_1L_2 in 1) and coefficients of L_1, L_2 in 2), we obtain easily the expressions

$$
\begin{aligned}
f(x,y) &= e_{00} + e_{10}x + e_{01}y + \frac{c}{2}(x^2 - y^2) + e_{11}xy,\\
g(x,y) &= c_{00} + c_{10}x + c_{01}y + c_{20}(x^2 + y^2) + c_{11}xy + c_{30}(x^3 + 3xy^2)\\
&\quad + c_{21}\left(\frac{1}{3}y^3 + x^2y\right) - \frac{c}{12}\left(x^3y + xy^3\right),\\
h(x,y) &= d_{00} + d_{10}x + d_{01}y - 2c_{20}\left(x^2 - y^2\right) + d_{11}xy - 2c_{30}\left(x^3 - 3xy^2\right)\\
&\quad - 2c_{21}\left(x^2y - \frac{1}{3}y^3\right) + \frac{c}{6}(x^3y - xy^3),
\end{aligned}
$$

where e_{ij}, c_{ij}, d_{ij}, c are constants. Equating coefficients of L_1 and L_2 in 1) and integrating, we can get expressions for k_x and k_y. The integrability condition $\partial_x k_y = \partial_y k_x$, together with equating coefficients of the constant term in 2) leads to a system of ordinary differential equations for the potential terms:

$$
\begin{aligned}
&\left(\frac{1}{2}d_{11} - c_{11} - 2c_{21}x + \frac{1}{2}cx^2\right)v_1'' + (-12c_{21} + 3cx)v_1' + 3cv_1 = -\ell_5 - \ell_4 x + \frac{1}{2}\ell_1 x^2,\\
&\left(\frac{1}{2}d_{10} - c_{10} - 4c_{20}x - 6c_{30}x^2\right)v_1'' - (12c_{20} + 36c_{30}x)v_1' - 36c_{30}v_1 = -m_2 - m_1 x + \frac{1}{2}\ell_2 x^2,\\
&(12c_{30} - e_{01} + e_{11}x)v_1'' - 3e_{11}v_1' = -q_1 x + q_3,\\
&(d_{11} - e_{00} - e_{10}x - 4c_{21}x)v_1'' + (-3e_{10} - 4c_{21})v_1' = -q_2 x + q_4,
\end{aligned}
$$

and

$$
\begin{aligned}
&\left(\frac{1}{2}d_{11} + c_{11} + 12c_{30}y - \frac{1}{6}cy^2)v_2'' + (36c_{30} - \frac{7}{3}cy\right)v_2' - 3cv_2 = -\ell_3 - \ell_2 y - \frac{1}{2}\ell_1 y^2,\\
&\left(\frac{1}{2}d_{01} + c_{01} - 4c_{20}y - 2c_{21}y^2\right)v_2'' + (12c_{20} + 12c_{21}y)v_2' + 12c_{21}v_2 = -m_3 + m_1 y + \frac{1}{2}\ell_4 y^2,\\
&(4c_{21} + e_{10} + e_{11}y)v_2'' + 3e_{11}v_2' = q_1 y + q_2,\\
&\left(e_{00} + e_{01}y - 12c_{30}y - \frac{1}{3}cy^2\right)v_2'' + \left(3e_{01} - 36c_{30} - \frac{2}{3}cy\right)v_2' = -q_3 y - q_4.
\end{aligned}
$$

Here, ℓ_j, m_j, q_j are constants. The strategy is now clear. The f, g, h expressions simply define the higher order (potential-independent) terms in the Euclidean symmetry operators and are easy to understand. For a true third-order symmetry h_x, h_y, g_x, g_y cannot all vanish. For each such choice of terms we can solve explicitly the ODEs for v_1 and v_2. Since the same v_1, v_2 have to satisfy all these equations, this puts restrictions on the constants. Then we verify that each common solution v_1, v_2 actually corresponds to a 3rd order symmetry. A tedious case-by-case procedure leads to all solutions, provided not all of the ODEs for either v_1 or v_2 are vacuous. If, say, the ODEs for v_1 are vacuous, then we must make use of the remaining integrability condition. Equating coefficients of the constant term in 1) leads to a coupled partial differential equation for the potential terms v_1, v_2

$$
\begin{aligned}
0 = \Bigg[&- 2(4c_{20} + 12c_{30}x + 4c_{21}y - cxy)v_2\\
&+ \left(\frac{1}{2}d_{10} + c_{10} + \frac{1}{2}d_{11}y + c_{11}y + 6c_{30}y^2 - \frac{1}{6}cy^3\right)v_1'
\end{aligned}
$$

$$
\begin{aligned}
&- \left(\frac{1}{2}d_{01} + c_{01} + 4c_{20}y + \frac{1}{2}d_{11}x + c_{11}x + 12c_{30}xy + 2c_{21}y^2 - \frac{1}{6}cxy^2\right) v_2' \Bigg] v_1 \\

&- \left(\frac{1}{2}d_{10} - c_{10} - 4c_{20}x + \frac{1}{2}d_{11}y - c_{11}y - 6c_{30}x^2 - 4c_{21}xy + \frac{1}{2}cx^2y\right) v_1' \Bigg] v_2 \\
&+ \Bigg[\left(4c_{20}y + 12c_{30}xy + 2c_{21}y^2 - \frac{1}{2}cxy^2\right) v_1 \\
&+ \frac{1}{2}\left(\frac{1}{2}d_{01} - c_{01} + \frac{1}{2}d_{11}x - c_{11}x - 2c_{21}x^2 + \frac{1}{6}cx^3\right) v_2 \\
&- \frac{1}{2}\left(\frac{1}{2}d_{10}y - c_{10}y - 4c_{20}xy + \frac{1}{4}d_{11}y^2 - \frac{1}{2}c_{11}y^2 - 6c_{30}x^2y - 2c_{21}xy^2 + \frac{1}{4}cx^2y^2\right) v_1' \\
&- \frac{1}{4}m_3x^2 - \frac{1}{12}x^3\ell_3 - \frac{1}{2}\left(\frac{1}{2}d_{11} + c_{11}\right) V_1 - \frac{1}{2}n_1x - \frac{1}{2}p_1 + e_{10} + cx \Bigg] v_2' \\
&+ \frac{1}{4}\left(\frac{1}{2}d_{10} + c_{10} + \frac{1}{2}d_{11}y + c_{11}y + 6c_{30}y^2 - \frac{1}{6}cy^3\right) v_1''' \\
&+ \frac{1}{4}\left(\frac{1}{2}d_{01} - c_{01} + \frac{1}{2}d_{11}x - c_{11}x - 2c_{21}x^2 + \frac{1}{6}cx^3\right) v_2'''. \qquad (17)
\end{aligned}
$$

Here, $v_j = V_j'$. This equation is complicated, but if the ODEs for v_1 are vacuous, then v_2 is a second-order polynomial in y and all constants in the above equation must be zero, except, d_{11}, d_{01}, d_{10}, ℓ_3, m_3, n_1, n_2, p_1, p_2. Thus v_1 must satisfy a simple nonlinear ODE and all solutions can be obtained. The details can be found in [12], with a different method. (That paper is focused on 3rd order invariants alone, rather than considering them as a special case of infinite-order invariants as is done here.)

Factorized solutions for the general conditions 1), 2), exist for all spaces and separable potentials.

Theorem 1. *For any v_1, v_2, f_1, f_2 there are always solutions for equations 1), 2) in which $A \not\equiv 0$, $G \equiv 0$ and F factors as $F = \mathcal{X}(x, H, L_2)\mathcal{Y}(y, H, L_2)$, where $\mathcal{X}'\mathcal{Y}' \neq 0$.*

Proof. Making the indicated substitutions, we see that the equations reduce to

$$
1)\ \ \frac{1}{2}\mathcal{X}^{(1)}\mathcal{Y}^{(5)} + 2\mathcal{X}^{(1)}\mathcal{Y}^{(3)}(v_2 - f_2H + L_2) + 3\mathcal{X}^{(1)}\mathcal{Y}^{(2)}(v_2' - f_2'H) + \mathcal{X}^{(1)}\mathcal{Y}^{(1)}(v_2'' - f_2''H)
$$

$$= \frac{1}{2}\mathcal{X}^{(5)}\mathcal{Y}^{(1)} + 2\mathcal{X}^{(3)}\mathcal{Y}^{(1)}(v_1 - f_1H - L_2) + 3\mathcal{X}^{(2)}\mathcal{Y}^{(1)}(v_1' - f_1'H)$$
$$+ \mathcal{X}^{(1)}\mathcal{Y}^{(1)}(v_1'' - f_1''H),$$
$$2)\ \ \frac{1}{2}\mathcal{X}^{(4)}\mathcal{Y}^{(2)} + \frac{1}{2}\mathcal{X}^{(2)}\mathcal{Y}^{(4)} + 2\mathcal{X}^{(2)}\mathcal{Y}^{(2)}(v_1 + v_2 - f_1H - f_2H)$$
$$+ \mathcal{X}^{(2)}\mathcal{Y}^{(1)}(v_2' - f_2'H) + \mathcal{X}^{(1)}\mathcal{Y}^{(2)}(v_1' - f_1'H) = 0.$$

Variables separate in these equations and we have

$$1a)\ \ \frac{1}{2}\mathcal{X}^{(5)} + 2\mathcal{X}^{(3)}(v_1 - f_1H - L_2) + 3\mathcal{X}^{(2)}(v_1' - f_1'H) + \mathcal{X}^{(1)}(v_1'' - f_1''H) = \alpha\mathcal{X}^{(1)},$$
$$1b)\ \ \frac{1}{2}\mathcal{Y}^{(5)} + 2\mathcal{Y}^{(3)}(v_2 - f_2H + L_2) + 3\mathcal{Y}^{(2)}(v_2' - f_2'H) + \mathcal{Y}^{(1)}(v_2'' - f_2''H) = \alpha\mathcal{Y}^{(1)},$$

where α is a constant. Similarly, if $\mathcal{X}^{(2)}\mathcal{Y}^{(2)} \neq 0$ we have the separation equations

$$2a)\ \ \frac{1}{2}\mathcal{X}^{(4)} + 2\mathcal{X}^{(2)}(v_1 - f_1H - L_2) + \mathcal{X}^{(1)}(v_1' - f_1'H) = \beta\mathcal{X}^{(2)},$$
$$2b)\ \ \frac{1}{2}\mathcal{Y}^{(4)} + 2\mathcal{Y}^{(2)}(v_2 - f_2H + L_2) + \mathcal{Y}^{(1)}(v_2' - f_2'H) = -\beta\mathcal{Y}^{(2)},$$

These equations are consistent if

$$A)\ \alpha = \beta = 0 \qquad \text{or} \qquad B)\ \alpha\mathcal{X}' = \beta\mathcal{X}''', \quad \alpha\mathcal{Y}' = -\beta\mathcal{Y}'''.$$

Now set $X = \mathcal{X}'$, $Y = \mathcal{Y}'$. Considering case A) first, we see that we have a solution of equations (9)–(12) whenever $X'Y' \neq 0$ and X and Y satisfy the ordinary differential equations

$$X''' + 4X'(v_1 - f_1H - L_2) + 2X(v_1' - f_1'H) = 0,$$
$$Y''' + 4Y'(v_2 - f_2H + L_2) + 2Y(v_2' - f_2'H) = 0,$$

essentially the same as the third order homogeneous ordinary differential equation (15).

Now suppose that $X'Y' \equiv 0$, but $X' \neq 0$. Then we have $v_2' - f_2'H = 0$ so v_2', f_2' are constants. Further, X satisfies the ordinary differential equation

$$\frac{1}{2}X'''' + 2X''(v_1 - f_1L - L_2) + 3X'(v_1' - f_1'H) + X'(v_1'' - f_1''H) = 0.$$

Finally, if $X = Y = 1$ we have $v_2'' - f_2''H = v_1'' - f_1''H = \alpha(H)$, corresponding to oscillator potentials.

For case B) we can assume $\beta = 1$. Then we find, with $\alpha = a^2$,

$$X(x) = c_1\sinh(ax) + c_2\cosh(ax), \quad f_1(x) = \frac{c_3}{X(x)^2}, \quad v_1(x) = \frac{4L_2 + 2 - a^2}{4} + \frac{c_4}{X(x)^2},$$
$$Y(y) = d_1\sin(ax) + d_2\cos(ax), \quad f_2(y) = \frac{d_3}{Y(y)^2}, \quad v_2(y) = -\frac{4L_2 + 2 - a^2}{4} + \frac{d_4}{Y(y)^2}. \qquad \blacksquare$$

Remark 2. The underlying structure of the solutions of the general equations (9)–(12) is fairly simple. Let $u_1(x, L_2) = u_1[L_2]$, $u_2(x, L_2) = u_2[L_2]$ be a basis of solutions of the separated equation

$$\left(\frac{d^2}{dx^2} + v_1(x) - f_1(x)H - L_2\right)u = 0,$$

and let $w_1(y, L_2)$, $w_2(y, L_2)$ be a basis of solutions of the separated equation

$$\left(\frac{d^2}{dy^2} + v_2(y) - f_2(y)H - L_2\right) w = 0.$$

Then for any parameter $\hat{L}_2$ the operator

$$S(\hat{L}_2) = w_2[\hat{L}_2]u_2[\hat{L}_2]\left(w_1[L_2]u_1[L_2]\partial_{xy} - w_1'[L_2]u_1[L_2]\partial_x - w_1[L_2]u_1'[L_2]\partial_y + w_1'[L_2]u_1'[L_2]\right)$$

is a symmetry operator of L_1 that maps any eigenspace of L_2 into another (generally different) eigenspace. It is not hard to characterize the space spanned by all linear combinations of functions $w_2[\hat{L}_2]u_2[\hat{L}_2]w_1[L_2]u_1[L_2]$ and this gives the equations for A. Similarly we can characterize B, C, and D. Also the solutions of (9)–(12) in the special case $A \equiv 0$ can be obtained by taking limits of the above general solutions. Indeed

$$\begin{aligned}
\tilde{S}(\hat{L}_2) = {} & (\partial_L w_2[\hat{L}_2]u_2[\hat{L}_2] + w_2[\hat{L}_2]\partial_l u_2[\hat{L}_2]) \\
& \times \left(-w_1'[L_2]u_1[L_2]\partial_x - w_1[L_2]u_1'[L_2]\partial_y + w_1'[L_2]u_1'[L_2]\right) \\
& + (\partial_L w_1[\hat{L}_2]u_1[\hat{L}_2] + w_1[\hat{L}_2]\partial_l u_1[\hat{L}_2]) \\
& \times \left(-w_2'[L_2]u_2[L_2]\partial_x - w_2[L_2]u_2'[L_2]\partial_y + w_2'[L_2]u_2'[L_2]\right) \\
& - (\partial_L w_2[\hat{L}_2]u_1[\hat{L}_2] + w_2[\hat{L}_2]\partial_l u_1[\hat{L}_2]) \\
& \times \left(-w_1'[L_2]u_2[L_2]\partial_x - w_1[L_2]u_2'[L_2]\partial_y + w_1'[L_2]u_2'[L_2]\right) \\
& - (\partial_L w_1[\hat{L}_2]u_2[\hat{L}_2] + w_1[\hat{L}_2]\partial_l u_2[\hat{L}_2]) \\
& \times \left(-w_2'[L_2]u_1[L_2]\partial_x - w_2[L_2]u_1'[L_2]\partial_y + w_2'[L_2]u_1'[L_2]\right)
\end{aligned}$$

is a symmetry with the right properties.

4 Lie form and nonorthogonal separation in two dimensions

We know that if a Hamiltonian $H = \sum_{i,j=1}^{2} g^{ij}p_ip_j$ admits a constant of the motion L that is quadratic in the momenta

$$L = \sum_{i,j=1}^{2} a^{ij}p_ip_j, \qquad \{H, L\} = 0$$

and if the roots of the determinant $|a^{ij} - \lambda g^{ij}|$ are distinct, then the eigenforms define new (separable) variables x_1, x_2 and the associated Schrödinger operator can be written in Liouville form

$$H = \frac{1}{f_1(x_1) + f_2(x_2)}\left(\partial_{x_1x_1} + \partial_{x_2x_2} + v_1(x_1) + v_2(x_2)\right).$$

However, it may be that the roots of this determinant are equal. In this case H cannot be put into Liouville form, but rather Lie form, which for a suitable choice of variables (non-separable) is

$$H = \frac{1}{x + B(y)}\left(\partial_{xy} + \frac{1}{2}K(y)\right) + \frac{1}{2}U'(y).$$

The associated quantum constant is $L = \partial_{xx} - 2yH + U(y)$.

How can we calculate a third symmetry? We look for a quantum constant of the form

$$L^o = M(H, L, y)\partial_y + N(H, L, y).$$

Applying the condition $[H, L^o] = 0$, we see that the functions M and N are of the form

$$M = \frac{1}{2H - U'(y)},$$
$$N = -\frac{1}{2}\int \frac{U''K - 2K'H + K'U' + 4B'H^2 + 4B'U'H + B'U'^2}{\sqrt{L + 2yH - U}(2H - U')^2}dy.$$

According to our operational calculus, these relations make sense when the operators are applied to a simultaneous eigenspace of H and L. Note in particular that if we consider the free Hamiltonian then L^o has the particularly simple form

$$L^o = H \int \frac{B'(y)}{\sqrt{L + 2yH}}dy - \partial_y.$$

While this appears to be only a formal expression it makes good sense for a spectral resolution analytic in a neighborhood of $(H_0, L_0) \neq (0, 0)$. Indeed, the following explicit example is informative.

Example 5. Consider the zero potential case $K = U \equiv 0$, $B(y) = y^2$. We can formally evaluate the integral in the expression for L^o by integrating by parts, and then multiply by $3H$ to obtain

$$L^i = 2(L + 2yH)^{1/2}(-L + yH) - 3H\partial_y.$$

This expression can immediately be interpreted as the differential operator

$$\hat{L} = 2\partial_x(-L + yH) - 3\partial_y H = -2\partial_x^3 + \frac{1}{x + y^2}(6y\partial_x^2\partial_y - 3\partial_y^2\partial_x)$$

which can be verified to commute with H. Indeed, if $B(y)$ is a polynomial then, through integration by parts, we can always uncover a symmetry operator of finite order. In this particular example the Hamiltonian also admits a second order symmetry operator

$$\hat{N} = x\partial_x^2 + \frac{3}{4}\partial_y^2 - \frac{3xy + \frac{1}{3}y^3}{x + y^2}\partial_x\partial_y,$$

and $[\hat{N}, L] = \hat{L}$. However, for general polynomial $B(y)$ the corresponding invariant $\hat{L}$ cannot be obtained as a commutator of other finite differential invariants.

It is clear from the method of the example that if one takes $U(y)$ as a constant and $B(y)$ and $K(y)$ as polynomials then, as before, we can generate explicit finite order differential operators that commute with H.

There is one remaining possibility for a quadratic constant of the motion in two dimensions: the constant may be associated with *nonorthogonal* separation of variables. In two dimensions there is only one case: separation in light cone (null) coordinates, [11]. For this case the Hamiltonian takes the form

$$H = \partial_z\partial_{\bar{z}} + f(\bar{z})$$

and there is a first-order symmetry operator ∂_z, so ∂_{zz} is a second-order constant of the motion. In addition there is a quadratic constant

$$L = M\partial_z + \frac{i}{2}\int \bar{z}\frac{df}{d\bar{z}}d\bar{z}.$$

where $M = i(z\partial_z - \bar{z}\partial_{\bar{z}})$.

5 Further work

A particular feature of our approach is that we can replace the partial differential operators L_1, L_2 (that do not commute with the underlying variables x, y) by scalar parameters that commute with all variables. It provides a relatively simple tool to uncover invariants. Encouraged by the theorem above, we expect to be able to characterize the structure of the algebra of infinite dimensional symmetries of L_1. Of particular interest would be conditions that would guarantee that the symmetry conditions had solutions that were polynomials in the parameters.

In future papers we will show that there is a similar calculus to express differential symmetries of the time-independent Schrödinger equation on an n-dimensional Riemannian manifold, when the equation admits R-separation in an orthogonal coordinate system. Further there is a calculus to express differential conformal symmetries of the time-dependent Schrödinger equation on an n-dimensional Riemannian manifold, when the equation admits R-separation. The time-dependent case is particularly interesting because some of its conformal symmetries can be considered as energy-shifting operators for the time-independent equations. These energy-shifting operators are usually of infinite order, but appear first order in our canonical form. They correspond to raising and lowering operators in the equations of mathematical physics.

E-mail: *morozov@sfti.snz.ru*

Applications of Cartan's equivalence method to symmetries of differential equations are considered. The examples include interrelations between the nonlinear acoustics equations, and the solutions of equivalence problems for the classes of linear parabolic equations and nonlinear wave equations.

Introduction

In this work we consider applications of Élie Cartan's structure theory of Lie pseudo-groups to symmetry groups of differential equations. This approach allows to solve equivalence problems for classes of differential equations and to find contact transformations mapping equivalent equations into each other. Also, it allows to obtain all differential invariants of symmetry groups for differential equations without analysis of over-determined systems of partial differential equations.

Definition 1 ([20, 13]). A *pseudo-group* $\mathcal{G}$ on a manifold M is a collection of local diffeomorphisms of M, which is closed under composition *when defined*, contains an identity and is closed under inverse. A *Lie pseudo-group* is a pseudo-group whose diffeomorphisms are local analytic solutions of an involutive system of partial differential equations.

Example 1. The pseudo-group of conformal transformations in $\mathbb{R}^2$ consists of local mappings $(x, y) \mapsto (X, Y)$ satisfying the Cauchy–Riemann equations $X_x = Y_y$, $X_y = -Y_x$.

É. Cartan developed an approach to study Lie pseudo-groups by means of exterior differential forms. He showed that for every Lie pseudo-group $\mathcal{G}$ acting on a manifold M there exists a finite-dimensional Lie group H and a set of 1-forms $\Omega = \{\omega^1, \dots, \omega^s\}$ on a direct product $M \times H$ such that a transformation $\Delta : M \to M$ belongs to $\mathcal{G}$ if and only if the forms Ω are invariant under a lift $\hat{\Delta} : M \times H \to M \times H$. The forms Ω are called a *moving coframe* or *tautological forms* for the pseudo-group $\mathcal{G}$.

Example 1 (continued). For the pseudo-group of conformal transformations in $\mathbb{R}^2$ we can take the moving coframe $\omega^1 = a\,dx - b\,dy$, $\omega^2 = b\,dx + a\,dy$ on $\mathbb{R}^2 \times H$, where H is a Lie group of non-degenerate matrices of the form $\begin{pmatrix} a & -b \\ b & a \end{pmatrix}$.

Taking differentials of the tautological forms, we obtain Cartan's *structure equations* for the pseudo-group

$$d\omega^i = A^i_{\alpha k}\,\eta^\alpha \wedge \omega^k + T^i_{jk}\,\omega^j \wedge \omega^k,$$

where $A^i_{\alpha k}$, as usual, are constants, the *torsion coefficients* T^i_{jk} are invariants of the pseudo-group, and η^α are linear combinations of Maurer–Cartan forms for the group H and the forms Ω. Cartan gave an explicit, practical test for involutivity of moving coframes. The test deals with ranks of matrices constructed from $A^i_{\alpha k}$. For non-involutive coframes Cartan's prolongation procedure allows us to obtain an involutive coframe after a finite number of extensions of the group H.

Example 1 (continued). The structure equations for the pseudo-group of conformal transformations are $d\omega^1 = \pi_1 \wedge \omega^1 - \pi^2 \wedge \omega^2$, $d\omega^2 = \pi_2 \wedge \omega^1 + \pi^1 \wedge \omega^2$, where $\pi_1 = (a\,da + b\,db)\,(a^2 + b^2)^{-1} + t_1\,\omega^1 + t_2\,\omega^2$, $\pi_2 = (-b\,da + a\,db)\,(a^2 + b^2)^{-1} - t_2\,\omega^1 + t_1\,\omega^2$, while t_1 and t_2 are free parameters.

Full details of Cartan's method can be found in [1–3, 17].

1 Contact transformations

Using Cartan's method, we can find a moving coframe for the pseudo-group $Cont(J^1(\mathcal{E}))$ of contact transformations on a bundle $J^1(\mathcal{E})$ of first-order jets of sections of $\mathcal{E} = \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$. In the local coordinates $(x^i, u^\alpha, p_i^\alpha)$, $i \in \{1, \dots, n\}$, $\alpha \in \{1, \dots, m\}$, a contact transformation $\Delta : J^1(\mathcal{E}) \to J^1(\mathcal{E})$, $\Delta : (x^i, u^\alpha, p_i^\alpha) \mapsto (\overline{x}^i, \overline{u}^\alpha, \overline{p}_i^\alpha)$, is defined by the requirement to map the *contact forms* $\vartheta^\alpha = du^\alpha - p_i^\alpha\,dx^i$ into linear combinations of the contact forms: $\Delta^*\overline{\vartheta}^\alpha = d\overline{u}^\alpha - \overline{p}_i^\alpha\,d\overline{x}^i = \zeta_\beta^\alpha(x, u, p)\,\vartheta^\beta$ for appropriate functions ζ_β^α on $J^1(\mathcal{E})$.

As it is shown in [14], we can take the following moving coframe for $Cont(J^1(\mathcal{E}))$:

$$\Theta^\alpha = a_\beta^\alpha\,(du^\beta - p_j^\beta\,dx^j), \quad \Xi^i = c_\beta^i\,\Theta^\beta + b_j^i\,dx^j, \quad \Sigma_i^\alpha = f_{i\beta}^\alpha\,\Theta^\beta + g_{ij}^\alpha\,\Xi^j + a_\beta^\alpha\,B_i^j\,dp_j^\beta. \tag{1}$$

These forms are defined on $J^1(\mathcal{E}) \times H$, where H is the Lie group of block lower triangular matrices

$$\begin{pmatrix} a_\beta^\alpha & 0 & 0 \\ c_\gamma^i\,a_\beta^\gamma & b_j^i & 0 \\ (f_{i\gamma}^\alpha + g_{ik}^\alpha\,c_\gamma^k)\,a_\beta^\gamma & g_{ik}^\alpha\,b_j^k & a_\beta^\alpha\,B_i^j \end{pmatrix},$$

and the parameters a_β^α, b_j^i, c_β^i, $f_{i\beta}^\alpha$, and g_{ij}^α obey the requirements $\det\left(a_\beta^\alpha\right) \neq 0$, $\det\left(b_j^i\right) \neq 0$, $b_k^i\,B_j^k = \delta_j^i$, and $g_{ij}^\alpha = g_{ji}^\alpha$. It is easy to verify directly that Δ is a contact transformation whenever (1) is invariant under an action of a lift of Δ on $J^1(\mathcal{E}) \times H$. The structure equations for the lifted coframe (1) have the form

$$\begin{aligned} &d\Theta^\alpha = \Phi_\beta^\alpha \wedge \Theta^\beta + \Xi^k \wedge \Sigma_k^\alpha, \qquad d\Xi^i = \Psi_k^i \wedge \Xi^k + \Pi_\gamma^i \wedge \Theta^\gamma, \\ &d\Sigma_i^\alpha = \Phi_\gamma^\alpha \wedge \Sigma_i^\gamma - \Psi_i^k \wedge \Sigma_k^\alpha + \Lambda_{i\beta}^\alpha \wedge \Theta^\beta + \Upsilon_{ij}^\alpha \wedge \Xi^j, \end{aligned} \tag{2}$$

where Φ_β^α, Ψ_k^i, Π_γ^i, $\Lambda_{i\beta}^\alpha$, and Υ_{ij}^α are appropriate 1-forms on $J^1(\mathcal{E}) \times H$. From these equations it follows that the moving coframe (1) is involutive. The structure equations (2) remain unchanged if we make the following change of the forms Φ_β^α, Ψ_k^i, Π_γ^i, $\Lambda_{i\beta}^\alpha$, and Υ_{ij}^α:

$$\begin{aligned} &\Phi_\beta^\alpha \mapsto \Phi_\beta^\alpha + K_{\beta\gamma}^\alpha\,\Theta^\gamma, \qquad \Psi_k^i \mapsto \Psi_k^i + L_{kj}^i\,\Xi^j + M_{k\gamma}^i\,\Theta^\gamma, \\ &\Pi_\gamma^i \mapsto \Pi_\gamma^i + M_{k\gamma}^i\,\Xi^k + N_{\gamma\epsilon}^i\,\Theta^\epsilon, \\ &\Lambda_{i\beta}^\alpha \mapsto \Lambda_{i\beta}^\alpha + P_{i\beta\gamma}^\alpha\,\Theta^\gamma + Q_{i\beta k}^\alpha\,\Xi^k + K_{\gamma\beta}^\alpha\,\Sigma_i^\gamma - M_{i\beta}^k\,\Sigma_k^\alpha, \\ &\Upsilon_{ij}^\alpha \mapsto \Upsilon_{ij}^\alpha + Q_{i\beta j}^\alpha\,\Theta^\beta + R_{ijk}^\alpha\,\Xi^k - L_{ij}^k\,\Sigma_k^\alpha, \end{aligned} \tag{3}$$

where $K_{\beta\gamma}^\alpha$, L_{kj}^i, $M_{k\gamma}^i$, $N_{\gamma\epsilon}^i$, $P_{i\beta\gamma}^\alpha$, $Q_{i\beta k}^\alpha$, and R_{ijk}^α are arbitrary functions on $J^1(\mathcal{E}) \times H$ satisfying the symmetry conditions $K_{\beta\gamma}^\alpha = K_{\beta\gamma}^\alpha$, $L_{kj}^i = L_{jk}^i$, $N_{\gamma\epsilon}^i = N_{\epsilon\gamma}^i$, $P_{i\beta\gamma}^\alpha = P_{i\gamma\beta}^\alpha$, $Q_{i\beta k}^\alpha = Q_{k\beta i}^\alpha$, $R_{ijk}^\alpha = R_{ikj}^\alpha = R_{jik}^\alpha$.

Another approach to construction of 1-forms characterizing contact transformations is presented in [18].

2 Symmetries of differential equations

Symmetry groups of differential equations are sub-groups of pseudo-groups of contact transformations. Therefore Cartan's method of equivalence is applicable to finding tautological forms for these symmetry groups. We briefly outline this approach, [4, 14].

Every partial differential equation (PDE) can be transformed into an equivalent PDE of the first order by adding appropriate new variables, [20, th. 3.3.1], [6, § 17.4]. Therefore we take a PDE $\mathcal{R}$ of the first order. $\mathcal{R}$ is a sub-bundle in $J^1(\mathcal{E})$. Let $Sym(\mathcal{R})$ be the group of contact symmetries for $\mathcal{R}$. It consists of all the contact transformations on $J^1(\mathcal{E})$ mapping $\mathcal{R}$ to itself. Let $\iota : \mathcal{R} \to J^1(\mathcal{E})$ be an embedding. The tautological forms of $Sym(\mathcal{R})$ are restrictions of the lifted coframe (1) on $\mathcal{R}$: $\theta^\alpha = \iota^*\Theta^\alpha$, $\xi^i = \iota^*\Xi^i$, and $\sigma_i^\alpha = \iota^*\Sigma_i^\alpha$ (for brevity we identify the map $\iota \times id : \mathcal{R} \times H \to J^1(\mathcal{E}) \times H$ with $\iota : \mathcal{R} \to J^1(\mathcal{E})$). The forms θ^α, ξ^i, and σ_i^α have some linear dependencies, i.e., there exists a non-trivial set of functions S_α, T_i, and U_α^i on $\mathcal{R} \times H$ such that $S_\alpha\,\theta^\alpha + T_i\,\xi^i + U_\alpha^i\,\sigma_i^\alpha \equiv 0$. These functions are lifted invariants of $Sym(\mathcal{R})$. Setting them equal to appropriate constants allows us to specify some parameters a_β^α, b_j^i, c_β^i, $f_{i\beta}^\alpha$, and g_{ij}^α of the group H as functions of the coordinates on $\mathcal{R}$ and the other group parameters.

After these normalizations, some restrictions of the forms $\phi_\beta^\alpha = \iota^*\Phi_\beta^\alpha$, $\psi_k^i = \iota^*\Psi_k^i$, and $\pi_\beta^i = \iota^*\Pi_\beta^i$, or some their linear combinations, become semi-basic, i.e., they do not include the differentials of the parameters of H. From (3), we have the following statements: (i) if ϕ_β^α is semi-basic, then its coefficients at σ_j^γ and ξ^j are lifted invariants of $Sym(\mathcal{R})$; (ii) if ψ_k^i or π_β^i are semi-basic, then their coefficients at σ_j^γ are lifted invariants of $Sym(\mathcal{R})$. Setting these invariants equal to some constants, we get specifications of some more parameters of H as functions of the coordinates on $\mathcal{R}$ and the other group parameters.

More lifted invariants can appear as essential torsion coefficients in the reduced structure equations

$$d\theta^\alpha = \phi_\beta^\alpha \wedge \theta^\beta + \xi^k \wedge \sigma_k^\alpha, \qquad d\xi^i = \psi_k^i \wedge \xi^k + \pi_\gamma^i \wedge \theta^\gamma,$$
$$d\sigma_i^\alpha = \phi_\gamma^\alpha \wedge \sigma_i^\gamma - \psi_i^k \wedge \sigma_k^\alpha + \lambda_{i\beta}^\alpha \wedge \theta^\beta + \upsilon_{ij}^\alpha \wedge \xi^j.$$

After normalizing these invariants and repeating the process, two outputs are possible. In the first case, the reduced lifted coframe appears to be involutive. Then this coframe is the desired set of tautological forms for $Sym(\mathcal{R})$. In the second case, when the reduced lifted coframe does not satisfy Cartan's test, we should use the procedure of prolongation, [17, ch. 12].

Another approach to find structure equations, but not tautological forms, for symmetry groups of PDEs is given in [12, 13].

3 Interrelations between the Khokhlov–Zabolotskaya equation and the short wave gas dynamics equation

Consider two equations: the Khokhlov–Zabolotskaya equation, [23, ch. 3, § 5.3], [21], in the potential form

$$v_x = u_y, \qquad v_y = u_t + u\,u_x, \tag{4}$$

and the short wave gas dynamics equation, [6, § 23.4], [5],

$$v_x = u_y, \qquad v_y = u_t + (u + x)\,u_x + k\,u. \tag{5}$$

The moving coframe method gives the following structure equations for the symmetry pseudo-group of (4):

$$
\begin{aligned}
&d\theta^1 = \eta_1 \wedge \theta^1 + \xi^1 \wedge \sigma_1^1 + \xi^2 \wedge \sigma_2^1 + \xi^3 \wedge \sigma_3^1,\\
&d\theta^2 = \frac{3}{2}\,\eta_1 \wedge \theta^1 + \eta_3 \wedge \theta^1 + \xi^1 \wedge \sigma_1^2 + \xi^2 \wedge \sigma_3^1 + \xi^3 \wedge \sigma_1^1 + \xi^3 \wedge \sigma_2^1,\\
&d\xi^1 = \eta_2 \wedge \xi^1,\\
&d\xi^2 = -\eta_1 \wedge \xi^1 + \eta_1 \wedge \xi^2 + \eta_2 \wedge \xi^2 - \eta_3 \wedge \xi^3 - \theta^1 \wedge \xi^1,\\
&d\xi^3 = \frac{1}{2}\,\eta_1 \wedge \xi^3 + \eta_2 \wedge \xi^3 - 2\,\eta_3 \wedge \xi^1,\\
&d\sigma_1^1 = \eta_1 \wedge \big(\sigma_1^1 + \sigma_2^1\big) - \eta_2 \wedge \sigma_1^1 + 2\,\eta_3 \wedge \sigma_3^1 + \eta_4 \wedge \xi^3 + \eta_5 \wedge \xi^2 + \eta_6 \wedge \xi^1 - \theta^1 \wedge \sigma_2^1,\\
&d\sigma_2^1 = -\eta_2 \wedge \sigma_2^1 + \eta_5 \wedge \xi^1,\\
&d\sigma_3^1 = \frac{1}{2}\,\eta_1 \wedge \sigma_3^1 - \eta_2 \wedge \sigma_3^1 + \eta_3 \wedge \sigma_2^1 + \eta_4 \wedge \xi^1 + \eta_5 \wedge \xi^3,\\
&d\sigma_1^2 = \eta_1 \wedge \left(\sigma_3^1 + \frac{1}{2}\,\sigma_1^2\right) - \eta_2 \wedge \sigma_1^2 + \eta_3 \wedge \big(3\,\sigma_1^1 + 2\,\sigma_2^1\big) + \eta_4 \wedge \xi^2 + \eta_5 \wedge \xi^3 + \eta_6 \wedge \xi^3\\
&\qquad + \eta_7 \wedge \xi^1 - 3\,\theta^2 \wedge \sigma_2^1,\\
&d\eta_1 = 2\,\xi^1 \wedge \sigma_2^1,\\
&d\eta_2 = -3\,\xi^1 \wedge \sigma_2^1,\\
&d\eta_3 = \frac{1}{2}\,\eta_1 \wedge \eta_3 + \xi^1 \wedge \sigma_3^1 + \xi^3 \wedge \sigma_2^1,\\
&d\eta_4 = \pi_1 \wedge \xi^1 + \pi_2 \wedge \xi^3 + \frac{1}{2}\,\eta_1 \wedge \eta_4 - 2\,\eta_2 \wedge \eta_4 + 3\,\eta_3 \wedge \eta_5 - 3\sigma_2^1 \wedge \sigma_3^1,\\
&d\eta_5 = \pi_2 \wedge \xi^1 - 2\,\eta_2 \wedge \eta_5,\\
&d\eta_6 = \pi_1 \wedge \xi^3 + \pi_2 \wedge \xi^2 + \pi_3 \wedge \xi^1 + 2\,\eta_1 \wedge \eta_5 + \eta_1 \wedge \eta_6 - 2\,\eta_2 \wedge \eta_6 + 4\,\eta_3 \wedge \eta_4 + 6\,\sigma_1^1 \wedge \sigma_2^1,\\
&d\eta_7 = \pi_1 \wedge \xi^2 + \pi_2 \wedge \xi^3 + \pi_3 \wedge \xi^3 + \pi_4 \wedge \xi^1 + 2\,\eta_1 \wedge \eta_4 + \frac{3}{2}\,\eta_1 \wedge \eta_7 - 2\,\eta_2 \wedge \eta_7 + 4\,\eta_3 \wedge \eta_5\\
&\qquad + 5\,\eta_3 \wedge \eta_6 - \eta_4 \wedge \theta^1 + 3\,\eta_5 \wedge \theta^2 + 3\,\sigma_1^1 \wedge \sigma_3^1 - 9\,\sigma_2^1 \wedge \sigma_1^2.
\end{aligned}
\tag{6}
$$

The structure of symmetry pseudo-group of the equation (5) depends on the value of the parameter k. Particularly, if $k = -2$ or $k = -\frac{1}{2}$, the pseudo-group has exactly the same structure equations (6) but with different 1-forms θ^1, θ^2, ξ^1, ξ^2, ξ^3, σ_1^1, σ_2^1, σ_3^1, σ_1^2, η_1, …, η_7, π_1, …, π_4. Therefore, in the cases $k = -2$ or $k = -\frac{1}{2}$ there exist transformations mapping equation (5) into equation (4).

For the other values of k the structure equations for the symmetry pseudo-group of equation (5) have the form

$$
\begin{aligned}
&d\theta^1 = \eta_1 \wedge \theta^1 + \xi^1 \wedge \sigma_1^1 + \xi^2 \wedge \sigma_2^1 + \xi^3 \wedge \sigma_3^1,\\
&d\theta^2 = \frac{3}{2}\,\eta_1 \wedge \theta^1 + \eta_2 \wedge \theta^1 + \xi^1 \wedge \sigma_1^2 + \xi^2 \wedge \sigma_3^1 + \xi^3 \wedge \sigma_1^1 + \xi^3 \wedge \sigma_2^1,\\
&d\xi^1 = 0,\\
&d\xi^2 = \eta_1 \wedge \big(\xi^2 - \xi^1\big) - \eta_2 \wedge \xi^3 - \theta^1 \wedge \xi^1 + E\,\xi^1 \wedge \xi^2,\\
&d\xi^3 = \frac{1}{2}\,\eta_1 \wedge \xi^3 - 2\,\eta_2 \wedge \xi^1 + E\,\xi^1 \wedge \xi^3,\\
&d\sigma_1^1 = \eta_1 \wedge \big(\sigma_1^1 + \sigma_2^1\big) + 2\,\eta_2 \wedge \sigma_3^1 + \eta_3 \wedge \xi^3 + \eta_4 \wedge \xi^1 - \theta^1 \wedge \sigma_2^1 + E\,\xi^2 \wedge \sigma_2^1,\\
&d\sigma_2^1 = 0,
\end{aligned}
$$

$$
\begin{aligned}
d\sigma_3^1 &= \frac{1}{2}\,\eta_1\wedge\sigma_3^1+\eta_2\wedge\sigma_2^1+\eta_3\wedge\xi^1-E\,\xi^1\wedge\sigma_3^1+E\,\xi^3\wedge\sigma_2^1,\\
d\sigma_1^2 &= \eta_1\wedge\sigma_3^1+\frac{3}{2}\,\eta_1\wedge\sigma_1^2+3\,\eta_2\wedge\sigma_1^1+2\,\eta_2\wedge\sigma_2^1+\eta_3\wedge\xi^2+\eta_4\wedge\xi^3+\eta_5\wedge\xi^1\\
&\quad+\frac{1}{9}\,\theta_1\wedge\xi^3-3\,\theta_2\wedge\sigma_2^1+E\,\xi^3\wedge\left(\sigma_1^1+\sigma_2^1\right),\\
d\eta_1 &= 2\,\xi^1\wedge\sigma_2^1,\\
d\eta_2 &= \frac{1}{2}\,\eta_1\wedge\eta_2-\frac{1}{9}\,\xi^1\wedge\xi^3+\xi^1\wedge\sigma_3^1+\xi^3\wedge\sigma_2^1,\\
d\eta_3 &= \pi_1\wedge\xi^1+\frac{1}{2}\,\eta_1\wedge\eta_3-3\,E\,\eta_2\wedge\sigma_2^1+\left(\frac{1}{9}-2\,E^2\right)\,\xi^3\wedge\sigma_2^1-3\,\sigma_2^1\wedge\sigma_3^1,\\
d\eta_4 &= \pi_1\wedge\xi^3+\pi_2\wedge\xi^1+\eta_1\wedge\eta_4-E\,\eta_1\wedge\sigma_2^1+4\,\eta_2\wedge\eta_3+2\,E\,\eta_2\wedge\sigma_3^1-E\,\eta_3\wedge\xi^3\\
&\quad-E\,\theta^1\wedge\sigma_2^1-E^2\,\xi^2\wedge\sigma_2^1+\frac{2}{9}\,\xi^3\wedge\sigma_3^1+3\,\sigma_1^1\wedge\sigma_2^1\\
d\eta_5 &= \pi_1\wedge\xi^2+\pi_2\wedge\xi^3+\pi_3\wedge\xi^1+2\,\eta_1\wedge\eta_3+\frac{3}{2}\,\eta_1\wedge\eta_5+E\,\eta_1\wedge\sigma_3^1+5\,\eta_2\wedge\eta_4\\
&\quad+\frac{2}{9}\,\eta_2\wedge\theta^1-2\,E\,\eta_2\wedge\left(\sigma_1^1+\sigma_2^1\right)-\eta_3\wedge\theta^1-E\,\eta_3\wedge\xi^2-2\,E\,\eta_4\wedge\xi^3-\frac{1}{9}\,E\,\theta^1\wedge\xi^3\\
&\quad+\left(\frac{4}{9}-E^2\right)\,\xi^3\wedge\sigma_1^1+\left(\frac{2}{9}-E^2\right)\,\xi^3\wedge\sigma_2^1+3\,\sigma_1^1\wedge\sigma_3^1-6\,\sigma_2^1\wedge\sigma_1^2,
\end{aligned}
$$

where $E=\frac{1}{3}\,(9\,u_x+4\,k+5)\,(2\,k^2+5\,k+2)^{-1/2}$. This function is an invariant of the pseudo-group. Since $dE=3\,\sigma_2^1$, it follows that all the derived invariants are constants, and the classifying manifold of the pseudo-group, i.e., the manifold parameterized by differential invariants, is a line. Thus for every two equations (5) such that $(k+2)\,(k+2^{-1})\neq 0$ the classifying manifolds of their symmetry pseudo-groups (locally) overlap. So these equations are equivalent under a contact transformation, [17, th. 15.12]. For example, we can take $k=0$ for one of the equations.

The knowledge of invariant 1-forms defining the symmetry pseudo-groups allows us to find the transformations explicitly.

Theorem 1. *If $k=-2$, then the transformation*

$$
\begin{aligned}
&\tilde t=t,\qquad \tilde x=\exp\left(\frac{4}{3}\,t\right)\,\left(x+\frac{1}{6}\,y^2\right),\qquad \tilde y=\exp\left(\frac{2}{3}\,t\right)\,y,\\
&\tilde u=\exp\left(\frac{4}{3}\,t\right)\,\left(u+\frac{1}{3}\,x-\frac{1}{18}\,y^2\right),\qquad \tilde v=\mathrm{e}^{2\,t}\,\left(v-\frac{1}{3}\,y\,u-\frac{2}{9}\,x\,y+\frac{2}{81}\,y^3\right)
\end{aligned}
$$

maps equation (4) *into equation* (5) *written in the tilded variables. In the case $k=-\frac{1}{2}$ the transformation between* (4) *and* (5) *has the form*

$$
\begin{aligned}
&\tilde t=t,\quad \tilde x=\exp\left(\frac{2}{3}\,t\right)\,\left(x+\frac{1}{12}\,y^2\right),\qquad \tilde y=\exp\left(\frac{1}{3}\,t\right)\,y,\\
&\tilde u=\exp\left(\frac{2}{3}\,t\right)\,\left(u-\frac{1}{3}\,x-\frac{1}{18}\,y^2\right),\qquad \tilde v=\mathrm{e}^{t}\,\left(v-\frac{1}{6}\,y\,u-\frac{1}{18}\,x\,y+\frac{1}{324}\,y^3\right).
\end{aligned}
$$

The transformation

$$
\begin{aligned}
&\tilde t=\frac{(3\,\lambda+1)\,(3\,\lambda+2)}{2\,(2\,\lambda+1)}\,t,\qquad \tilde x=\frac{(2\,\lambda+1)\,\mathrm{e}^{2\lambda t}}{2\,(3\lambda+1)(3\lambda+2)}\,(4\,x+\lambda^2\,y),\qquad \tilde y=\mathrm{e}^{\lambda t}\,y,\\
&\tilde u=\frac{(2\lambda+1)\,\mathrm{e}^{2\lambda t}}{2(3\lambda+1)^2(3\lambda+2)^2}\,\left(8(2\lambda+1)u-\lambda(\lambda+1)(4x-(5\lambda+2)y^2)\right),\\
&\tilde v=\frac{(2\lambda+1)^2\mathrm{e}^{3\lambda t}}{(3\lambda+1)^3(3\lambda+2)^2}\,\left(24v-12\lambda(2\lambda+1)(u+(\lambda+1)x)-\lambda^2(\lambda+1)(5\lambda+2)y^3\right),
\end{aligned}
$$

where $\lambda=\frac{2}{9}\left(((k+2)(k+2^{-1}))^{1/2}+k-1\right)$*, maps equation* (5) *with* $k\notin\{-2,-2^{-1}\}$ *into this equation with* $k=0$ *(written in tilded variables).*

4 Equivalence of linear parabolic equations

The similar but more complicate analysis gives the solution of the contact equivalence problem for the class of linear parabolic equations (LPEs), [11, V.3, p. 492–523], [19],

$$u_{xx}=T(t,x)\,u_t+X(t,x)\,u_x+U(t,x)\,u. \tag{7}$$

All these equations have infinite-dimensional symmetry pseudo-groups, whose structure depends on the coefficients of equations. For simplicity of notation we consider the following normal form $u_{xx}=u_t+H(t,x)\,u$, while the results are valid for the original equations as well. The solution of the equivalence problem in terms of the coefficients of equations (7) is given in [15].

Define the functions

$$I=-(H_{xxx})^{1/5},\qquad J_1=-\frac{2}{5}\,H_{xxxx}\,(H_{xxx})^{-6/5},$$

$$J_2=\frac{1}{2}\,\left(2\,I\,(J_{1,x}\,J_{1,tx}-J_{1,t}\,J_{1,xx})-2\,I_t\,J_{1,x}^2+I^2\,J_1\,J_{1,t}\,J_{1,x}\right)\,I^{-3}\,J_{1,x}^{-1},$$

$$\begin{aligned}J_3=-\frac{1}{8}\,&\left(I^4J_1^2J_{1,t}^2-4II_{tt}J_{1,x}^2-8I^2J_{1,x}^2H_{xx}+2I^3J_{1,x}J_{1,t}^2+8I_t^2J_{1,x}^2-2I^3J_1J_{1,t}J_{1,tx}\right.\\&\left.-2I^2J_1I_tJ_{1,t}J_{1,x}+2I^3J_1J_{1,x}J_{1,tt}-2I^5J_1J_2J_{1,t}J_{1,x}\right)\,I^{-6}\,J_{1,x}^{-2},\end{aligned}$$

$$J_4=\left(2II_{tt}J_{1,x}-4I^6J_3J_{1,x}+4I^2J_{1,x}H_{xx}-I^3J_{1,t}+2I^3J_1J_{1,x}H_x-4I_t^2J_{1,x}\right)\,I^{-6}\,J_1^{-1}\,J_{1,x}^{-1},$$

$$L_0=\left(2I^2H_{xx}+I^3J_1H_x+II_{tt}-2I_t^2\right)\,I^{-2}J_{1,t}^{-1},\qquad L_1=(L_{0,x}-I_t)\,I^{-3},$$

$$L_2=\frac{1}{2}\,\left(2IL_{0,t}+IJ_1L_0^2+4I^2H_x-2I^3L_0L_1-4L_0I_t\right)\,I^{-5},$$

$$M_0=-2\,M_{1,t}\,(3J_1M_1+2)^{-2},\quad M_1=\frac{1}{2}\,\left(II_{tt}+2IH_{xx}+I^3J_1H_x-2I_t^2\right)\,I^{-6},$$

$$M_2=(M_{0,x}-I_t)\,I^{-3},\qquad M_3=\frac{1}{8}\left(2IM_{0,t}-2I^3M_0M_2-4M_0I_t+IJ_1M_0^2+4I^2H_x\right)I^{-5}.$$

Then we have

Theorem 2. *The class of LPEs is divided into the five subclasses* $\mathcal{P}_1,\mathcal{P}_2,\dots,\mathcal{P}_5$ *invariant under an action of the pseudo-group of contact transformations:*

$\mathcal{P}_1$ *consists of all LPEs such that* $I=0$*;*

$\mathcal{P}_2$ *consists of all LPES such that* $I\neq0$ *and* $J_{1x}\neq0$*;*

$\mathcal{P}_3$ *consists of all LPEs such that* $I\neq0$*,* $J_{1x}=0$*, and* $J_{1t}\neq0$*;*

$\mathcal{P}_4$ *consists of all LPEs such that* $I\neq0$*,* $J_1=m=\mathrm{const}$*, and* $3\,m\,M_1\neq-2$*;*

$\mathcal{P}_5$ *consists of all LPEs such that* $I\neq0$*,* $J_1=m=\mathrm{const}$*, and* $3\,m\,M_1=-2$*.*

Every equation from the subclass $\mathcal{P}_1$ *is equivalent to the linear heat equation* $u_{xx}=u_t$*.*

Two equations from $\mathcal{P}_2$ *are locally equivalent to each other if and only if they have the same functional dependencies among the differential invariants* J_1*,* J_2*,* J_3*,* J_4*, and their invariant derivatives.*

Two equations from $\mathcal{P}_3$ *are locally equivalent to each other if and only if they have the same functional dependencies among the differential invariants* J_1*,* L_1*,* L_2*, and their invariant derivatives.*

Two equations from $\mathcal{P}_4$ *are locally equivalent to each other if and only if they have the same functional dependencies among the differential invariants* M_1*,* M_2*,* M_3*, and their invariant derivatives.*

Every equation from the subclass $\mathcal{P}_5$ *is locally equivalent to the equation* $u_{xx}=u_t+\tilde m\,x^{-2}\,u$ *provided* $\tilde m=-4/(3\,m^5)$*.*

The expression of the function I in terms of the coefficients of equations (7) and the necessary and sufficient condition for equivalence to the linear heat equation are found in [10]. Some particular cases of invariants – so-called Laplace type invariants – are found in [9]. Numerous examples of equations (7) from the first subclass are given in [10, 22].

5 Equivalence of nonlinear wave equations

We outline the solution of the contact equivalence problem for the following class of nonlinear wave equations

$$u_t = a(x,u)\,v_x, \qquad v_t = b(x,u)\,u_x. \tag{8}$$

As it is shown in [8], these equations are equivalent to the class of equations $w_{tt} = f(x,w_x)\,w_{xx} + g(x,w_x)$ studied in [7]. In [8], the symmetry classification for systems (8) is given in the finite-dimensional cases. In [16], the moving coframe method is applied in both finite-dimensional and infinite-dimensional cases. The results are gathered in the following theorem.

Theorem 3. *Every system from the class of nonlinear wave equations* (8) *is equivalent under a contact transformation to a system from one of the five invariant subclasses* $\mathcal{Q}_1$, $\mathcal{Q}_2$, $\mathcal{Q}_3$, $\mathcal{Q}_4$, *and* $\mathcal{Q}_5$*:*

$\mathcal{Q}_1$ *consists of all systems* (8) *such that* $(b/a)_x \neq 0$, $(a\,b)_u \neq 0$, *and* $b^{-1}\,(b/a)_x\,(b\,a)_u \neq \text{const}$*;*

$\mathcal{Q}_2$ *consists of all systems* $u_t = a(x,u)\,v_x$, $v_t = a(x,u)\,u_x$ *such that* $(\ln a)_{xu} \neq 0$*;*

$\mathcal{Q}_3$ *consists of all systems* $u_t = a(u)\,v_x$, $v_t = a(u)\,u_x$ *such that*

$$N_1 = a\,\left(a_u^2 a_{uu} + a a_{uu}^2 - a a_u a_{uuu}\right)\,a_u^{-4} \neq \text{const};$$

$\mathcal{Q}_4$ *consists of all systems* $u_t = a(u)\,v_x$, $v_t = a(u)\,u_x$ *such that* $N_1 = \text{const}$*;*

$\mathcal{Q}_5$ *consists of the system* $u_t = v_x$, $v_t = u_x$.

For systems from subclasses $\mathcal{Q}_1$ *and* $\mathcal{Q}_2$ *the symmetry groups are finite-dimensional, and their dimensions are between 2 and 6.*

For systems from subclasses $\mathcal{Q}_3$, $\mathcal{Q}_4$, *and* $\mathcal{Q}_5$ *the symmetry pseudo-groups are infinite-dimensional. The equations from* $\mathcal{Q}_3$ *and* $\mathcal{Q}_4$ *are linearizable by a hodograph transformation. Two equations from* $\mathcal{Q}_3$ *are equivalent under a contact transformation iff they have the same functional dependencies among the differential invariants* N_1, $N_2 = 2N_{1,u}^{-1}\left(a_{uu}a_u^{-1} - a_u a^{-1}\right) + \left(N_{1,u}^{-1}\right)_u$, *and* $N_3 = \left(4a^2 N_{1,u}^2 a_u^{-2} - 1\right) N_2 + 4N_{1,u}^{-1}\left(a^2 N_{1,u} a_u^{-2}\right)_u$.

Two systems from the subclass $\mathcal{Q}_4$ *are equivalent if and only if they have the same constant value of the invariant* N_1.

We use symmetry methods to study the model of growth of a tumour of the brain proposed by Wein and Koplow (Mathematical modeling of brain cancer to identify promising combination treatments, *Preprint, D Sloan School of Management, MIT*, 1999). The aim here is also to demonstrate the use of symmetries to obtain more complex and reliable models. We translate some of the results found into properties of the tumour of the brain.

1 Introduction

A brain tumour is a dynamic system in which cancer cells grow and spread eventually killing good cells in the brain by deprivation of space and nutrients. The tumour spreads along the periphery and often dies out in the Centre due to a lack of fuel (oxygen and nutrients from the blood). This behaviour has been compared to that of a fire [10]. To be able to destroy the tumour treatments must be able to move faster than the tumour spreads if the treatment is to destroy effectively the tumour. Tumours are known to grow extremely fast. In reference [15] the tumour growth is assumed to be uniform and we claim that an improvement to the assumption of uniformity can be made. Since there are many aspects that can be considered in this particular problem, we concentrate only on the treatment aspect of the problem.

2 Spatio-temporal model

We recall that brain-cancer cells grow very fast and, at any point in time, only a portion of them are replicating and most cancer treatments only kill cells during this active phase.

This means that, when determining the net tumour-cell kill rates, models need take this constraint into account. A small fraction of tumour cells (about one in a thousand) called clonogenic cells are capable of regrowing the entire tumour. What does this mean? If the tumour is not to grow back after treatment all these cells must be killed. A tumour such as glioblastoma multiforme has many billions of cells and no single treatment presently available is capable of such a high kill rate. Wein's paper [15] demonstrates this. For example a log cell kill rate would kill 90 % of the tumour cells. A two log treatment (such as radiation) would kill 99 % of the tumour cells etc. It is important for the treatment to have the ability to target tumour cells rather than healthy cells and to move through the brain to reach the periphery of the tumour. This does affect how well a particular treatment works. We consider the following model [15], known as the Burgess equation [1],

$$\frac{\partial n(r,t)}{\partial t} = D\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial n(r,t)}{\partial r}\right) + pn(r,t) - k_t n(r,t), \tag{1}$$

where

- $n(r,t)$ is the concentration of tumour cells at location r at time t,
- D is the diffusion coefficient (estimated at 0.0013 cm^2 per day for glioblastoma multiforme) which measures the invasiveness of the glioblastoma multiforme cells,
- p is the proliferation rate of the tumour,
- k_t is the (therapy-dependent) killing rate at time t and
- r measures the distance from the Centre (i.e. the origin of glioblastoma multiforme).

Under the rescaling $t = (p - k_t)T$, $R = (|p - k_t|D)^2 r$ we may write (1) in the parameter-free form

$$\frac{\partial n}{\partial t} = \frac{\partial^2 n}{\partial r^2} + \frac{2}{r}\frac{\partial n}{\partial r} + n, \tag{2}$$

in which we have reverted to lower case variables.

Equations (1) and (2) assume spherical symmetry. Without that assumption we have

$$\frac{\partial n}{\partial t} = \frac{\partial^2 n}{\partial r^2} + \frac{2}{r}\frac{\partial n}{\partial r} + \frac{1}{r^2}\frac{\partial^2 n}{\partial \theta^2} + \frac{1}{r^2}\cot\theta\frac{\partial n}{\partial \theta} + \frac{1}{r^2\sin^2\theta}\frac{\partial^2 n}{\partial \phi^2} + n \tag{3}$$

in which the dependent variable $n = n(t, r, \theta, \phi)$. This enables us to consider a growth of the tumour which does not possess spherical symmetry and thereby opens the possibility to deal with an initial boundary of the tumour which is not spherical. The assumption that the tumour is spherical on detection is restrictive, but it is a starting point. In this paper we accept this restriction and concentrate on treatment models of this problem and leave the extension to nonspherical symmetry to future work.

3 Lie point symmetries for the differential equation with general $K(x,t)$

Equation (2) may be written in the normal form

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + u \tag{4}$$

by the standard substitution $u(t,x) = rn(t,r)$, $x = r$. Here we consider the more general differential equation for a single cell type given by

$$\frac{\partial^2 u}{\partial x^2} - K(x,t)u - \frac{\partial u}{\partial t} = 0, \tag{5}$$

where $K(x,t)$ describes the temporal profile of the treatment and $K(x,t)u$ is the rate of removal of the tumour cells. In the model in reference [15] the treatment is allowed to be only a function of the time and we modify this to make it a function of both the position of the of the cancerous cells and time. This is a more realistic assumption.

The analysis of (5) for its Lie point symmetries has been established for a long time [4] (see also [5] and [13]). No matter the structure of $K(x,t)$ and there are always the homogeneity and solution symmetries, *videlicet*

$$\Gamma_h = u\partial_u \qquad \text{and} \qquad \Gamma_s = f(t,x)\partial_u, \tag{6}$$

where $f(t,x)$ and is any solution of (5). There are four possibilities for the structure of $K(x,t)$.

- Case I: $K(x,t)$ is an undifferentiated function. There is no symmetry additional to the two generic symmetries in (6).
- Case II: $K(x,t) = K(x)$. There is the additional symmetry

$$\Gamma_1 = \partial_t \tag{7}$$

which reflects the invariant of (5) under time translation. Since $[\Gamma_1, \Gamma_h]_{LB} = 0$, the Lie algebra of the finite symmetries is $2A_1$ Mubarakzyanov classification scheme [6–9].

- Case III: $K(x,t) = N\left(Ax+B\right)^2 + C + M/\left(Ax+B\right)^2$, where A, B, C, M and N are arbitrary constants and M and A are nonzero. This case can be reduced to the equivalence class

$$K_E(x) = \frac{\mu}{x^2} \tag{8}$$

by means of a suitable transformation [12]. With K as in (8) the additional symmetries are

$$\Gamma_1 = \partial_t, \qquad \Gamma_2 = 2t\partial_t + x\partial_x, \qquad \Gamma_3 = 4t^2\partial_t + 4tx\partial_x - \left(x^2 - 2t\right)u\partial_u \tag{9}$$

which have the Lie brackets $[\Gamma_1, \Gamma_2] = 2\Gamma_1$, $[\Gamma_2, \Gamma_3] = 2\Gamma_3$ and $[\Gamma_3, \Gamma_1] = -4\Gamma_2$ which is a representation of $sl(2,\mathbb{R})$. Since $[\Gamma_i, \Gamma_h] = 0$, $i = 0, 3$, the algebra of the finite symmetries is $sl(2,\mathbb{R}) \oplus A_1$.

- Case IV: $K(x) = Ax^2 + Bx + C$, where again A, B and C are arbitrary constants. This case can be reduced to the equivalence class

$$K_E = 0 \tag{10}$$

by the same transformation as used in Case III. The additional Lie point symmetries are those in (9) plus

$$\Gamma_4 = \partial_x, \qquad \Gamma_5 = 2t\partial_x - xu\partial_u \tag{11}$$

which have the Lie brackets $[\Gamma_4, \Gamma_5] = -\Gamma_4$. Consequently one needs to introduce Γ_h to close the algebra. Since $[\Gamma_4, \Gamma_h] = 0$ and $[\Gamma_5, \Gamma_h] = 0$, the algebra is $A_{3,1}$, commonly known as the Weyl algebra.

We note that the existence of the exceptional symmetries, Γ_1, $\Gamma_{2\pm}$ and $\Gamma_{3\pm}$, is directly related to the existence of Noether symmetries [11] for a Lagrangian of the form $\frac{1}{2}\left(\dot{x}^2 + 4K\right)$ [3].

Each of these cases, although Case I is trivial, is the representative of an equivalence class under point transformation. The essential point is that the number of Lie point symmetries additional to the generic symmetries, Γ_h and Γ_s, is limited to 0, 1, 3 or 5 for an equation of the form (5). To construct solutions using the symmetries viable forms of $K(x,t)$ are those for which the number of Lie point symmetries is 3 or 5, then we can use the method of construction employed by Lemmer *et al* [3] in the case of the time-dependent Schrödinger equation.

4 Similarity solutions of the Burgess equation

In the original model [15] equation (5) has the form

$$\frac{\partial u}{\partial t} - \frac{\partial^2 u}{\partial x^2} - (p - k_t)u = 0, \tag{12}$$

where we recall that the constants p and k_t representative proliferation rate and the killing rate respectively. Equation (12) is of Class IV and has the nontrivial Lie point symmetries

$$\begin{aligned}
&\Gamma_1 = \partial_t, \qquad \Gamma_2 = 2t\partial_t + x\partial_x + 2(p-k_t)tu\partial_u,\\
&\Gamma_3 = 4t^2\partial_t + 4tx\partial_x + \left[4(p-k_t)t^2 - 2t - x^2\right]u\partial_u,\\
&\Gamma_4 = \partial_x, \qquad \Gamma_5 = 2t\partial_x - xu\partial_u,
\end{aligned} \tag{13}$$

where we note the differences in Γ_2 and Γ_3 due to the presence of the term $(p-k_t)u$ (12). Any of these symmetries apart from Γ_1 are suitable symmetries for the construction of similarities solutions and, guided by the example of Lemmer *et al* [3] in a treatment of the time-dependent Schrödinger equation, we choose Γ_4. The invariants of Γ_4 are found from the solution of the associated Lagrange's system

$$\frac{\mathrm{d}t}{0} = \frac{\mathrm{d}x}{1} = \frac{\mathrm{d}u}{0} \tag{14}$$

and are

$$v = t \qquad \text{and} \qquad w = u \tag{15}$$

so that we may set

$$u = f(t) \tag{16}$$

and substitute it into (12) to obtain

$$f(t) = \exp\left[(p-k_t)\,t\right], \tag{17}$$

where we omit the multiplicitive constant of integration. Hence

$$u_0 = \exp\left[(p-k_t)\,t\right], \tag{18}$$

where we use the subscript zero to denote the basic solution. We use the property that symmetries map solutions into solutions and apply Γ_5 to the solution surface for u_0, *videlicet*

$$\Sigma_0 = u^{-1}\exp\left[(p-k_t)\,t\right] \tag{19}$$

to obtain

$$u_1 = x\exp\left[(p-k_t)\,t\right]. \tag{20}$$

Similarly we obtain

$$u_2 = \left(2t + x^2\right)\exp\left[(p-k_t)\,t\right], \qquad u_3 = \left(6tx + x^3\right)\exp\left[(p-k_t)\,t\right], \qquad \ldots. \tag{21}$$

Equally we could commence with Γ_5 to obtain a basic solution and use Γ_4 to create further solutions from the solution surface. We find that

$$\begin{aligned}
&v_0 = t^{-1/2}\exp\left[(p-k_t)\,t - \frac{x^2}{4t}\right], \qquad v_1 = -\frac{x}{2t^{3/2}}\exp\left[(p-k_t)\,t - \frac{x^2}{4t}\right],\\
&v_2 = t^{-1/2}\left(\frac{x^2}{4t^2} - \frac{1}{2t}\right)\exp\left[(p-k_t)\,t - \frac{x^2}{4t}\right], \qquad \ldots.
\end{aligned} \tag{22}$$

We note that we can use Γ_2 and Γ_3 to generate solutions in the same way and that they also act as ladder operators on the solutions obtained by the other symmetries.

We recall that intensity of cells is essentially given by $n = u/x$ so that the number of cells within a sphere of radius X is

$$N_X = 4\pi \int_0^X x^2 \mathrm{d}x\, n(x,t) = 4\pi \int_0^X xu(x,t)\,\mathrm{d}x. \tag{23}$$

A feature of the solutions is the critical nature of the value of the expression $p - k_t$. If $p - k_t > 0$, the number of cells increases exponentially with time which is one of the salient properties of glioblastoma multiforme and the reason for its generally fatal outcome. By the time the tumour is large enough to be detected the number of cells is proliferating at a prodigious rate.

In the case that $p - k_t < 0$ the solutions indicate a rapid drop in the number of cells. However, the assumption of a constant killing rate is not a good one. In the case of chemotherapy the efficacy of the chemical decreases with time, usually in an exponential fashion. Thus we should replace k_t with something like $k\exp[-\sigma t]$. The number of nontrivial symmetries is unchanged. They are

$$\begin{aligned}
&\Lambda_1 = \partial_t + ku\exp\left[-\sigma t\right]\partial_u, \qquad \Lambda_2 = 2t\partial_t + x\partial_x + 2t\left[p - k\exp\left[-\sigma t\right]\right]u\partial_u,\\
&\Lambda_3 = 4t^2\partial_t + 4tx\partial_x - \left[2t + x^2 - 4t^2\left(p - k\exp\left[-\sigma t\right]\right)\right]u\partial_u,\\
&\Lambda_4 = \partial_x, \qquad \Lambda_5 = 2t\partial_x - xu\partial_u.
\end{aligned} \tag{24}$$

In the same fashion as above we obtain the two families of solutions

$$\begin{aligned}
&u_0 = \exp\left[pt + \frac{k}{\sigma}\,\mathrm{e}^{-\sigma t}\right], \qquad u_1 = x\exp\left[pt + \frac{k}{\sigma}\,\mathrm{e}^{-\sigma t}\right]\\
&u_2 = \left(2t + x^2\right)\exp\left[pt + \frac{k}{\sigma}\,\mathrm{e}^{-\sigma t}\right], \qquad \ldots,\\
&v_0 = t^{-1/2}\exp\left[pt + \frac{k}{\sigma}\,\mathrm{e}^{-\sigma t} - \frac{x^2}{4t}\right], \qquad v_1 = -\frac{x}{2t^{3/2}}\exp\left[pt + \frac{k}{\sigma}\,\mathrm{e}^{-\sigma t} - \frac{x^2}{4t}\right],\\
&v_2 = t^{-1/2}\left(\frac{x^2}{4t^2} - \frac{1}{2t}\right)\exp\left[pt + \frac{k}{\sigma}\,\mathrm{e}^{-\sigma t} - \frac{x^2}{4t}\right], \qquad \ldots.
\end{aligned}$$

in which we note the first similarity to the solutions listed in (21) and (22) and from which we see that the concentration of the tumor cells increases with time for both series of solutions and eventually decreases with radial distance in the second series. The assumption of a constant kill rate in space is suspect since the inner cells are more crowded and the supply of nutrients is not as great as on the surface of the tumour. From our discussion of the symmetries available for different $K(x,t)$ we can see that there are several possibilities which maintain a rich supply of Lie point symmetries. For example, we take $K(x,t) = px - k$, with both p and k constant for simplicity although they both could be time-dependent. Equation (12) now has the five nontrivial Lie point symmetries

$$\begin{aligned}
&\Delta_1 = \partial_t, \qquad \Delta_2 = 2t\partial_t + \left(x - 3pt^2\right)\partial_x + t\left(3px - 2k - p^2t^2\right)u\partial_u,\\
&\Delta_3 = 4t^2\partial_t + 4t\left(x - pt^2\right)\partial_x - \left(4kt^2 + x^2 + 2t - 6pt^2x\right)u\partial_u,\\
&\Delta_4 = \partial_x + ptu\partial_u, \qquad \Delta_5 = 2t\partial_x + \left(pt^2 - x\right)u\partial_u
\end{aligned} \tag{25}$$

and from Δ_4 and Δ_5 we obtain, in the manner described above, the solutions

$$\begin{aligned}
&u_0 = \exp\left[ptx + \frac{1}{3}p^2t^3 - kt\right], \qquad u_1 = \left(x + pt^2\right)\exp\left[ptx + \frac{1}{3}p^2t^3 - kt\right],\\
&u_2 = \left[2t + \left(x + pt^2\right)^2\right]\exp\left[ptx + \frac{1}{3}p^2t^3 - kt\right], \qquad \ldots,
\end{aligned}$$

$$
\begin{aligned}
v_0 &= t^{-1/2}\exp\left[\frac{1}{2}ptx - kt - \frac{1}{12}p^2t^3 - \frac{x^2}{4t}\right],\\
v_1 &= -\frac{1}{2}t^{-1/2}\left(pt + \frac{x}{t}\right)\exp\left[\frac{1}{2}ptx - kt - \frac{1}{12}p^2t^3 - \frac{x^2}{4t}\right],\\
v_2 &= \frac{1}{4}t^{-1/2}\left[\left(pt + \frac{x}{t}\right)^2 - \frac{2}{t}\right]\exp\left[\frac{1}{2}ptx - kt - \frac{1}{12}p^2t^3 - \frac{x^2}{4t}\right], \qquad \ldots
\end{aligned} \tag{26}
$$

from which we can infer the first set of solutions increases with no bound for both t and x and the second series of solutions tends to zero for large t and x.

5 Conclusion

We conclude that the therapy-dependent killing rate K need not be a function of time only but of both position and time. This is an improvement to the model of Wein & Koplow [15]. The symmetry analysis of the model yields some interesting properties, i.e., the symmetries are ladder operators and can be used to map solutions into solutions of the model. Several aspects of the problem remain unanswered from a mathematical point of view and, as additional therapies are developed, definitions of parameters in the model will be helpful in planning the dose and timing of these therapies which are currently limited by the tolerance of normal brain for XRay-irradiation and hematopeotic tissues for chemotherapies. In addition to this one may ask how much the diffusion constant D varies from one glioma to another and how the cell concentration or cell type contributes independently to D. In his book on Mathematical Biology Murray [10] remarks that the prediction of tumour response to therapy is a goal which mathematical models could help to reach.

In the treatment of HIV-AIDS the use of recombinant viruses has been proposed [14] and numerical simulations suggest that such viruses are very effective in reducing the viral load of the HIV and reasonably effective in restoring the number of healthy cells. Effectively the recombinant virus controls the evolution of the disease although it does not provide a cure. In the case of a tumour such as glioblastoma multiforme the development of a viral therapy could remedy the problem of exponential decay of the therapeutic agent. Now there are two coupled equations, one for the growth of the number of cancer cells and one for the growth of the number of viruses. A model for such a system is a generalisation of the Burgess equation (1) such as

$$
\begin{aligned}
\frac{\partial n_1}{\partial t} &= D_1\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial n_1}{\partial r}\right) + (p_1 - k_2n_2)\,n_1,\\
\frac{\partial n_2}{\partial t} &= D_2\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial n_2}{\partial r}\right) + (p_2 - k_1n_1)\,n_2
\end{aligned} \tag{27}
$$

in which n_1 and n_2 represent the densities of the tumour cells and viruses, p_1 and p_2 their proliferation rates and k_1 and k_2 the killing rates for cells/virus. Such models are to be the subject of further investigation.

Using results of A. Gonzalez-Lopez, N. Kamran and P.J. Olver we describe differential invariants and operators of invariant differentiation of transformation groups acting on the real plane.

1 Introduction

Differential invariants emerged as one of the most important tools in investigation of differential equations in the works by S. Lie. In 1884 [3] he proved that any non-singular invariant system of differential equations can be expressed in terms of differential invariants of the corresponding symmetry group. In this paper he also applied differential invariants to integration of ODEs. Differential invariants for all finite-dimensional local transformation groups on a space of two complex variables was described also by S. Lie [4]. A modern treatment of these results was adduced in [6], namely for all non-equivalent realizations of Lie algebras of transformation groups on the complex plane functional bases of differential invariants, operators of invariant differentiation and Lie determinants were constructed. Basic concepts of the theory of differential invariants and review of main results may be found in [7, 8].

In this paper for every realization of Lie algebras of transformation groups acting on the real plane from [2] we construct a functional basis of differential invariants and operators of invariant differentiation. For this purpose we find transformations over complex field that reduce realizations from [2] to realizations from [6]. Such nontrivial transformations are adduced in Table 1 (numbers N_1 and N_2 correspond to numeration of real and complex realizations in [2,6]). Using these transformations and results of [6] we completely describe differential invariants of transformation groups on the real plane. This description is presented in the form of Table 2.

Table 1. Transformations of compleficated real realizations to complex ones.

N_1	Transformations of space variables	Transformations of basis elements	N_2
1	$\tilde{x}=x-iy$, $\tilde{y}=x+iy$	$\tilde{e}_1=\frac{1+i}{2}(e_1+e_2)$, $\tilde{e}_2=\frac{1}{c+i}e_3$, $\tilde{e}_3=\frac{1-i}{2}(e_1-e_2)$	2.7, $k=1$
2	$\tilde{x}=x-iy$, $\tilde{y}=\frac{1}{2iy}$	$\tilde{e}_1=e_1$, $\tilde{e}_2=e_2$, $\tilde{e}_3=e_3$	2.2
3	$\tilde{x}=-\frac{1}{ix+y}$, $\tilde{y}=\frac{ix+y}{1+x^2+y^2}$	$\tilde{e}_1=\frac{1}{2}(ie_2+e_3)$, $\tilde{e}_2=ie_1$, $\tilde{e}_3=\frac{1}{2}(e_3-ie_2)$	2.2
4	$\tilde{x}=\frac{y-ix}{2}$, $\tilde{y}=-\frac{y+ix}{2}$	$\tilde{e}_1=ie_1-e_2$, $\tilde{e}_2=ie_1+e_2$, $\tilde{e}_3=\frac{e_3+ie_4}{2}$, $\tilde{e}_4=\frac{e_3-ie_4}{2}$	2.9, $k=1$
7	$\tilde{x}=y+ix$, $\tilde{y}=y-ix$	$\tilde{e}_1=\frac{e_1+ie_2}{2i}$, $\tilde{e}_2=\frac{e_3-ie_4}{2}$, $\tilde{e}_3=\frac{e_6+ie_5}{2}$, $\tilde{e}_4=\frac{ie_2-e_1}{2i}$, $\tilde{e}_5=\frac{e_3+ie_4}{2}$, $\tilde{e}_6=\frac{e_6-ie_5}{2}$	2.4
17	$\tilde{x}=y$, $\tilde{y}=\frac{1}{x-y}$	$\tilde{e}_1=e_1$, $\tilde{e}_2=e_2$, $\tilde{e}_3=e_3$	2.2
18	$\tilde{x}=x$, $\tilde{y}=\frac{1}{y^2}$	$\tilde{e}_1=e_1$, $\tilde{e}_2=\frac{1}{2}e_2$, $\tilde{e}_3=e_3$	2.1
19	$\tilde{x}=x$, $\tilde{y}=\frac{1}{y}$	$\tilde{e}_1=e_1$, $\tilde{e}_2=e_2$, $\tilde{e}_3=-e_3$, $\tilde{e}_4=e_4$	2.3

Table 2. Differential invariants of transformation groups on the real plane.

N	Realization	Fundamental differential invariants	Operator of invariant differentiation
1	$\partial_x,\ \partial_y,\ (cx+y)\partial_x+(cy-x)\partial_y,\ 0\le c$	$\frac{y''e^{-c\arctan y'}}{P^{3/2}}$	$\frac{e^{-c\arctan y'}}{\sqrt{P}}D_x$
2	$\partial_x,\ x\partial_x+y\partial_y,\ (x^2-y^2)\partial_x+2yx\partial_y$	$\frac{y''y+(y')^2+1}{P^{3/2}}$	$\frac{2y}{\sqrt{P}}D_x$
3	$y\partial_x-x\partial_y,\ (1+x^2-y^2)\partial_x+2xy\partial_y,$ $2xy\partial_x+(1+y^2-x^2)\partial_y$	$\frac{y''(1+x^2+y^2)}{P^{3/2}}+\frac{2(y-xy')}{\sqrt{P}}$	$\frac{1+x^2+y^2}{\sqrt{P}}D_x$
4	$\partial_x,\ \partial_y,\ x\partial_x+y\partial_y,\ y\partial_x-x\partial_y$	$\frac{y'''P}{(y'')^2}-3y'$	$\frac{P}{y''}D_x$
5	$\partial_x,\ \partial_y,\ x\partial_x-y\partial_y,\ y\partial_x,\ x\partial_y$	$\frac{3y''y^{\rm IV}-5(y''')^2}{(y'')^{8/3}}$	$\frac{1}{(y'')^{1/3}}D_x$
6	$\partial_x,\ \partial_y,\ x\partial_x,\ y\partial_y,\ y\partial_x,\ x\partial_y$	$\frac{S_5}{R_4^{3/2}}$	$\frac{y''}{\sqrt{R_4}}D_x$
7	$\partial_x,\ \partial_y,\ x\partial_x+y\partial_y,\ y\partial_x-x\partial_y,$ $(x^2-y^2)\partial_x-2xy\partial_y,\ 2xy\partial_x-(y^2-x^2)\partial_y$	$\frac{U}{Q^3}$	$\frac{P}{\sqrt{Q}}D_x$
8	$\partial_x,\ \partial_y,\ x\partial_x,\ y\partial_y,\ y\partial_x,\ x\partial_y,$ $x^2\partial_x+xy\partial_y,\ xy\partial_x+y^2\partial_y$	$\frac{V_7}{S_5^{8/3}}$	$\frac{y''}{S_5^{1/3}}D_x$
9	∂_x	$F(y)$	D_x
10	$\partial_x,\ x\partial_x$	$F(y),\ \frac{(y')^k}{y^{(k)}}$	D_x^2
11	$\partial_y,\ y\partial_y,\ y^2\partial_y$	$\frac{Q_3}{(y')^2}$	D_x
12	$\partial_x,\ \partial_y,\ x\partial_x+cy\partial_y,\ 0<\lvert c\rvert\le 1$	$c=1,\quad \frac{y'''}{(y'')^2}$ $c\ne 1,\quad y''y'^{\frac{2-c}{c-1}}$	$\frac{1}{y''}D_x$ $(y')^{\frac{1}{c-1}}D_x$
13	$\partial_x,\ \partial_y,\ x\partial_x,\ y\partial_y$	$\frac{y'y'''}{(y'')^2}$	$\frac{y'}{y''}D_x$
14	$\partial_x,\ \partial_y,\ x\partial_x,\ x^2\partial_x$	$\frac{Q_3}{(y')^4}$	$\frac{1}{y'}D_x$
15	$\partial_x,\ \partial_y,\ x\partial_x,\ y\partial_y,\ x^2\partial_x$	$\frac{S_4}{Q_3^{\frac{3}{2}}}$	$\frac{y'}{\sqrt{Q_3}}D_x$
16	$\partial_x,\ \partial_y,\ x\partial_x,\ y\partial_y,\ x^2\partial_x,\ y^2\partial_y$	$\frac{U_5}{Q_3^3}$	$\frac{y'}{\sqrt{Q_3}}$
17	$\partial_x+\partial_y,\ x\partial_x+y\partial_y,\ x^2\partial_x+y^2\partial_y$	$\frac{2y'(1+y')+y''(x-y)}{(y')^{3/2}}$	$\frac{x-y}{\sqrt{y'}}D_x$
18	$\partial_x,\ 2x\partial_x+y\partial_y,\ x^2\partial_x+xy\partial_y$	y^3y''	y^2D_x
19	$\partial_x,\ x\partial_x,\ y\partial_y,\ x^2\partial_x+xy\partial_y$	$\frac{3y'y''+yy'''}{\sqrt{y}(y'')^{3/2}}$	$\sqrt{\frac{y}{y''}}D_x$
20	$\partial_y,\ \xi_1(x)\partial_y,\ \dots,\ \xi_r(x)\partial_y,\ 1\le r$	$x,\ \frac{W(y,1,\xi_1,\dots,\xi_r)}{W(1,\xi_1,\dots,\xi_r)}$	D_x
21	$\partial_y,\ y\partial_y,\ \xi_1(x)\partial_y,\ \dots,\ \xi_r(x)\partial_y,\ 1\le r$	$D_x\ln W(y,\xi_1,\dots,\xi_r)$	D_x
22	$\partial_x,\ \eta_1(x)\partial_y,\ \dots,\ \eta_r(x)\partial_y,\ 1\le r$	$\frac{W(y,\eta_1,\dots,\eta_r)}{W(\eta_1,\dots,\eta_r)}$	D_x
23	$\partial_x,\ y\partial_y,\ \eta_1(x)\partial_y,\ \dots,\ \eta_r(x)\partial_y,\ r\ge 1$	$D_x\ln W(y,\eta_1,\dots,\eta_r)$	D_x
24	$\partial_x,\ \partial_y,\ x\partial_x+cy\partial_y,$ $x\partial_y,\dots,x^r\partial_y,\ r\ge 1$	$c\ne r+1,\ (y^{(r+1)})^{\frac{2-c+r}{c-(r+1)}}y^{(r+2)}$ $c=r+1,\ y^{(r+1)},\ \frac{y^{(r+3)}}{(y^{(r+2)})^2}$	$(y^{(r+1)})^{\frac{1}{c-(r+1)}}D_x$ $\frac{1}{y^{(r+2)}}D_x$
25	$\partial_x,\ \partial_y,\ x\partial_y,\ \dots,\ x^{r-1}\partial_y,$ $x\partial_x+(ry+x^r)\partial_y,\ r\ge 1$	$y^{(r+1)}e^{\frac{y^{(r)}}{r!}}$	$e^{\frac{y^{(r)}}{r!}}D_x$
26	$\partial_x,\ \partial_y,\ x\partial_x,\ x\partial_y,\ y\partial_y,$ $x^2\partial_y,\ \dots,\ x^r\partial_y,\ r\ge 1$	$\frac{y^{(r+1)}y^{(r+3)}}{(y^{(r+2)})^2}$	$\frac{y^{(r+1)}}{y^{(r+2)}}D_x$
27	$\partial_x,\ \partial_y,\ 2x\partial_x+ry\partial_y,\ x\partial_y,$ $x^2\partial_x+rxy\partial_y,\ x^2\partial_y,\ \dots,\ x^r\partial_y,\ r\ge 1$	$\frac{Q_{r+3}}{(y^{(r+1)})^{\frac{2(r+4)}{r+2}}}$	$\frac{1}{(y^{(r+1)})^{\frac{2}{r+2}}}D_x$
28	$\partial_x,\ \partial_y,\ x\partial_x,\ x\partial_y,\ y\partial_y,$ $x^2\partial_x+rxy\partial_y,\ x^2\partial_y,\ \dots,\ x^r\partial_y,\ r\ge 1$	$\frac{S_{r+4}}{Q_{r+3}^{3/2}}$	$\frac{y^{(r+1)}}{\sqrt{Q_{r+3}}}D_x$

In Table 2 $W(f_1,\dots,f_k)$ denotes the Wronskian of the functions $f_1(x)$, $\dots$, $f_k(x)$, D_x is the operator of total differentiation. We also use the following notations:

$$S_{k+3}=(k+1)^2\big(y^{(k)}\big)^2y^{(k+3)}-3(k+1)(k+3)y^{(k)}y^{(k+1)}y^{(k+2)}+2(k+2)(k+3)\big(y^{(k+1)}\big)^3,$$
$$Q_{k+2}=(k+1)y^{(k)}y^{(k+2)}-(k+2)\big(y^{(k+1)}\big)^2,\qquad R_4=3y''y^{\mathrm{IV}}-5(y''')^2,$$
$$P=1+(y')^2,\qquad Q=y'''P-3y'(y'')^2,$$
$$U=4y^{\mathrm{V}}P^3Q+10y^{\mathrm{IV}}y''P^3\left(4y'''y'+3(y'')^2\right)-5(y^{\mathrm{IV}})^2P^4+40(y''')^2(y'')^2\left((y')^2-2\right)P^2$$
$$-40(y''')^3y'P^3-180y'''y'(y'')^4\left((y')^2-1\right)P^2-(y'')^6\left(45(6(y')^2+1)-135(y')^4\right),$$
$$U_5=(y')^2\left(Q_3D_x^2Q_3-\frac{5}{4}(D_xQ_3)^2\right)+y'y''Q_3D_xQ_3-\left(2y'y'''-(y'')^2\right)Q_3^2,$$
$$V_7=(y'')^2\left(S_5D_x^2S_5-\frac{7}{6}(D_xS_5)^2\right)+y''y'''S_5D_xS_5-\frac{1}{2}\left(9y''y^{\mathrm{IV}}-7(y''')^2\right)S_5^2.$$

The presented results may be used for group classification of ODEs of any finite order. So, in the near future we plan to review and to generalize results of group classification of third and fourth ODEs that were obtained in [1, 10]. To investigate differential invariants of transformations groups acting in the spaces of more than two variables in similar way we can use classification of realizations of real low-dimensional Lie algebras that was obtained in [9].

Acknowledgements

On Symmetry Group Properties of the Benney Equations

Teoman ÖZER

Istanbul Technical University, Faculty of Civil Engineering, Division of Mechanics, 34469 Maslak, Istanbul, Turkey
E-mail: *tozer@itu.edu.tr*

In the present study, we investigate the symmetry groups of Benney equations that are the system of nonlinear integro-differential equations. We first investigate the symmetry groups of the Benney equations by using the method. Then we obtain all reduced forms of the system of integro-differential equations with fewer variables based on symmetry groups; and lastly, we seek a similarity solution to the reduced system of the equations.

1 Introduction

Symmetry group analysis deals with applications of continuous symmetry groups to the system of differential equations in engineering, mathematics, and physics. However, in the case of integro-differential equations (IDE), there is no general method of investigating the Lie symmetry groups of these equations based on the solution of their determining equations. The main difficulty in applying Lie's infinitesimal techniques to these systems is their nonlocality, and the approach used in the classical group theory cannot be applied for the investigation of symmetry groups of IDE.

There are some studies about symmetry groups of integro-differential equations in the literature. Meleshko [1] searches the Lie point symmetries of the one-dimensional visco-elastic equation and gets a classification with respect to the free term and the kernel function. The method is based on the fact that one considers the determining equations on any solution at any point and any time, for example, at initial time t_0. Here, it is very important to have an existence of solution of the Cauchy problem, which allows splitting the determining equations. It is worth to note that the same problem stays in an application of the group analysis to differential equations. For differential equations the Cauchy–Kovalewskaya theorem treats this. One-dimensional nonlocal elasticity and one dimensional visco-elasticity equations seem a similar structure due the type of their integral equations, it is clear that these equations have different characteristics with respect to the mathematical and kinematics aspects. First, one-dimensional nonlocal elasticity is in the form of Fredholm integro-differential equations by Özer [2] and one dimensional visco-elasticity equation is in the form of Volterra integro-differential equation [1]. In addition, these two equations describe two different mechanics behaviors of the solids. It is important to define symmetry group properties of nonlocal elasticity equations in order to understand these different characteristics of the equations based on their symmetry groups. In addition, Özer [3] investigated symmetry group properties of two-dimensional elastodynamics problem of nonlocal continuum mechanics and obtained a classification due to the kernel function and the free term.

Bobylev [4] is another author who studied the symmetry groups of the integro-differential equations. He obtained all symmetry groups of the Boltzmann and examined some invariant solutions of the Boltzmann equation using its Lie point symmetries. This approach in this study is based on the assumption that we restrict the determining equations to the subset of the solution of integro-differential equation determined by the initial conditions. Firstly, the coefficients of the infinitesimal operator are assumed to be locally analytic functions, and then

these coefficients are represented by Taylor series with respect to the independent variable of the equation. The determining equation is decomposed with respect to the different powers of an arbitrary parameter that exists in the initial functions. Finally the determining equations are split to the series of equations by equating the coefficient of every different power of the independent parameter to zero. Symmetry groups are found by the so-obtained equations.

Chetverikov and Kudryavtsev [5] have written an important article on the subject. The method in their study consists in reducing an integro-differential equation to a system of boundary differential equation and in computing symmetries and conservation laws for the system of integro-differential equations. In the study symmetry is considered as a geometric concept. Therefore, in order to define the symmetry of something it is first represented by some geometric model. Then the symmetry is found by considering the transformations of the model. In the case of integro-differential equations, the analogy with differential equations can also be used. In the method the first step is the introduction of the nonlocal variables. In the second step the initial system is transformed to the functional differential equations. Later the generalized jet spaces are defined so that boundary differential equations can be expanded as submanifolds of these spaces. Finally, a geometric theory of boundary differential equations is constructed similar to the geometry of nonlinear differential equations. This method is fundamentally different from our method that we use in the study.

The last work to be mentioned here is done by Taranov [6]. The first step in this approach is to find the symmetries of the equation dependent on finite number of variables. The symmetries of the system of integro-differential equations are obtained by approaching the number of variables to infinity.

2 Symmetry groups of the Benney equations

In this part, we present briefly the general characteristics of the method of investigating the symmetry groups of the Benney equations introduced in the study [7]. The method presents an important opportunity for investigation of symmetry groups and similarity solutions, as well as solutions of some boundary value problems related to other problems, including IDE in engineering and science. We consider a scalar kth-order IDE represented by

$$\prod(x,u,\underset{1}{u},\ldots,\underset{k}{u})+\int dx\hat{\prod}(x,u,\underset{1}{u},\ldots,\underset{k}{u})=0. \tag{1}$$

Then, the infinitesimal transformation which is the invariance criterion of invariance of an integro-differential equation introduced in [8, 9] is written as

$$\underset{k}{X}\prod(x,u,\underset{1}{u},\ldots,\underset{k}{u})+\int dx\left[\underset{k}{X}\hat{\prod}(x,u,\underset{1}{u},\ldots,\underset{k}{u})+\hat{\prod}\sum_i\partial_i\xi_i\right]=0. \tag{2}$$

Roberts [8] and Zawistowski [9] studied the symmetry group properties of the one-dimensional Vlasov–Maxwell equation based on the infinitesimal criterion (2) of integro-differential equations.

Here, we investigate the symmetry groups of the system of integro-differential equations corresponding to the Benney kinetic equations below:

$$\frac{\partial f(x,t,v)}{\partial t}+v\frac{\partial f(x,t,v)}{\partial x}-\frac{\partial f(x,t,v)}{\partial v}\frac{\partial A_0(x,t)}{\partial x}=0,\qquad A_0(x,t)=\int_{-\infty}^{\infty}f(x,v,t)dv, \tag{3}$$

where x and t are the independent variables as spatial coordinate and time, respectively, f is the distribution function, v is the horizontal component of the flow velocity, and A_0 is the function defined as

$$\frac{\partial A_n}{\partial t}+\frac{\partial A_{n+1}}{\partial x}+nA_{n-1}\frac{\partial A_0}{\partial x}=0, \tag{4}$$

where

$$A_n = \int_0^h u^n(x,y,t)dy, \qquad n = 0,1,2,\ldots. \tag{5}$$

For this purpose, we can define the infinitesimal operator for the problem (3) with respect to the definition of the infinitesimal operator for a partial differential equation as

$$X = \xi^x\partial_x + \xi^t\partial_t + \xi^v\partial_v + \eta^f\partial_f + \eta^{A_0}\partial_{A_0}. \tag{6}$$

Here x, v, t are independent variables and f, A_0 are dependent variables of the problem. After the calculations, we obtain a five-parameter Lie group for the Benney equations based on the condition (2) as shown below:

$$\begin{aligned} &\eta^{A_0} = 2a_1A_0, \qquad \eta^f = a_1f, \qquad \xi^v = a_1v + a_3,\\ &\xi^x = (2a_1 - a_4)x + a_3t + a_5, \qquad \xi^t = (a_1 - a_4)t + a_2, \end{aligned} \tag{7}$$

that are equivalent results obtained by Krasnoslobodtsev [10] and Ibragimov [11], where a_1, a_2, a_3, a_4 and a_5 are constants.

3 Reduced forms of the Benney equations

In this part, we present all reduced forms of the Benney equations by using the corresponding symmetry groups. First, we construct the characteristic equations with respect to the expressions (7) as below:

$$\begin{aligned} &\frac{dx}{(2a_1 - a_4)x + a_3t + a_5} = \frac{dt}{(a_1 - a_4)t + a_2} = \frac{dv}{a_1v + a_3} = \frac{df}{a_1f},\\ &\frac{dx}{(2a_1 - a_4)x + a_3t + a_5} = \frac{dt}{(a_1 - a_4)t + a_2} = \frac{dv}{a_1v + a_3} = \frac{dA_0}{2a_1A_0}. \end{aligned} \tag{8}$$

We obtain the general similarity variables and reduced forms of the Benney equations by using the "integrating factor" technique. Then if we substitute the similarity forms to the original equation (3) by using new similarity variables, then we get the new system of IDE with two new similarity variables, namely ξ_1 and ξ_2, as independent variables; and $\tilde{f}$ and $\tilde{A}_0$ as dependent variables.

If we take the conditions as $a_1 \neq 0$, $a_4 \neq 2a_1$, $a_4 \neq a_1$, then we obtain the general reduced form of equation (3) as

$$\begin{aligned} &(-2a_1 + a_4)\xi_1\frac{\partial\tilde{f}(\xi_1,\xi_2)}{\partial\xi_1} - a_1\tilde{f}(\xi_1,\xi_2) + a_1\xi_2\frac{\partial\tilde{f}(\xi_1,\xi_2)}{\partial\xi_2}\\ &\quad + \xi_2\frac{\partial\tilde{f}(\xi_1,\xi_2)}{\partial\xi_1} - \frac{d\tilde{A}_0(\xi_1)}{d\xi_1}\frac{\partial\tilde{f}(\xi_1,\xi_2)}{\partial\xi_2} = 0, \qquad \tilde{A}_0 = \int_{-\infty}^{\infty}\tilde{f}(\xi_1,\xi_2)d\xi_2, \end{aligned} \tag{9}$$

where the first and the second similarity variables and similarity forms are as follows:

$$\begin{aligned} \xi_1 &= x[(a_1 - a_4)t + a_2]^{(-2a_1+a_4)(a_1-a_4)^{-1}}\\ &\quad - \frac{a_3}{a_1}\left[-\frac{a_1a_5 + a_2a_3}{(a_3(2a_1 - a_4)} - t\right][(a_1 - a_4)t + a_2]^{(-2a_1+a_4)(a_1-a_4)^{-1}},\\ \xi_2 &= v[(a_1 - a_4)t + a_2]^{-a_1(a_1-a_4)^{-1}} + \frac{a_3}{a_1}[(a_1 - a_4)t + a_2](-a_1)(a_1 - a_4)^{-1},\\ f(x,v,t) &= [(a_1 - a_4)t + a_2]^{a_1(a_1-a_4)^{-1}}\tilde{f}(\xi_1,\xi_2),\\ A_0(x,t) &= [(a_1 - a_4)t + a_2]^{2a_1(a_1-a_4)^{-1}}\tilde{A}_0(\xi_1). \end{aligned} \tag{10}$$

4 The relations between Benney equations and shallow-water equations and similarity solutions

It may possible to transform the solutions of Benney equations into solutions of nonlinear-shallow water equations

$$\frac{\partial h(x,t)}{\partial t} + u(x,t)\frac{\partial h(x,t)}{\partial x} + h(x,t)\frac{\partial u(x,t)}{\partial x} = 0,$$
$$\frac{\partial u(x,t)}{\partial t} + u(x,t)\frac{\partial u(x,t)}{\partial x} + \frac{\partial h(x,t)}{\partial x} = 0. \tag{11}$$

by using the following expression given by Gibbons [12]:

$$f(x,t,v) = h(x,t)\delta(u(x,t) - v), \tag{12}$$

where $h(x,t)$ and $u(x,t)$ are solutions of the nonlinear shallow-water equations (11) and δ is Dirac's delta function. In addition to this relation, expression (12) gives us the relationships between Benney equations and both shallow-water equations. In the case of reduced Benney equations, we can use the following relation:

$$\tilde{f}(\xi_1,\xi_2) = \tilde{h}(\xi_1)\delta(\tilde{u}(\xi_1) - \xi_2) \tag{13}$$

which have similar forms with relations (12). Then one may obtain a system of ordinary differential equations (ODE) by using the relations (12). In this section, we give an example of the application of symmetry groups.

For this purpose, we seek the solution for the reduced form of the Benney equations below:

$$(\xi_1 + \xi_2)\frac{\partial \tilde{f}(\xi_1,\xi_2)}{\partial \xi_1} - \frac{\partial \tilde{f}(\xi_1,\xi_2)}{\partial \xi_2}\int_{-\infty}^{\infty}\frac{\partial \tilde{f}(\xi_1,\xi_2)}{\partial \xi_1}d\xi_2 = 0, \tag{14}$$

which is a special form of the reduced form. Using the form (13) we get the following system of ODE:

$$\xi_1\tilde{h}'(\xi_1) + \tilde{h}'(\xi_1)\tilde{u}(\xi_1) + \tilde{h}(\xi_1)\tilde{u}'(\xi_1) = 0 \quad \text{and} \quad \tilde{u}(\xi_1)\tilde{u}'(\xi_1) + \xi_1\tilde{u}'(\xi_1) + \tilde{h}'(\xi_1) = 0 \tag{15}$$

from the solutions to the system of ODE in the similarity form,

$$\tilde{h}(\xi_1) = \frac{1}{9}\xi_1^2, \qquad \tilde{u}(\xi_1) = -\frac{2}{3}\xi_1. \tag{16}$$

These solutions correspond to the similarity solution of the classical case (11). One can write the equation (3) due to the solutions (16) in the variables x, t, and v as

$$f(x,t,v) = \frac{1}{9}(1-t)^{-2}(x-1)^2\delta\left(v + \frac{2}{3}(t-1)^{-1}(x-1)\right). \tag{17}$$

5 Conclusions

In this study, we obtained symmetry groups of Benney equations that are in the form of the system of IDE. As mentioned in the introduction, although the symmetry group analysis has many applications for the ODE and PDE in the literature, there are relatively few applications on symmetry group of IDE since there is no general method for solving determining equations. Several solution methods may be offered for investigating the determining equations for symmetry groups of problems including IDE. In the case of Benney equations investigated in the study by Krasnoslobodtsev [10] and Ibragimov et al. [11], symmetry groups of these equations

were investigated based on the canonical multiplication law and the methods of moments, respectively. In our study, we calculated the symmetry groups of Benney equations by using a different method, explained in the study. After calculations, it was found a five-parameter Lie group of transformations of Benney equations. These results are parallel to the results presented in Ibragimov's study based on using the canonical Lie–Bäcklund operators. These results are parallel to the results presented in Ibragimov's study based on using the canonical Lie–Bäcklund operators. We obtained the general reduced forms of Benney equations by using the characteristics based on symmetry groups. Then we obtained the general reduced forms of Benney equations by using the characteristics based on symmetry groups. One of the important advantages of investigating solutions of Benney equations is based on the fact that one may transform these solutions into solutions of the shallow-water equations and Benney equations derived form the two-dimensional Euler equations for inviscid, incompressible fluid, and from the reduced form of the equation. In the study, we showed a similarity solution for a reduced equation, and proved that each solution obtained from solutions of each reduced form of the systems of IDE can be used to obtain similarity solutions of Benney equations.

We perform the complete group classification in the class of cubic Schrödinger equations of the form $i\psi_t + \psi_{xx} + \psi^2\psi^* + V(t,x)\psi = 0$, where V is an arbitrary complex-valued potential depending on t and x. We construct all possible inequivalent potentials for which these equations have non-trivial Lie symmetries using algebraic and compatibility methods simultaneously. Our classification essentially amends earlier works on the subject.

Nonlinear Schrödinger equations (NSchEs) have a number of applications in wave propagation in inhomogeneous media. They arise as a model of plasma phenomena, namely, of different processes in nonlinear and non-uniform dielectric medium and in other branches of physics. Schrödinger equations have been investigated by means of symmetry methods by a number of authors, see e.g. [2–10] and references there. In fact, group classification for Schrödinger equations was first performed by S. Lie. More precisely, his classification [1] of all the linear equations with two independent complex variables contains, in an implicit form, solution of the classification problem for the linear (1+1)-dimensional Schrödinger equations with arbitrary potentials.

In this paper we study a class of NSchEs of the form

$$i\psi_t + \psi_{xx} + \psi^2\psi^* + V\psi = 0, \tag{1}$$

where the potential $V = V(t,x)$ is an arbitrary complex-valued smooth function of the variables t and x. (Here and below subscripts of functions denote differentiation with respect to the corresponding variables.) To find a complete set of inequivalent cases of V admitting extensions of the maximal Lie invariance algebra, we combine the classical Lie approach, studying the algebra generated by all the possible Lie symmetry operators for equations from class (1) (the adjoint representation, the inequivalent one-dimensional subalgebras etc.) and investigation of compatibility of classifying equations. See [2, 3, 11–13] for precise formulation of group classification problems and more details on the used methods.

Finishing excellent series of papers [8–10] on group analysis and exact solutions of NSchEs, in [10] L. Gagnon and P. Winternitz investigated essentially more general class of variable coefficient NSchEs than (1). Unfortunately, we were not able to see a direct and simple way for deducing classifications obtained here from their results.

Theorem 1. *Any operator* $Q = \xi^t\partial_t + \xi^x\partial_x + \eta\partial_\psi + \eta^*\partial_{\psi^*}$ *from the maximal Lie invariance algebra* $A^{\max}(V)$ *of equation* (1) *with arbitrary potential* V *lies in the linear span of operators of the form*

$$D(\xi) = \xi\partial_t + \tfrac{1}{2}\xi_t x\partial_x + \tfrac{1}{8}\xi_{tt}x^2M - \tfrac{1}{2}\xi_t I, \qquad G(\chi) = \chi\partial_x + \tfrac{1}{2}\chi_t xM, \qquad \lambda M. \tag{2}$$

Here $\chi = \chi(t)$, $\xi = \xi(t)$ *and* $\lambda = \lambda(t)$ *are arbitrary smooth functions of* t, $M = i(\psi\partial_\psi - \psi^*\partial_{\psi^*})$, $I = \psi\partial_\psi + \psi^*\partial_{\psi^*}$. *Moreover, the coefficients of* Q *should satisfy the classifying condition*

$$i\eta_{\psi t} + \eta_{\psi xx} + \xi^t V_t + \xi^x V_x + \xi^t_t V = 0. \tag{3}$$

Note 1. The linear span of operators of the form (2) is an (infinite-dimensional) Lie algebra $A^{\cup}$ under the usual Lie bracket of vector fields. Since for any $Q\in A^{\cup}$ where $(\xi^t,\xi^x)\neq(0,0)$ we can find V satisfying condition (3) then $A^{\cup}=\langle\bigcup_V A^{\max}(V)\rangle$. The non-zero commutation relations between the basis elements of $A^{\cup}$ are the following ones:

$$\big[D\big(\xi^1\big),D\big(\xi^2\big)\big]=D\big(\xi^1\xi^2_t-\xi^2\xi^1_t\big),\qquad [D(\xi),G(\chi)]=G\big(\xi\chi_t-\tfrac12\,\xi_t\chi\big),$$
$$[D(\xi),\lambda M]=\xi\lambda_t M,\qquad \big[G\big(\chi^1\big),G\big(\chi^1\big)\big]=\tfrac12\big(\chi^1\chi^2_t-\chi^2\chi^1_t\big)M.$$

We use the notation $\mathrm{Aut}(A^{\cup})$ for the automorphism group acting on $A^{\cup}$, which is generated by all the one-parameter groups corresponding to the adjoint representations of operators of $A^{\cup}$ into $A^{\cup}$ and two discrete transformations $\mathrm{Ad}\,I_x$ and $\mathrm{Ad}\,I_t$ included additionally. The actions of $\mathrm{Ad}\,I_x$ and $\mathrm{Ad}\,I_t$ on the basis elements of $A^{\cup}$ are defined by the formulas $\mathrm{Ad}\,I_x\ G(\chi)=G(-\chi)$ (the other basis operators do not change) and $\mathrm{Ad}\,I_t\ D(\xi)=D(\tilde\xi)$, $\mathrm{Ad}\,I_t\ G(\chi)=G(\tilde\chi)$, $\mathrm{Ad}\,I_t\ \lambda M=\tilde\lambda M$, where $\tilde\xi(t)=-\xi(-t)$, $\tilde\chi(t)=\chi(-t)$ and $\tilde\lambda(t)=-\lambda(-t)$.

Theorem 2. *The Lie algebra of the kernel of maximal Lie invariance groups of equations from class* (1) *is* $A^{\ker}=\langle M\rangle$.

Theorem 3. *The Lie algebra* A^{equiv} *of the equivalence group* G^{equiv} *of the class* (1) *is generated by the operators*

$$D'(\xi)=D(\xi)+\tfrac18\xi_{ttt}x^2(\partial_V+\partial_{V^*})+\tfrac{i}{2}\xi_{tt}(\partial_V-\partial_{V^*})-\xi_t(V\partial_V+V^*\partial_{V^*}),$$
$$G'(\chi)=G(\chi)+\tfrac12\chi_{tt}x(\partial_V+\partial_{V^*}),\qquad M'(\lambda)=\lambda M+\lambda_t(\partial_V+\partial_{V^*}).$$

Therefore, $A^{\mathrm{equiv}}\simeq A^{\cup}$, *and the isomorphism is determined by means of prolongation of operators from* $A^{\cup}$ *to the space* (V,V^*).

Theorem 4. *The equivalence group* G^{equiv} *of the class* (1) *is generated by the family of continuous transformations*

$$\begin{aligned}&\tilde t=T,\quad \tilde x=x\varepsilon\sqrt{T_t}+X,\quad \tilde\psi=\psi\frac{1}{\sqrt{T_t}}\exp\left(\frac{i}{8}\frac{T_{tt}}{T_t}\,x^2+\frac{i}{2}\frac{X_t}{\sqrt{T_t}}\,x+i\Psi\right),\\ &\tilde V=\frac{1}{T_t}\left(V+\frac18\left(\frac{T_{tt}}{T_t}\right)_t x^2+\frac12\left(\frac{X_t}{\sqrt{T_t}}\right)_t x+\frac{i}{4}\frac{T_{tt}}{T_t}-\left(\frac14\frac{T_{tt}}{T_t}\,x+\frac12\frac{X_t}{\sqrt{T_t}}\right)^2+\Psi_t\right),\end{aligned}\tag{4}$$

and two discrete transformations: the space reflection I_x *(*$\tilde t=t$, $\tilde x=-x$, $\tilde\psi=\psi$, $\tilde V=V$*) and the Wigner time reflection* I_t *(*$\tilde t=-t$, $\tilde x=x$, $\tilde\psi=\psi^*$, $\tilde V=V^*$*). Here* T, X *and* Ψ *are arbitrary smooth functions of* t, $T_t>0$.

Corollary 1. 1. $G^{\mathrm{equiv}}\simeq\mathrm{Aut}\,A^{\cup}$. 2. *Let* A^1 *and* A^2 *be the maximal Lie invariance algebras of equations from class* (1) *for some potentials, and* $\mathcal{V}^i=\{V\,|\,A^{\max}(V)=A^i\}$, $i=1,2$. *Then* $\mathcal{V}^1\sim\mathcal{V}^2 \bmod G^{\mathrm{equiv}}$ *iff* $A^1\sim A^2 \bmod \mathrm{Aut}\,A^{\cup}$.

Lemma 1. *A complete list of* $\mathrm{Aut}\,A^{\cup}$*-inequivalent one-dimensional subalgebras of* $A^{\cup}$ *is exhausted by the algebras* $\langle\partial_t\rangle$, $\langle\partial_x\rangle$, $\langle tM\rangle$, $\langle M\rangle$.

Proof. Consider any operator $Q\in A^{\cup}$, i.e. $Q=D(\xi)+G(\chi)+\lambda M$. Depending on the values of ξ, χ and λ it is equivalent under $\mathrm{Aut}\,A^{\cup}$ and multiplication by a number to one from the following operators: $D(1)$ if $\xi\neq0$; $G(1)$ if $\xi=0$ and $\chi\neq0$; tM if $\xi=\chi=0$, $\lambda_t\neq0$; M if $\xi=\chi=\lambda_t=0$. ■

Corollary 2. *If* $A^{\max}(V)\neq A^{\ker}$ *then* $V_tV_x=0 \bmod G^{\mathrm{equiv}}$.

Proof. Under the corollary assumption there exists an operator $Q = D(\xi) + G(\chi) + \lambda M \in A^{\max}(V)$ which do not belong to $\langle M\rangle$. Condition (3) implies $(\xi,\chi) \neq (0,0)$. Therefore, in force of Lemma 1 $\langle Q\rangle \sim \langle\partial_t\rangle$ or $\langle\partial_x\rangle$ mod $\operatorname{Aut} A^{\cup}$, i.e. $V_tV_x = 0$ mod G^{equiv}. ■

Theorem 5. *A complete set of inequivalent cases of V admitting extensions of the maximal Lie invariance algebra of equations* (1) *is exhausted by the potentials given in Table 1.*

Table 1. Results of classification. Here $W(t), \nu, \alpha, \beta \in \mathbb{R}$, $(\alpha,\beta) \neq (0,0)$.

N	V	Conditions mod G^{equiv}	Basis of $A^{\max}$
0	$V(t,x)$		M
1	$iW(t)$		$M,\ \partial_x,\ G(t)$
2	$\frac{i}{2}\frac{t+\nu}{t^2+1}$	$\nu \geq 0$	$M,\ \partial_x,\ G(t),\ D(t^2+1)$
3	$i\nu t^{-1},\ \nu \neq 0, \frac{1}{2}$	$\nu \geq \frac{1}{4}$	$M,\ \partial_x,\ G(t),\ D(t)$
4	i		$M,\ \partial_x,\ G(t),\ \partial_t$
5	0		$M,\ \partial_x,\ G(t),\ \partial_t,\ D(t)$
6	$V(x)$		$M,\ \partial_t$
7	$(\alpha+i\beta)x^{-2}$	$\beta \geq 0$	$M,\ \partial_t,\ D(t)$

If we use Corollary 2, then to prove Theorem 5 it is sufficient to study two cases: $V_x = 0$ and $V_t = 0$. In fact, below we obtain the complete results of group classifications for both special cases and then unite them for the general case under consideration.

Lemma 2. *Let $V_x = 0$, i.e. $V = V(t)$.*

1. $A^{\ker}_{V_x=0} = \langle M, G(1), G(t)\rangle$. $A^{\text{equiv}}_{V_x=0} = \langle M'(\lambda)\ \forall\lambda = \lambda(t), G'(1), G'(t), D'(1), D'(t), D'(t^2)\rangle$. $G^{\text{equiv}}_{V_x=0}$ *is generated by I_t, I_x and the transformations of form* (4) *where $X = c_1t + c_0$, $T = (a_1t+a_0)/(b_1t+b_0)$, Ψ is an arbitrary smooth function of t. a_i, b_i and c_i are arbitrary constants such that $a_1b_0 - b_1a_0 > 0$.*

2. $V \sim iW$ mod $G^{\text{equiv}}_{V_x=0}$ *where* $W = \operatorname{Im} V$. $A^{\max}(iW) \subset A^{\cup}_{\{iW\}} = A^{\ker}_{V_x=0} \ni \langle D(1), D(t), D(t^2)\rangle$. $A^{\ker}_{\{iW\}} = A^{\ker}_{V_x=0}$. $A^{\cup}_{\{iW\}} = \langle \bigcup_W A^{\max}(iW)\,\rangle$. $A^{\text{equiv}}_{\{iW\}} = \langle M, G'(1), G'(t), D'(1), D'(t), D'(t^2)\rangle$. $G^{\text{equiv}}_{\{iW\}} = G^{\text{equiv}}_{V_x=0}\big|_{\Psi=\text{const}}$. $A^{\cup}_{\{iW\}} \simeq A^{\text{equiv}}_{\{iW\}} = \operatorname{pr}_{(V,V^*)} A^{\cup}_{\{iW\}}$.

3. $S = \langle D(1), D(t), D(t^2)\rangle \simeq sl(2,\mathbb{R})$. *The complete list of* $\operatorname{Aut} A^{\cup}_{\{iW\}}$*-inequivalent proper subalgebras of S is exhausted by* $\langle D(1)\rangle$, $\langle D(t)\rangle$, $\langle D(t^2+1)\rangle$, $\langle D(1), D(t)\rangle$.

4. *Let A^1 and A^2 be the maximal Lie invariance algebras of equations from class (1) for some potentials from $\{iW(t)\}$, and $\mathcal{W}^i = \{\, W(t) \,|\, A^{\max}(iW) = A^i\}$, $i = 1,2$. Then $\mathcal{W}^1 \sim \mathcal{W}^2$* mod $G^{\text{equiv}}_{\{iW\}}$ *iff $A^1 \bigcap S \sim A^2 \bigcap S$* mod $\operatorname{Aut} S$.

5. *If $A^{\max}_{\{iW\}} \neq A^{\ker}_{V_x=0}$ the potential $iW(t)$ is $G^{\text{equiv}}_{\{iW\}}$-equivalent to one from Cases 2–5 of Table 1.*

Note 2. For any W $A^{\max}(iW) \not\supset S$ (otherwise, condition (3) would imply an incompatible system for W). If $W = \text{const}$ $W \in \{0,1\}$ mod $G^{\text{equiv}}_{\{iW\}}$ (Cases 5 and 4 correspondingly). Cases 2_ν and $2_{\tilde\nu}$ (3_ν and $3_{\tilde\nu}$ where $\nu, \tilde\nu \geq \frac{1}{4}$) are G^{equiv}-inequivalent if $\nu \neq \tilde\nu$. Since $D(t^2+1)$ cannot be contained in any two-dimensional subalgebra of S it is not possible to extend $A^{\max}$ in Case 2. There are two possibilities for extension of $A^{\max}(i\nu t^{-1})$, namely with either $D(1)$ (for $\nu = 0$, Case 5) or $D(t^2)$ (for $\nu = \frac{1}{2}$ that is equivalent to Case 5 with respect to $G^{\text{equiv}}_{\{iW\}}$).

Lemma 3. *Let $V_t = 0$, i.e. $V = V(x)$.*

1. *$A^{\ker}_{V_t=0} = \langle M, D(1)\rangle$. $A^{\rm equiv}_{V_t=0} = \langle M'(1), M'(t), G'(1), D'(1), D'(t)\rangle$. $G^{\rm equiv}_{V_t=0}$ consists of I_t, I_x and the transformations of form (4) where $T_{tt} = X_t = \Psi_{tt} = 0$.*
2. *If $A^{\max}(V) \neq A^{\ker}_{V_t=0}$ the potential $V(x)$ is $G^{\rm equiv}_{V_t=0}$-equivalent to one from cases of Table 2.*

Table 2. Results of classification for the subclass $\{V = V(x)\}$. Here $\nu, \alpha, \beta \in \mathbb{R}$, $(\alpha, \beta) \neq (0, 0)$.

N	N_1	V	mod $G^{\rm equiv}$	Basis of $A^{\max}$
0	6	$V(x)$		$M,\ \partial_t$
1	7	$(\alpha+i\beta)x^{-2}$	$\beta \geq 0$	$M,\ \partial_t,\ D(t)$
2	7	$x^2 + i + (\alpha+i\beta)x^{-2}$		$M,\ \partial_t,\ D(e^{4t})$
3	4	i		$M,\ \partial_t,\ \partial_x,\ G(t)$
4	4	$x + i\nu$	$\nu > 0$	$M,\ \partial_t,\ G(1)+tM,\ G(2t)+t^2M$
5	2	$-x^2 + i\nu$	$\nu \geq 0$	$M,\ \partial_t,\ G(\sin 2t),\ G(\cos 2t)$
6	3	$x^2 + i\nu,\ \nu \neq \pm 1$	$\nu \geq 0$	$M,\ \partial_t,\ G(e^{2t}),\ G(e^{-2t})$
7	5	0		$M,\ \partial_t,\ \partial_x,\ G(t),\ D(t)$
8	5	x		$M,\ \partial_t,\ G(1)+tM,\ G(2t)+t^2M,\ D(2t)+G(3t^2)+t^3M$
9	5	$x^2 + i$		$M,\ \partial_t,\ G(e^{2t}),\ G(e^{-2t}),\ D(e^{4t})$

Proof. 2. Let $V = V(x)$ and $A^{\max}(V) \neq A^{\ker}_{V_t=0}$. Consider an arbitrary operator $Q = D(\xi) + G(\chi) + \lambda M \in A^{\max}(V)$. Under Lemma's assumption, the condition (3) implies a set of equations on V of the general form

$$(ax+b)V_x + 2aV = c_2x^2 + c_1x + \tilde{c}_0 + ic_0, \qquad \text{where} \quad a, b, c_2, c_1, \tilde{c}_0, c_0 = \text{const} \in \mathbb{R}.$$

The exact number k of such equations with the linear independent sets of coefficients can be equal to either 1 or 2. (The value $k = 0$ corresponds to the general case $V_t = 0$ without any extensions of $A^{\max}$.)

For $k = 1$ $(a, b) \neq (0, 0)$ and there exist two possibilities $a = 0$ and $a \neq 0$. If $a = 0$ without loss of generality we can put $b = 1$. Condition (3) results in $\xi_t = 0$, $c_2 = c_0 = 0$, i.e. $V_x = c_1x + \tilde{c}_0$, and then $k = 2$ that is impossible.

Therefore, $a \neq 0$ and we can put $a = 1$. $\tilde{c}_0, b = 0 \bmod G^{\rm equiv}_{V_t=0}$. Condition (3) results in $\chi = 0$ (then $c_1 = 0$), $\lambda_t = 0$, $\xi_{tt} = 2c_0\xi_t$ and $c_2 = c_0^2$. Depending on $c_0 = 0$ and $c_0 \neq 0$, we obtain Cases 1 and 2 (of Table 2) correspondingly.

The condition $k = 2$ involves $V = d_2x^2 + d_1x + \tilde{d}_0 + id_0$. $\tilde{d}_0 = 0 \bmod G^{\rm equiv}_{V_t=0}$. Considering different possibilities for values of the constants d_2, d_1 and d_0, we obtain Cases 3–9:

$$d_2 = d_1 = d_0 = 0 \ \to\ 7; \qquad d_2 = d_1 = 0,\ d_0 \neq 0 \ \to\ 3;$$
$$d_2 = d_0 = 0,\ d_1 \neq 0 \ \to\ 8; \qquad d_2 = 0,\ d_0, d_1 \neq 0 \ \to\ 4;$$
$$d_2 < 0 \ \to\ 5; \qquad d_2 > 0,\ d_2 \neq d_0^2 \ \to\ 6; \qquad d_2 > 0,\ d_2 = d_0^2 \ \to\ 9.$$

Note 3. To prove Theorem 5, it is sufficient to consider only the case $k = 1$, $a \neq 0$ in Lemma 3 since the other cases of extensions of $A^{\max}(V)$ with $V = V(x)$ admit operators of the form $G(\chi) + \lambda M$ $(\chi \neq 0)$ and, therefore (by Corollary 1), are equivalent to Cases 1–5 of Table 1.

Note 4. The number N_1 for each line of Table 2 is equal to the number of the same or equivalent case in Table 1. The corresponding equivalence transformations have the form (4) where the functions T, X and Ψ are as follows:

$$2 \to 7,\ 9 \to 5: \quad T = -e^{-4t},\ X = \Psi = 0;$$
$$6 \to 3(\tilde{\nu} = \tfrac{1-\nu}{4}): \quad T = -e^{-4t},\ X = \Psi = 0; \qquad 5 \to 2(\tilde{\nu} = \nu): \quad T = \tan 2t,\ X = \Psi = 0;$$
$$8 \to 5: \quad T = t,\ X = -t^2,\ \Psi = \frac{t^3}{3}; \qquad 4 \to 4: \quad T = |\nu|t,\ X = -\sqrt{|\nu|}\,t^2,\ \Psi = \frac{t^3}{3}.$$

The results of the group classification obtained in this paper can be used to construct both invariant and partially invariant exact solutions of equations having the form (1). Moreover, we plan to study conditional symmetries of (1) to find non-Lie exact solutions.

Another direction for our future research to develop the above results is investigation of a more general class of $(1+n)$-dimensional NSchEs with potentials

$$i\psi_t + \Delta\psi + F(\psi,\psi^*) + V(t,\vec{x})\psi = 0, \tag{5}$$

where the $F = F(\psi,\psi^*)$ is an arbitrary complex-valued smooth function of the variables ψ and ψ^*. We have already described all possible inequivalent forms of the parameter-function F (without any restriction on the dimension n) for which an equation of the form (5) with a some potential V has an extension of the maximal Lie invariance algebra. We believe that the classification method suggested in this paper can be effectively applied to complete the group classification in (5) for the small values of n.

Acknowledgements

Universal Structure of Jet Space

Maido RAHULA

Institute of Pure Mathematics, University of Tartu, 2 Liivi, 50409 Tartu, Estonia
E-mail: *Maido.Rahula@math.ut.ee*

Operators of total differentiation D, Cartan forms ω and infinitesimal symmetries P constitute the structure of infinite jet space $J_{n,m}$. We describe these notions compactly for the space $J_{1,1}$ though reserve the possibility to pass with the help of multi-indices to general case $J_{n,m}$. Our aim is to show the universality of this structure. Every time when we differentiate a function f with respect to the vector field X on a manifold M we can determine a map $\varphi : M \to J_{1,1}$ and connect the triple (X, s, F) with the triple (D, t, U) in $J_{1,1}$, where F is the set of derivatives $f^{(k)} = X^k f$, $k = 0, 1, 2, \ldots$; s is canonical parameter of X, U is the set of fiber coordinates $u^{(k)} = D^k u$, $k = 0, 1, 2, \ldots$, and t is canonical parameter of D. Then all the invariants and symmetries of D as well as all the covariant tensors including Cartan forms can be transformed from $J_{1,1}$ onto the manifold M. The structure is universal as final object in the category of triples (X, s, F).

Let $f : V_n \to V_m$ be a smooth mapping. The infinite jet of the map f is determined by the coordinates t^i, u^α of the points $t \in V_n$ and $u = f(t) \in V_m$, and by the values of partial derivatives at t:

$$u^\alpha_i = \frac{\partial f^\alpha}{\partial u^i}(t), \quad u_{ij} = \frac{\partial^2 f^\alpha}{\partial u^i \partial u^j}(t), \quad \ldots,$$
$$i, j = 1, 2, \ldots, \quad n = \dim V_n, \quad \alpha = 1, 2, \ldots, \quad m = \dim V_m.$$

The set of the jets of f is called *jet space* $J_{m,n}$ where the quantities

$$t^i, \quad u^\alpha, \quad u^\alpha_i, \quad u^\alpha_{ij}, \quad \ldots \tag{1}$$

are *jet coordinates*.

In the space $J_{1,1}$ we have the coordinates

$$t, \quad u, \quad u', \quad u'', \quad \ldots \tag{2}$$

or briefly (t, U) where U is the column of elements $u, u', u'', \ldots$.

In $J_{1,1}$ one has the *natural basis* $\left(\frac{\partial}{\partial t}, \frac{\partial}{\partial U}; dt, dU\right)$ associated with the coordinates (2). Here $\frac{\partial}{\partial U}$ is the row of elements $\frac{\partial}{\partial u}, \frac{\partial}{\partial u'}, \ldots$ and dU is the column of elements $du, du', du'', \ldots$.

Let us introduce the infinite-dimensional unit matrix E and the shift matrix C as follows:

$$E = \begin{pmatrix} 1 & 0 & 0 & \cdot \\ 0 & 1 & 0 & \cdot \\ 0 & 0 & 1 & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{pmatrix}, \qquad C = \begin{pmatrix} 0 & 1 & 0 & \cdot \\ 0 & 0 & 1 & \cdot \\ 0 & 0 & 0 & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{pmatrix}$$

and define in $J_{1,1}$ the *total differentiation operator* by formula:

$$D = \frac{\partial}{\partial t} + \frac{\partial}{\partial U} U', \qquad \text{where} \qquad U' = CU. \tag{3}$$

Proposition 1. *The operator D is a linear vector field in the jet space $J_{1,1}$ and its flow is determined by exponential law (see [5]),*

$$U' = CU \quad \Rightarrow \quad U_t = e^{Ct} U. \tag{4}$$

The curves (t, U_t) are the trajectories of D.

Proposition 2. *If the operator $\frac{\partial}{\partial t}$ in the frame $\left(\frac{\partial}{\partial t}, \frac{\partial}{\partial U}\right)$ is replaced by D then the differentials dU in the coframe (dt, dU) have to be replaced by Cartan forms*

$$\omega = dU - U'dt. \tag{5}$$

The new basis in the matrix form

$$\begin{pmatrix} D & \frac{\partial}{\partial U} \end{pmatrix} = \begin{pmatrix} \frac{\partial}{\partial t} & \frac{\partial}{\partial U} \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ U' & E \end{pmatrix}, \qquad \begin{pmatrix} dt \\ \omega \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ -U' & E \end{pmatrix} \cdot \begin{pmatrix} dt \\ dU \end{pmatrix}.$$

is called *adapted basis* in $J_{1,1}$. The term "adapted basis" proceeds from the theory of connections (see [4, p. 23]).

Proposition 3. *The derivation formulae valid for the adapted basis (vertical part):*

$$\left(\frac{\partial}{\partial U}\right)' = -\frac{\partial}{\partial U}C, \qquad \omega' = C\omega. \tag{6}$$

The stroke means Lie derivative with respect to D. The frame $\frac{\partial}{\partial U}$ and the coframe ω are transported by the flow of D according to the law (4):

$$\left(\frac{\partial}{\partial U}\right)' = -\frac{\partial}{\partial U}C \qquad \Rightarrow \qquad \left(\frac{\partial}{\partial U}\right)_t = \frac{\partial}{\partial U}e^{-Ct},$$
$$\omega' = C\omega \qquad \Rightarrow \qquad \omega_t = e^{Ct}\omega.$$

Proposition 4. *The quantities*

$$I = e^{-Ct}U \tag{7}$$

are the invariants of D because $I' = e^{-Ct}(U' - CU) = 0$. Replacing U by I in the fibers of $J_{1,1}$ we have the invariant basis:

$$\left(\frac{\partial}{\partial t}, \frac{\partial}{\partial I}; dt, dI\right).$$

The exponential e^{-Ct} is *integrating matrix* for Cartan forms ω and the operators $\frac{\partial}{\partial I}$ are *infinitesimal symmetries* of D (*infinitesimals* after [1]) in the following sense:

$$dI = e^{-Ct}\omega, \qquad \frac{\partial}{\partial I} = \frac{\partial}{\partial U}e^{Ct}. \tag{8}$$

Infinitesimal symmetries of D are called *Lie vector fields* in $J_{1,1}$.

Proposition 5. *A vector field P written in three frames of $J_{1,1}$, natural, adapted and invariant as follows*

$$P = \frac{\partial}{\partial t}\xi + \frac{\partial}{\partial U}\lambda = D\xi + \frac{\partial}{\partial U}\mu = \frac{\partial}{\partial t}\xi + \frac{\partial}{\partial I}\nu \tag{9}$$

has for components the entities

$$\xi = Pt, \qquad \lambda = PU, \qquad \mu = \omega(P), \qquad \nu = PI, \tag{10}$$

with relations

$$\nu = e^{-Ct}\mu, \qquad \mu = \lambda - U'\xi. \tag{11}$$

The field P is a Lie vector field if and only if one of equivalent conditions is satisfied:

$$\nu' = 0, \qquad \mu' = C\mu, \qquad \lambda' = C\lambda + U'\xi'. \tag{12}$$

It is obvious from the Lie derivatives:

$$P' = D\xi' + \frac{\partial}{\partial U}(\lambda' - C\lambda - U'\xi') = D\xi' + \frac{\partial}{\partial U}(\mu' - C\mu) = D\xi' + \frac{\partial}{\partial I}\nu',$$
$$L_p\omega = (\lambda' - C\lambda - U'\xi')dt + \left(\frac{\partial\lambda}{\partial U} - U'\frac{\partial\xi}{\partial U}\right)\omega = (\mu' - C\mu)dt + \frac{\partial\mu}{\partial U}\omega = e^{Ct}\nu' dt + \frac{\partial\nu}{\partial I}\omega.$$

The most simple condition $\nu' = 0$ says that the components ν in invariant frame are invariants of D.

The condition $\mu' = C\mu$ means that each entry of column μ is the derivative of preceding entry. Thus all entries of column μ in adapted frame are generated by the first entry $\mu_0 = f$ (*generating function*, see [1, p. 454]) by means of differentiation:

$$\mu_k = f^{(k)} = D^k f, \qquad k = 0, 1, 2, \ldots.$$

There is an obvious analogy between two equations $I = e^{-Ct}U$ and $v = e^{-Ct}\mu$.

The most complicated condition $\lambda' = C\lambda + U'\xi'$ is principal for the calculation of symmetries in natural basis (see [1, p. 244], [2, p. 110], [3, p. 55]).

Remark 1. In $J_{1,1}$ the invariants $I = e^{-Ct}U$ are described as follows:

$$I_k = \sum_{\ell=0}^{\infty} u^{(k+\ell)}\frac{(-t)^\ell}{\ell!}, \qquad k = 0, 1, 2, \ldots.$$

The operators $\frac{\partial}{\partial I}$ are basic Lie vector fields with generating functions $1, t, \frac{t^2}{2}, \ldots$ respectively, that is

$$\frac{\partial}{\partial I_0} = \frac{\partial}{\partial u},$$
$$\frac{\partial}{\partial I_1} = t\frac{\partial}{\partial u} + \frac{\partial}{\partial u'},$$
$$\frac{\partial}{\partial I_2} = \frac{t^2}{2}\frac{\partial}{\partial u} + t\frac{\partial}{\partial u'} + \frac{\partial}{\partial u''}$$
$$\ldots\ldots\ldots\ldots\ldots\ldots\ldots$$

Remark 2. In $J_{n,m}$ instead of D we have a system of n operators D_i, $i = 1, 2, \ldots, n$, and instead of 1-dimensional trajectories we have n-dimensional orbits of the additive group $\mathbb{R}^n$. For example, in the space $J_{2,1}$ there are the 2-dimensional time $t = (t_1, t_2)$ and two operators

$$D_1 = \frac{\partial}{\partial t_1} + u_1\frac{\partial}{\partial u} + u_{11}\frac{\partial}{\partial u_1} + u_{12}\frac{\partial}{\partial u_2} + \cdots,$$
$$D_2 = \frac{\partial}{\partial t_2} + u_2\frac{\partial}{\partial u} + u_{12}\frac{\partial}{\partial u_1} + u_{22}\frac{\partial}{\partial u_2} + \cdots.$$

Herewith 2-dimensional orbits of $\mathbb{R}^2$ are determined by the series

$$u_t = u + u_1t_1 + u_2t_2 + \frac{1}{2}\left[u_{11}(t_1)^2 + 2u_{12}t_1t_2 + u_{22}(t_2)^2\right] + \cdots$$

and its partial derivatives of all orders with respect to t_1 and t_2.

Remark 3. In $J_{2,1}$ the Lie field P with the generating function f can be represented in adapted and natural basis as follows:

$$P = \xi^1 D_1 + \xi^2 D_2 + f\frac{\partial}{\partial u} + f_1\frac{\partial}{\partial u_1} + f_2\frac{\partial}{\partial u_2} + \cdots$$

$$= \xi^1 \frac{\partial}{\partial t_1} + \xi^2 \frac{\partial}{\partial t_2} + \left(f + u_1\xi^1 + u_2\xi^2\right) \frac{\partial}{\partial u} + \left(f_1 + u_{11}\xi^1 + u_{12}\xi^2\right) \frac{\partial}{\partial u_1}$$
$$+ \left(f_2 + u_{12}\xi^1 + u_{22}\xi^2\right) \frac{\partial}{\partial u_2} + \cdots ,$$

where $f_i = D_i f$, $i = 1, 2$. The components $\lambda_k = f_k + u_{ki}\xi^i$, $k = 0, 1, 2, \ldots$ are consistent with the relation $\lambda = \mu + U'\xi$.

Theorem 1. *Any smooth vector field X without singularities on a manifold M can be connected with the total differentiation operator D in the jet space $J_{1,1}$, i.e. there exists a smooth map $\varphi : M \longrightarrow J_{1,1}$ such that the vector field X is φ-connected with the operator D.*

Proof. Let s be the canonical parameter of the vector field X, herewith $Xs = 1$. Take a smooth function f and calculate its derivatives with respect to X, $f^{(k)} = X^k f$, $k = 1, 2, \ldots$. Let F be the infinite column of elements $f, f', f'', \ldots$ and let us define the mapping φ by the relations

$$t \circ \varphi = s, \qquad U \circ \varphi = F. \tag{13}$$

At some step n we get the conditions

$$\Theta = df \wedge df' \wedge df'' \wedge \cdots \wedge df^{(n-1)} \neq 0 \qquad \text{and} \qquad \Theta \wedge df^{(n)} = 0. \tag{14}$$

There are two possible cases: a) $n = \dim M$, or b) $n < \dim M$.

Case a) $n = \dim M$. Let the functions $f, f', f'', \ldots, f^{(n-1)}$ be the coordinates on M and let us represent the field X as follows:

$$X = f' \frac{\partial}{\partial f} + f'' \frac{\partial}{\partial f'} + \cdots + f^{(n)} \frac{\partial}{\partial f^{(n-1)}}.$$

The Jacobian matrix of φ relate the components of X to the components of D (the subscripts mean the partial derivatives):

$$\begin{pmatrix} s_1 & \cdots & s_n \\ 1 & \cdots & 0 \\ \cdots & \cdots & \cdots \\ 0 & \cdots & 1 \\ f_1^{(n)} & \cdots & f_n^{(n)} \\ \cdots & \cdots & \cdots \end{pmatrix} \cdot \begin{pmatrix} f' \\ \cdots \\ f^{(n)} \end{pmatrix} = \begin{pmatrix} s' \\ f' \\ \cdots \\ f^{(n)} \\ f^{(n+1)} \\ \cdots \end{pmatrix} = \begin{pmatrix} 1 \\ u' \\ \cdots \\ u^{(n)} \\ u^{(n+1)} \\ \cdots \end{pmatrix} \circ \varphi.$$

The rank of the Jacobian matrix is equal to n and φ is an immersion of M into $J_{1,1}$. The triple (X, s, F) on the manifold M is φ-connected with the triple (D, t, U) in the jet space $J_{1,1}$.

Case b) $n < N = \dim M$. It follows from $\Theta \wedge df^{(n)} = 0$ that $df^{(n)}$ is a linear combination of $df, df', df'', \ldots, df^{(n-1)}$,

$$df^{(n)} = \sum_{i=1}^{n} \alpha_i df^{(n-i)} \qquad \text{and} \qquad L_X\Theta = \alpha_1\Theta.$$

The functions $f, f', f'', \ldots, f^{(n-1)}$ determine a submersion $\pi : M \longrightarrow W$. The vector field X transports the fibers of π into the fibers of the same bundle and because of this the field X can be projected on the n-dimensional manifold W. In the coordinates $v^{(i)}$,

$$v^{(i)} \circ \pi = f^{(i)}, \qquad i = 0, 1, 2, \ldots, n-1,$$

the projection of X is a vector field

$$T\pi X = v'\frac{\partial}{\partial v} + v''\frac{\partial}{\partial v'} + \cdots + v^{(n-1)}\frac{\partial}{\partial v^{(n-2)}} + f^{(n)}\frac{\partial}{\partial v^{(n-1)}}$$

which can be connected by a map $\tilde{\varphi} : W \longrightarrow J_{1,1}$ with the operator D. Then the vector field X is φ-connected with D, where $\varphi = \tilde{\varphi} \circ \pi$.

General case. How to make the correspondence between a system of n vector fields Y_i on a manifold M with the operators of total differentiation D_i in the jet space $J_{n,m}$? Let u^α be the coordinates on M, u^i the canonical parameters of Y_i, $Y_i u^j = \delta_i^j$, and y_i^α the natural components of the fields Y_i. The operators

$$X_i = \frac{\partial}{\partial u^i} + Y_i = \frac{\partial}{\partial u^i} + y_i^\alpha \frac{\partial}{\partial u^\alpha}$$

determine a n-dimensional distribution in the "space-time" $R^n \times M$ with the coordinates (u^i, u^α), $i = 1, 2, \ldots, n$; $\alpha = n+1, \ldots, n+m$; $m = \dim M$. This is a particular case of connection in the fiber space, see [4], where the operators

$$X_i = \frac{\partial}{\partial u^i} + \Gamma_i^\alpha \frac{\partial}{\partial u^\alpha} \tag{15}$$

form in the coordinates (u^i, u^α) an adapted frame of the horizontal distribution Δ_h, with the components

$$\Gamma_i^\alpha = \Gamma_i^\alpha(u^j, u^\beta).$$

In our case we have $\Gamma_i^\alpha = y_i^\alpha(u^j)$. Let us immerse the operators X_i in the space $J_{n,m}$ with the help of the map $\varphi : M \longrightarrow J_{n,m}$ supposing

$$\begin{aligned} &t^i \circ \varphi = u^i, \quad u^\alpha \circ \varphi = u^\alpha, \quad u_i^\alpha \circ \varphi = \Gamma_i^\alpha, \\ &u_{ij}^\alpha \circ \varphi = X_{(i}\Gamma_{j)}^\alpha, \quad u_{ijk}^\alpha \circ \varphi = X_{(i}X_j\Gamma_{k)}^\alpha, \quad \ldots. \end{aligned} \tag{16}$$

The operators X_i and the vector fields Y_i are φ-connected with the operators D_i. ■

As corollaries we have the next Propositions.

Proposition 6. *If the vector field X is φ-connected with the operator D then for any function I in $J_{1,1}$ the derivatives $X(I \circ \varphi)$ and DI are φ-connected, i.e. $X(I \circ \varphi) = (DI) \circ \varphi$. From this it follows that $DI = 0 \Longrightarrow X(I \circ \varphi) = 0$ and all the invariants of D can be transported on the manifold M in the invariants of the vector field X. In particular the invariants $I = e^{-Ct}U$ are transported from $J_{1,1}$ on M in the invariants $I \circ \varphi = e^{-Cs}F$.*

Proposition 7. *If the vector field X is φ-connected with the operator D then all the covariant tensors can be transported from $J_{1,1}$ on the manifold M. For example, the Cartan forms $\omega = dU - U'dt$ can be transported in the forms $\omega \circ T\varphi = dF - F'dt$, where $F' = XF$. The sequence of Lie derivatives with respect to D (Cartan forms)*

$$\omega_0 = du - u'dt, \quad \omega_0' = du' - u''dt, \quad \omega_0'' = du'' - u''dt, \quad \ldots$$

induces the sequence of Lie derivatives with respect to X:

$$\omega_0 \circ T\varphi = df - f'ds, \quad \omega_0' \circ T\varphi = df' - f''ds, \quad \omega_0'' \circ T\varphi = df'' - f'''ds, \quad \ldots.$$

Proposition 8. *In the general case (16) the Cartan forms in $J_{n,m}$*

$$\omega^\alpha = du^\alpha - u^\alpha dt^i, \quad \omega_i^\alpha = du_i^\alpha - u_{ij}^\alpha dt^j, \quad \dots$$

induce on the manifold $\mathbb{R}^n \times M$ the sequence of 1-forms

$$\theta^\alpha = \omega^\alpha \circ T\varphi = du^\alpha - \Gamma_i^\alpha du^i, \quad \theta_i^\alpha = \omega_i^\alpha \circ T\varphi = d\Gamma_i^\alpha - X_{(i}\Gamma_{j)}^\alpha du^j, \quad \dots.$$

The horizontal distribution Δ_h is the annulator of the forms θ^α, i.e. $\theta^\alpha(X_i) = 0$. The forms θ_i^α imply the appearance of two important objects:

$$K_{ij}^\alpha = X_{[i}\Gamma_{j]}^\alpha, \quad \text{object of curvature,}$$
$$\Gamma_{i\beta}^\alpha = -\partial_\beta \Gamma_i^\alpha, \quad \text{object of connection.}$$

Namely, because $d\Gamma_i^\alpha = X_j\Gamma_i^\alpha du^j + \partial_\beta \Gamma_i^\alpha \theta^\beta$ and $X_j\Gamma_i^\alpha = X_{(i}\Gamma_{j)}^\alpha - X_{[i}\Gamma_{j]}^\alpha$ we have

$$\theta_i^\alpha = -K_{ij}^\alpha du^j - \Gamma_{i\beta}^\alpha \theta^\beta.$$

For the linear connection the quantities Γ_i^α are linear functions on the fibers: $\Gamma_i^\alpha = -\Gamma_{i\beta}^\alpha u^\beta$, and we have $K_{ij}^\alpha = -K_{ij\beta}^\alpha u^\beta$, where $K_{ij\beta}^\alpha = \partial_{[i}\Gamma_{j]\beta}^\alpha + \Gamma_{[i|\gamma|}^\alpha \Gamma_{j]\beta}^\gamma$, (see [4, p. 26]).

Extending the linear connection onto the tangent bundle $TM \longrightarrow M$ we get the affine connection on the manifold M in the classical sense.

Proposition 9. *The vertical distribution Δ_v is integrable because $\Delta_v = \operatorname{Ker} T\pi$ and the vector fields* (15) *are infinitesimals of Δ_v. For any coframe θ^i of Δ_v there exists an integrating matrix B_j^i such that $B_j^i\theta^j = du^i$. Then $B_k^i\theta^k(Xj) = \delta_j^i$ is unit matrix and B_j^i is inverse to the matrix $\theta^i(X_j)$.*

Let us mention that from (8) we have the same situation $e^{-Ct}\omega(\frac{\partial}{\partial I}) = E$. This generalizes the known property of integrating factor for $n = 1$ (see [1, p. 60]).

Proposition 10. *The vector field P represented in natural and adapted frames as follows (see [5, p. 286])*

$$P = \xi^i \frac{\partial}{\partial u^i} + \lambda^\alpha \frac{\partial}{\partial u^\alpha} = \xi^i X_i + \mu^\alpha \frac{\partial}{\partial u^\alpha}, \qquad \mu^\alpha = \lambda^\alpha - \Gamma_i^\alpha \xi^i,$$

is an infinitesimal symmetry of horizontal distribution Δ_h if and only if either

$$X_i\lambda^\alpha - P\Gamma_i^\alpha - \Gamma_j^\alpha X_i\xi^j = 0 \tag{17}$$

or

$$X_i\mu^\alpha + \Gamma_{i\beta}^\alpha \mu^\beta + 2K_{ij}^\alpha \xi^j = 0. \tag{18}$$

For the case

$$\Gamma_i^\alpha = -\Gamma_{i\beta}^\alpha u^\beta, \qquad \mu^\alpha = \mu_\beta^\alpha u^\beta, \qquad \lambda^\alpha = \lambda_\beta^\alpha u^\beta, \qquad \mu_\beta^\alpha = \lambda_\beta^\alpha + \Gamma_{i\beta}^\alpha \xi^i$$

the conditions (17) and (18) are equivalent to

$$\partial_i\lambda_\beta^\alpha - \lambda_\gamma^\alpha\Gamma_{i\beta}^\gamma + \Gamma_{i\gamma}^\alpha\lambda_\beta^\gamma + \partial_i\Gamma_{j\beta}^\alpha\xi^j + \Gamma_{j\beta}^\alpha X_i\xi^j = 0, \tag{19}$$
$$\partial_i\mu_\beta^\alpha - \mu_\gamma^\alpha\Gamma_{i\beta}^\gamma + \Gamma_{i\gamma}^\alpha\mu_\beta^\gamma - 2K_{ij\beta}^\alpha\xi^j = 0. \tag{20}$$

On the tangent bundle $TM \longrightarrow M$ we have the correspondence

$$(u^i, u^\alpha) \sim (u^i, du^i), \qquad (\xi^i, \lambda^\alpha) \sim (\xi^i, d\xi^i), \qquad \lambda_\beta^\alpha \sim \frac{\partial \xi^i}{\partial u^j}, \qquad \mu^\alpha \sim \frac{\partial \xi^i}{\partial u^j} + \Gamma_{kj}^i \xi^k$$

and the conditions (19) and (20) define P as an *affine collineation* (infinitesimal movement in the space of affine connection or *Killing's vector field* in Riemannian geometry), see [6, p. 37, formulae (2.30) and (2.31)].

Remark 4. For ODE $y' + p(x)y + q(x) = 0$ we have $\omega = (py + q)dx + dy$ and the condition (18) gives $\mu = e^{-\int p dx}$. The form

$$\frac{\omega}{\mu} = d\left(\frac{y}{\mu}\right) + \frac{q}{\mu}dx$$

is exact and determines the first integral (see [1, p. 160])

$$\frac{y}{\mu} + \int \frac{q}{\mu}dx.$$

For the system of two-dimensional plasticity equations with the help of conservation laws basic boundary problems are solved. We have considered solutions of some concrete boundary problems. Using the symmetry transformations, from the well known Prandtle's solution we deduce some new solutions, describing the pressing of a layer between two rugged slabs. Also, some new properties of characteristics of the plane plasticity are shown.

1 Introduction

Among hyperbolic systems of nonlinear equations with partial derivatives the systems of the quasilinear equations of two independent variables are most investigated. These systems describe, in particular, unsteady one-dimensional and supersonic two-dimensional stationary flows of compressible gases and liquids, two-dimensional deformed plastic state of a continuous medium and so on. A lot of them are reduced to a hyperbolic system of homogeneous quasilinear equations

$$\begin{aligned} &u_x + A(u,v)u_y = 0,\\ &v_x + B(u,v)v_y = 0, \end{aligned} \tag{1}$$

where $u = u(x,y)$, $v = v(x,y)$, an indices below mean derivation with respect to the corresponding variables.

In the Section 2 we describe a method of the analytical solving of boundary-value problems for the system (1). This method is based on the conservations laws that allow us to consider linearization of problems without nonsingular transformations and to obtain exact solutions of boundary-value problems in explicit form. In the Section 3 we consider some concrete systems.

Other way to solve some boundary-value problems is using of symmetries of equations. The theory of symmetries is widely used in investigation and in resolution of differential equations. A group of symmetries allows to find exact solutions of differential equations and to classify PDE's by admitting groups.

Symmetries admitted by the system of PDE's have a great property: under its action any solutions of the system are transformed to the solutions of this system. This property allows to construct new solutions without integrating of the given system, only by means of group transformations of known solutions. In such a way some of interesting results were obtained [1]. Note that this way is effective only if we have a sufficiently rich group of point transformations. In the Section 4 Prandtl's solution was transformed. As a result we obtained a lot of exact solutions. We selected only restricted ones along Oy-axis ones and these solutions can be used for the solving of boundary-value problems for compression of a plastic layer by rigid parallel slabs. We can hope that with the help of these solutions it will be possible to describe not only compression of the thin layers, but the thick ones too.

2 Conservation laws

Let us set Cauchy's problem: in some neighborhood of an arc $a \le \tau \le b$ of a smooth curve

$$L = \{(x, y) : x = x(\tau), y = y(\tau), \tau \in [a, b]\}$$

in the plane xOy it is required to find a solution of the system (1) that takes given values on L

$$u(x, y)|_L = u(x(\tau), y(\tau)) = u^0(\tau), \qquad v(x, y)|_L = v(x(\tau), y(\tau)) = v^0(\tau).$$

The characteristics equations of the system (1) look like

$$\frac{dx}{dy} = A, \qquad \frac{dx}{dy} = B, \tag{2}$$

with the relations on the characteristics $u = u^0$, $v = v^0$ respectively.

We search a conservation law of the set of equations (1) in the form of a relation

$$C_x + D_y = 0, \tag{3}$$

where $C = C(u, v)$, $D = D(u, v)$, which should vanish only on the solutions of the system (1):

$$C_u u_x + C_v v_x + D_u u_y + D_v v_y = -AC_u u_y - BC_v v_y + D_u u_y + D_v v_y = 0,$$

hence

$$D_u - AC_u = 0, \qquad D_v - BC_v = 0. \tag{4}$$

The equation (3), if conditions of Green's theorem are satisfied, is equivalent to a relation

$$\oint_\Gamma -Cdy + Ddx = 0,$$

where Γ is an arbitrary closed contour.

In the plane xOy we will consider the closed path MNK, where $M(x_m(a), y_m(a))$, $N(x_n(b), y_n(b)) \in L$, $K(x_k, y_k)$ is the point of an intersection of characteristics $v = v^0$, $u = u^0$, drawn through the points M, N respectively.

Then,

$$\oint_{MNK} -Cdy + Ddx = \int_{MN} Ddx - Cdy + \int_{NK} Ddx - Cdy + \int_{KM} Ddx - Cdy = 0. \tag{5}$$

Taking into account the expressions (2)

$$\int_{NK} Ddx - Cdy = \int_{NK} (D - AC)dx = x(D - AC)\Big|_{x_n}^{x_k} - \int_{NK} x\partial_v(D - AC)dv.$$

Similarly,

$$\int_{KM} Ddx - Cdy = \int_{KM} (D - BC)dx = x(D - BC)\Big|_{x_k}^{x_m} - \int_{KM} x\partial_u(D - BC)du.$$

Let us assume

$$\partial_v \left[(D - AC)|_{u=u^0(x(b),y(b))}\right] = 0, \qquad \partial_u \left[(D - BC)|_{v=v^0(x(a),y(a))}\right] = 0. \tag{6}$$

Let us denote

$$\phi(u,v) = D - AC, \qquad \psi(u,v) = D - BC.$$

Then

$$D = (A\psi - B\phi)/(A-B), \qquad C = (\psi - \phi)/(A-B),$$

where $A \neq B$, because the considered system (1) is the hyperbolic one and has two different families of characteristics.

In the new variables, the system (4) has the form

$$\begin{aligned} &\phi_u + K_1(\psi - \phi) = 0, \\ &\psi_v + K_2(\psi - \phi) = 0, \end{aligned} \tag{7}$$

where $K_1 = A_u/(A-B)$, $K_2 = B_v/(A-B)$.

We will write the conditions (6) as follows

$$\phi|_{u=u^0} = \text{const}_1 = 1, \qquad \psi|_{v=v^0} = \text{const}_2 = 0. \tag{8}$$

Coming back to (5) and taking into account (8), we obtain

$$\begin{aligned} \int_{MN} Ddx - Cdy &= -(x(D-AC)|_{x_n}^{x_k} + x(D-BC)|_{x_k}^{x_m}) \\ &= -(x_k\phi|_{u=u^0,v=v^0} - x_n\phi|_{u=u^0} + x_m\psi|_{v=v^0} - x_k\psi|_{u=u^0,v=v^0}) = x_n - x_k. \end{aligned} \tag{9}$$

If we find a solution of the linear system (7) satisfying to the boundary conditions (8), then we will determine the coordinate x_k from the equation (9).

On the other hand, for y-coordinate

$$\int_{NK} Ddx - Cdy = \int_{NK} \left(\frac{D}{A} - C\right) dy = y\,\frac{\phi}{A}\Big|_{y_n}^{y_k} - \int_{NK} y\partial_v\left(\frac{\phi}{A}\right) dv.$$

Similarly,

$$\int_{KM} Ddx - Cdy = \int_{KM} \left(\frac{D}{B} - C\right) dy = y\,\frac{\psi}{B}\Big|_{y_k}^{y_m} - \int_{KM} y\partial_u\left(\frac{\psi}{B}\right) du.$$

Let us assume

$$\partial_v\left[\frac{\phi}{A}\Big|_{u=u^0(x(b),y(b))}\right] = 0, \qquad \partial_u\left[\frac{\psi}{B}\Big|_{v=v^0(x(a),y(a))}\right] = 0. \tag{10}$$

We can write the conditions (10) as follows

$$\phi|_{u=u^0} = A(u^0, v), \qquad \psi|_{v=v^0} = 0. \tag{11}$$

From (5), taking into account (10), we have

$$\begin{aligned} \int_{MN} Ddx - Cdy &= -y_k\,\frac{\phi}{A}\Big|_{u=u^0,v=v^0} + y_n\,\frac{\phi}{A}\Big|_{u=u^0} \\ &- y_m\,\frac{\psi}{B}\Big|_{v=v^0} + y_k\,\frac{\psi}{B}\Big|_{u=u^0,v=v^0} = y_n - y_k. \end{aligned} \tag{12}$$

The solution of the problem (7), (11) makes possible to find the coordinate y_k from the equation (12). Thus, we will determine the coordinates of the point K, where the values of the functions u, v can be reconstructed.

3 Examples of application of the method

1. In the work [2] the solution was found that takes given values on L

$$\sigma(x,y)|_L = \sigma_0, \qquad \theta(x,y)|_L = \theta_0$$

for the initial problem for the system of 2-dimensional plasticity under von Mises condition

$$\begin{aligned} &\sigma_x - 2k\,(\theta_x \cos 2\theta + \theta_y \sin 2\theta) = 0,\\ &\sigma_y - 2k\,(\theta_x \sin 2\theta - \theta_y \cos 2\theta) = 0, \end{aligned} \tag{13}$$

where σ is a hydrostatic pressure, θ is an angle between the first main direction of a stress tensor and the ox-axis, k is a constant of plasticity. This system in the form (1) is

$$\xi_x + \xi_y \tan\theta = 0, \qquad \eta_x - \eta_y \cot\theta = 0,$$

where $2\theta = \eta - \xi$, $\sigma = k(\eta + \xi)$. Solution of problem (7), (8) has the form: $\phi = \rho/\cos\theta$, $\psi = 2\rho_\xi/\sin\theta$, where

$$\rho(\xi,\eta) = R(\xi,\xi_0,\eta,\eta_0)\cos\left(\frac{\eta_0-\xi_0}{2}\right) - \frac{1}{2}\int_{\eta_0}^{\eta} R(\xi,\xi_0,\eta,\tau)\sin\left(\frac{\tau-\xi_0}{2}\right)\,d\tau.$$

Accordingly, the solution of the problem (7), (11) is

$$\rho(\xi,\eta) = R(\xi,\xi_0,\eta,\eta_0)\sin\left(\frac{\eta_0-\xi_0}{2}\right) + \frac{1}{2}\int_{\eta_0}^{\eta} R(\xi,\xi_0,\eta,\tau)\cos\left(\frac{\tau-\xi_0}{2}\right)\,d\tau,$$

where $R(\xi,\eta,\xi_0,\eta_0) = I_0\left(\sqrt{(\xi-\xi_0)(\eta-\eta_0)}\right)$ is Bessel function of a zero order of imaginary argument, $I_0(0) = 1$, $I_0'(0) = 0$.

2. The generalization of (13) is a system of ideal plasticity equations under Coulomb's plasticity condition that has the form:

$$\begin{aligned} &\sigma_x(1+\cos 2\alpha\cos 2\Theta) + \sigma_y \cos 2\alpha \sin 2\Theta = 2(\sigma\cos 2\alpha + k\sin 2\alpha)(\Theta_x \sin 2\Theta - \Theta_y \cos 2\Theta),\\ &\sigma_x \cos 2\alpha \sin 2\Theta + \sigma_y(1-\cos 2\alpha\cos 2\Theta) = -2(\sigma\cos 2\alpha + k\sin 2\alpha)(\Theta_x\cos 2\Theta + \Theta_y \sin 2\Theta), \end{aligned}$$

where $\pi/2 - 2\alpha$ is a constant angle of internal friction, $\Theta = \theta + \pi/4$. If $\alpha = \pi/4$, then we have the system (13). This system in the form (1) is:

$$\xi_x + \xi_y \tan(\Theta - \alpha) = 0, \qquad \eta_x - \eta_y \tan(\Theta+\alpha) = 0,$$

where $\xi = \frac{1}{2}\tan 2\alpha \ln(\sigma\cot 2\alpha + k) - \Theta$, $\eta = \frac{1}{2}\tan 2\alpha \ln(\sigma\cot 2\alpha + k) + \Theta$. Solution of problem (7), (8) has a form [3]: $\phi = \gamma(-\xi,-\eta)V(\xi,\eta)/\cos(\Theta-\alpha)$, $\gamma(\xi,\eta) = \exp(-(\xi+\eta)/2\cot 2\alpha)$, where:

$$\begin{aligned} V = {}& \gamma(\xi_0,\eta_0)R(\xi,\xi_0,\eta,\eta_0)\cos\left((\eta_0-\xi_0)/2-\alpha\right)\\ &- \frac{1}{2}\int_{\eta_0}^{\eta} R(\xi,\xi_0,\eta,\tau)\gamma(\xi_0,\tau)\left[\sin\left((\tau-\xi_0)/2-\alpha\right) - \cot 2\alpha\cos\left((\tau-\xi_0)/2-\alpha\right)\right]\,d\tau. \end{aligned} \tag{14}$$

The solution of the problem (7), (11) is

$$\begin{aligned} V = {}& \gamma(\xi_0,\eta_0)R(\xi,\xi_0,\eta,\eta_0)\sin\left((\eta_0-\xi_0)/2-\alpha\right)\\ &- \frac{1}{2}\int_{\eta_0}^{\eta} R(\xi,\xi_0,\eta,\tau)\gamma(\xi_0,\tau)\left[\cot 2\alpha\sin\left((\tau-\xi_0)/2-\alpha\right) - \cos\left((\tau-\xi_0)/2-\alpha\right)\right]\,d\tau, \end{aligned} \tag{15}$$

$R(\xi,\eta,\xi_0,\eta_0) = I_0\left(\sqrt{(\xi-\xi_0)(\eta-\eta_0)}/\sin 2\alpha\right)$. From the equation (9) taking into account (14) we will find a coordinate x_k. Using (15), from the equations (12) we will obtain a coordinate y_k. Thus, we have determined a point K, in which the values of functions ξ, η are reconstructed.

4 Reproduction of Prandle's solution

Let us consider the system (13) that has two families of characteristics (in the theory of plasticity they are named slide lines) with the following equations and relations along characteristics:

$$\frac{dy}{dx} = \tan\theta, \qquad \frac{\sigma}{2k} - \theta = c_1,$$
$$\frac{dy}{dx} = -\cot\theta, \qquad \frac{\sigma}{2k} + \theta = c_2.$$

This system admits the infinite group of symmetries [4]. Its point subgroup is generated by following generators:

$$X_1 = \partial_x, \qquad X_2 = \partial_y, \qquad X_3 = x\partial_x + y\partial_y, \qquad X_4 = -x\partial_y + y\partial_x + \partial_\theta,$$
$$X_5 = \partial_\sigma, \qquad X_6 = \xi_1\partial_x + \xi_2\partial_y + 4k\theta\partial_\sigma - \frac{\sigma}{k}\partial_\theta, \qquad X = \xi\partial_x + \eta\partial_y, \tag{16}$$

where

$$\xi_1 = -x\cos 2\theta - y\sin 2\theta - y\frac{\sigma}{k}, \qquad \xi_2 = y\cos 2\theta - x\sin 2\theta + x\frac{\sigma}{k},$$

and (ξ, η) is an arbitrary solution of the following lineal system of equations:

$$\xi_\theta - 2k\left(\xi_\sigma\cos 2\theta + \eta_\sigma\sin 2\theta\right) = 0,$$
$$\eta_\theta - 2k\left(\xi_\sigma\sin 2\theta - \eta_\sigma\cos 2\theta\right) = 0, \tag{17}$$

Transformations, which correspond to any generator of (16), convert the system (13) to itself. Thus, for the generator X we have transformations of independent variables:

$$x' = x + a\xi, \qquad y' = y + a\eta, \tag{18}$$

where a is an arbitrary parameter, (ξ, η) is an arbitrary solution of (17). As X is an admitted generator, the transformations (18) do not change the form of the system (13). Note that we have shown the variables that are changed under this transformation, other variables are omitted.

Under the action of the symmetry group, any solution of the system (13) is transformed to the solution of this system. Furthermore, it is easy to demonstrate

Proposition 1. *The characteristics of the system* (13) *are transformed to the characteristics of this system under the action of symmetry group* (16).

The system (13) is being investigated for more than 100 years, but there are a few of its exact solutions. Certainly, one of the well-known solutions was constructed by Prandtl [5]. Let us write this solution in the form

$$\sigma = -kx + k\left(1 - y^2\right)^{\frac{1}{2}}, \qquad 2\theta = \arccos y. \tag{19}$$

From proposition, in particular, it is follows that for the construction of slide lines we should substitute the characteristic relations to the solution. Let us substitute the relation along the first characteristic $\sigma/(2k) - \theta = c_1$ to the solution (19). We obtain the equation of the first family of slide lines:

$$x = -2\theta + \sin 2\theta + K_1, \qquad y = \cos 2\theta.$$

By analogy, we obtain the second family of slide lines with relation $\sigma/(2k) + \theta = c_2$:

$$x = 2\theta + \sin 2\theta + K_2, \; y = \cos 2\theta.$$

Under the transformations (18), Prandtl's solution will transform to the following one:

$$\sigma = -kx + ak\xi + k\sin 2\theta, \qquad y = \cos 2\theta + a\eta, \tag{20}$$

and the slide lines will have the form:

$$x = \mp 2\theta + a\xi + \sin 2\theta + K_i, \qquad y = \cos 2\theta + a\eta, \qquad i = 1, 2.$$

Therefore, in order to obtain new solutions, we have to find some solutions of the system (17). This is the system of PDE's of the first order with the variable coefficients, and it is possible to find solutions in the form of series:

$$\xi = \sum_{i=1}^{\infty} \left[f_i(\sigma)\cos(i\theta) + g_i(\sigma)\sin(i\theta) \right], \qquad \eta = \sum_{i=1}^{\infty} \left[F_i(\sigma)\cos(i\theta) + G_i(\sigma)\sin(i\theta) \right],$$

where $f_i(\sigma)$, $g_i(\sigma)$, $F_i(\sigma)$, $G_i(\sigma)$ are the functions, obtained as solutions of a system of ODE's. This way can be successful, but it is difficult to give an analysis of results and use them for practical goals. Therefore, we can find some solutions of (17) in a simpler way, which can be used in practice. Solutions of the system (17) we can find in the forms:

$$\xi = \alpha\sigma + F(\theta), \qquad \eta = \beta\sigma + G(\theta), \tag{21}$$

$$\xi = f(\theta)\exp\left(\frac{\sigma}{2k}\right), \qquad \eta = g(\theta)\exp\left(\frac{\sigma}{2k}\right), \tag{22}$$

$$\xi = \alpha(\theta)\sin\frac{\sigma}{2k} + \beta(\theta)\cos\frac{\sigma}{2k}, \qquad \eta = F(\theta)\sin\frac{\sigma}{2k} + G(\theta)\cos\frac{\sigma}{2k}, \tag{23}$$

$$\xi = \alpha(\theta)\sinh\frac{\sigma}{2k} + \beta(\theta)\cosh\frac{\sigma}{2k}, \qquad \eta = F(\theta)\sinh\frac{\sigma}{2k} + G(\theta)\cosh\frac{\sigma}{2k}, \tag{24}$$

where functions f, g, α, β, F, G are determined as a solution of corresponding systems of ODEs.

It is easy to see that under the transformation (21) the Prandtl's solutions is transformed into the solution of the same form (there is no new solution).

Under the transformations (22), (24) the solution will be transformed to the non-restricted ones along the *oy*-axis, hence we do not consider solutions of this form in this article.

Let us consider the action of ultimate transformation (23) to the slide lines. Substituting (23) to the system (17) we have the system of equations for a determination of functions α, β, F, G

$$\begin{aligned} &\alpha' + \beta\cos 2\theta + G\sin 2\theta = 0, \qquad \beta' - \alpha\cos 2\theta - F\sin 2\theta = 0, \\ &F' + \beta\sin 2\theta - G\cos 2\theta = 0, \qquad G' - \alpha\sin 2\theta + F\cos 2\theta = 0. \end{aligned} \tag{25}$$

Let us derive each of the equations (25) with respect to θ. Then, according to (25), we obtain the equations:

$$\begin{aligned} &\alpha'' + \alpha + 2F' = 0, \qquad F'' + F - 2\alpha' = 0, \\ &\beta'' + \beta + 2G' = 0, \qquad G'' + G - 2\beta' = 0, \end{aligned} \tag{26}$$

Let us find the solution of the first system of (26) in the form

$$\alpha = Ce^{\lambda\theta}, \qquad F = De^{\lambda\theta}, \qquad C, D = \text{const}.$$

Therefore, for the determination of λ, C, D we have the algebraic equations

$$C\lambda^2 + C + 2D\lambda = 0, \qquad D\lambda^2 + D - 2C\lambda = 0.$$

Hence $C = \pm iD$, $\lambda_{1,2} = i(1 \pm \sqrt{2})$, $i^2 = -1$. Then, a real solution for α, F has the form

$$\alpha = C_1 \cos\left(1 \pm \sqrt{2}\right)\theta - C_2 \sin\left(1 \pm \sqrt{2}\right)\theta,$$
$$F = C_1 \sin\left(1 \pm \sqrt{2}\right)\theta + C_2 \cos\left(1 \pm \sqrt{2}\right)\theta,$$

where C_1, C_2 are arbitrary constants.

Then, solution for β, G of the second system (26), according to (25) will take the form:

$$\beta = \left(1 \pm \sqrt{2}\right)\left(C_2 \cos\left(1 \mp \sqrt{2}\right)\theta - C_1 \sin\left(1 \mp \sqrt{2}\right)\theta\right),$$
$$G = \left(1 \pm \sqrt{2}\right)\left(C_2 \sin\left(1 \mp \sqrt{2}\right)\theta + C_1 \cos\left(1 \mp \sqrt{2}\right)\theta\right)$$

For a simplicity let us $C_2 = 0$, and let us take the lower sign, then (23) we can write down in the form:

$$\xi = \cos\left(1 - \sqrt{2}\right)\theta \sin\frac{\sigma}{2k} - \left(1 - \sqrt{2}\right)\sin\left(1 + \sqrt{2}\right)\theta \cos\frac{\sigma}{2k},$$
$$\eta = \sin\left(1 - \sqrt{2}\right)\theta \sin\frac{\sigma}{2k} + \left(1 - \sqrt{2}\right)\cos\left(1 + \sqrt{2}\right)\theta \cos\frac{\sigma}{2k}.$$

The transformations of the slide lines can be written as:

$$x = \mp 2\theta + a\left[\cos\left(1 - \sqrt{2}\right)\theta \sin(\pm\theta + c_i) - \left(1 - \sqrt{2}\right)\sin\left(1 + \sqrt{2}\right)\theta \cos(\pm\theta + c_i)\right]$$
$$+ \sin 2\theta + K_i, \qquad i = 1, 2,$$
$$y = \cos 2\theta + a\left[\sin\left(1 - \sqrt{2}\right)\theta \sin(\pm\theta + c_i) + \left(1 - \sqrt{2}\right)\cos\left(1 + \sqrt{2}\right)\theta \cos(\pm\theta + c_i)\right]. \quad (27)$$

From relations (27) it follows, that new solution has restricted slide lines, and we can use these solutions for description of plastic flows between two rugged slabs.

With the increment of parameter a the thickness of layer increases and becomes approximately equal to $2(h + a)$, where h is a thickness of the initial layer. The new solution that we named S-solution, i.e. obtained from the Prandtl's solution by means of symmetry transformations (20), has the form:

$$\sigma = -kx + a\left[\cos\left(1 - \sqrt{2}\right)\theta \sin\frac{\sigma}{2k} - \left(1 - \sqrt{2}\right)\sin\left(1 + \sqrt{2}\right)\theta \cos\frac{\sigma}{2k}\right] + k\left(1 - y^2\right)^{\frac{1}{2}},$$
$$y = \cos 2\theta + a\left[\sin\left(1 - \sqrt{2}\right)\theta \sin\frac{\sigma}{2k} + \left(1 - \sqrt{2}\right)\cos\left(1 + \sqrt{2}\right)\theta \cos\frac{\sigma}{2k}\right],$$

where a is an arbitrary parameter. For large values of parameter a we have S-solution far different from Prandle's solution. It can be used for analysis of not thin plastic flows.

E-mail: *Artur.Sergyeyev@math.slu.cz*

We derive a formula for the leading terms of formal conservation laws (and hence for the leading terms of higher order cosymmetries as well) for a large class of odd order evolution systems in (1+1)-dimensions. This result yields a simple proof of locality for hierarchies of symmetries generated using master symmetries and recursion operators of such systems.

Introduction

It is well known that members of integrable hierarchies of systems of partial differential equations (PDEs) usually have an infinite number of common conservation laws, see e.g. [1–4]. The latter are typically extracted from the Lax pair or zero curvature representation for the system in question, cf. e.g. [4].

On the other hand, one often has to deal with the inverse problem, that is, to check whether a given conserved density or, more broadly, a cosymmetry [1] (in other terminology, a conserved covariant [5]) is indeed shared by the evolution systems associated with the symmetries of the original system. For instance, we may need to verify whether a given physical quantity (charge, momentum, etc.) is invariant under the higher flows of the hierarchy. This is also required when we wish to verify locality of the hierarchy of symmetries produced by the repeated application of a recursion operator or by the repeated commutation with a master symmetry, cf. [2, 3, 6–11].

Checks of this kind can be quite a difficult task, especially when no Lax pair or zero curvature representation for the system in question is yet found. A possible workaround is to use scaling-based arguments, see e.g. [12], but then one has to know the weights of all (homogeneous) cosymmetries for the system in question. Finding these weights is a fairly nontrivial problem, and in the present paper we solve it for the odd order evolution systems in (1+1) dimensions.

First of all, we derive, under some minor technical assumptions, an explicit formula (8) for the leading terms of formal conservation laws for such systems, see Lemma 1 for details. As the directional derivative of a cosymmetry is a formal conservation law, this yields the formula (10) for the weight of any homogeneous cosymmetry of sufficiently high order.

With this in mind, we can find when a homogeneous cosymmetry is shared by the flow associated with a given (homogeneous) symmetry, i.e., when the Lie derivative of this cosymmetry along the symmetry in question vanishes, see Lemma 2 below for details. Using this result, we obtain new easily verifiable sufficient conditions ensuring the locality of symmetries generated with usage of recursion operator or master symmetry, see Propositions 1 and 3 and Corollaries 1 and 2.

For the hierarchies generated using hereditary recursion operators one can [7, 8, 10] prove locality without finding weights of all cosymmetries. Unfortunately, the check of hereditariness can be quite difficult by itself, especially for the multicomponent systems. Proposition 1 and

[1] On leave from Silesian University in Opava, Mathematical Institute, Na Rybníčku 1, 746 01 Opava, Czech Republic.

Corollary 1 of the present work enable one to avoid this check altogether and prove the locality of corresponding hierarchy in a simple and straightforward manner.

The absence of immediate analog of hereditariness for master symmetries makes the technique of [7,8] useless for proving locality of the associated hierarchies. If the only nonlocalities in master symmetries are linear combinations of potentials of the so-called canonical conservation laws, we can prove locality of generated symmetries using the results from [11]. However, if master symmetries involve other nonlocalities as well, one needs other methods for proving locality of symmetries, and the one presented below in Proposition 3 and Corollary 2 provides a convenient and easy-to-use alternative.

1 Basic definitions and structures

Consider an evolution system with constraints (cf. [13–15])

$$\frac{\partial \boldsymbol{u}}{\partial t} = \boldsymbol{F}(x,t,\boldsymbol{u},\boldsymbol{u}_1,\dots,\boldsymbol{u}_{n'},\vec{\omega}), \tag{1}$$

$$\partial\omega_\kappa/\partial x = X_\kappa(x,t,\boldsymbol{u},\boldsymbol{u}_1,\dots,\boldsymbol{u}_h,\vec{\omega}), \tag{2}$$

$$\partial\omega_\kappa/\partial t = T_\kappa(x,t,\boldsymbol{u},\boldsymbol{u}_1,\dots,\boldsymbol{u}_h,\vec{\omega}). \tag{3}$$

Here $\boldsymbol{u} = (u^1,\dots,u^s)^T$, $\boldsymbol{u}_0 \equiv \boldsymbol{u}$, $\boldsymbol{u}_l = \partial^l\boldsymbol{u}/\partial x^l$, $l = 1,2,\dots$, $\vec{\omega} = (\omega_1,\dots,\omega_c)^T$, $\kappa = 1,\dots,c$. The superscript T here and below stands for the matrix transposition.

Let $\mathcal{A}_j$ be an algebra (with respect to the standard multiplication) of locally analytic functions of $x,t,\boldsymbol{u},\dots,\boldsymbol{u}_j,\omega_1,\dots,\omega_c$, cf. [13]. Set $\mathcal{A} = \bigcup_{j=1}^\infty \mathcal{A}_j$. In what follows we assume that X_κ, $T_\kappa \in \mathcal{A}$ for all $\kappa = 1,\dots,c$.

Let $D_x \equiv D = \partial/\partial x + \sum\limits_{i=0}^{\infty} \boldsymbol{u}_{i+1}\partial/\partial\boldsymbol{u}_i + \sum\limits_{\kappa=1}^{c} X_\kappa\partial/\partial\omega_\kappa$ and $D_t = \partial/\partial t + \sum\limits_{i=0}^{\infty} D^i(\boldsymbol{F})\partial/\partial\boldsymbol{u}_i + \sum\limits_{\kappa=1}^{c} T_\kappa\partial/\partial\omega_\kappa$ be the operators of total derivatives on $\mathcal{A}$, cf. [13–15].

As in [13–15], we require that $[D,D_t] = 0$ or, equivalently, $D_t(X_\kappa) = D(T_\kappa)$ for all $\kappa = 1,\dots,c$. In what follows we tacitly assume that the kernel of D in $\mathcal{A}$ is exhausted by the functions of t alone. We shall employ the notation $\operatorname{Im} D$ for the image of D in $\mathcal{A}$.

Consider the set $\operatorname{Mat}_p(\mathcal{A})[\![D^{-1}]\!]$ of *formal series* in powers of D of the form $\mathfrak{H} = \sum\limits_{j=-\infty}^{q} h_j D^j$, where h_j are $p\times p$ matrices with entries from $\mathcal{A}$. The greatest $m\in\mathbb{Z}$ such that $h_m \neq 0$ is called the *degree* of $\mathfrak{H}$ ($\deg\mathfrak{H} \stackrel{\text{def}}{=} m$). If $\det h_m \neq 0$, then $\mathfrak{H}$ is called *nondegenerate*. We assume that $\deg 0 = -\infty$, cf. e.g. [2].

For $\mathfrak{A} = \sum\limits_{i=-\infty}^{k} a_i D^i$ define [16,2] its formal adjoint $\mathfrak{A}^\dagger \stackrel{\text{def}}{=} \sum\limits_{i=-\infty}^{k} (-D)^i \circ a_i^T$. Here $\circ$ stands for the multiplication generalizing the well-known Leibniz rule of calculus. For monomials it reads

$$aD^i \circ bD^j = a\sum_{q=0}^{\infty} \frac{i(i-1)\cdots(i-q+1)}{q!} D^q(b) D^{i+j-q}.$$

It is extended by linearity to the whole $\operatorname{Mat}_p(\mathcal{A})[\![D^{-1}]\!]$ and makes it into an algebra [2,16]. The commutator $[\mathfrak{A},\mathfrak{B}] = \mathfrak{A}\circ\mathfrak{B} - \mathfrak{B}\circ\mathfrak{A}$ further makes $\operatorname{Mat}_p(\mathcal{A})[\![D^{-1}]\!]$ into a Lie algebra. In the sequel we shall omit $\circ$ unless this leads to confusion.

The directional derivative $\vec{f}'$ of $\vec{f}\in\mathcal{A}^q$ is defined as (cf. [13])

$$\vec{f}' = \sum_{\beta,\kappa=1}^{c} \frac{\partial\vec{f}}{\partial\omega_\beta}\big((D-W)^{-1}\big)_{\beta\kappa} \circ \sum_{j=0}^{h} \partial X_\kappa/\partial\boldsymbol{u}_j \circ D^j + \sum_{i=0}^{\infty} \frac{\partial\vec{f}}{\partial\boldsymbol{u}_i} D^i.$$

Here W is a $c\times c$ matrix with the entries $\partial X_\alpha/\partial\omega_\beta$, and $(D-W)^{-1}=D^{-1}\circ\left(\mathbb{I}-W\circ D^{-1}\right)^{-1}=\mathbb{I}D^{-1}+D^{-1}\circ W\circ D^{-1}+\cdots\equiv\mathbb{I}D^{-1}+\sum\limits_{j=-\infty}^{-2}W_jD^j$, where W_j are $c\times c$ matrices with entries from $\mathcal{A}$ and $\mathbb{I}$ denotes a $c\times c$ unit matrix. In other words, for the entries of $(D-W)^{-1}$ we have

$$((D-W)^{-1})_{\alpha\beta}\equiv\delta_{\alpha\beta}D^{-1}+\sum_{j=-\infty}^{-2}(W_j)_{\alpha\beta}D^j,$$

where $(W_j)_{\alpha\beta}$ is the (α,β)-th entry of the matrix W_j, and $\delta_{\alpha\beta}$ is Kronecker delta.

Clearly, for $\boldsymbol{K}\in\mathcal{A}^s$ we have $\boldsymbol{K}'\in\mathrm{Mat}_s(\mathcal{A})[\![D^{-1}]\!]$, so we can define the *formal order* of $\boldsymbol{G}\in\mathcal{A}^s$ as $\mathrm{ford}\,\boldsymbol{G}\stackrel{\mathrm{def}}{=}\deg\boldsymbol{G}'$.

Next, define [1,2] the *Lie bracket* for $\boldsymbol{K},\boldsymbol{H}\in\mathcal{A}^s$ as $[\boldsymbol{K},\boldsymbol{H}]=\boldsymbol{H}'[\boldsymbol{K}]-\boldsymbol{K}'[\boldsymbol{H}]$. It is skew-symmetric, but in general for $\boldsymbol{K},\boldsymbol{H}\in\mathcal{A}^s$ the Lie bracket $[\boldsymbol{K},\boldsymbol{H}]$ is not obliged to belong to $\mathcal{A}^s$ unless $\mathcal{A}=\mathcal{A}_{\mathrm{loc}}$, where $\mathcal{A}_{\mathrm{loc}}$ is a subalgebra of *local* (that is, independent of $\vec{\omega}$) functions in $\mathcal{A}$. Note that the restriction of the Lie bracket $[\cdot,\cdot]$ to $\mathcal{A}^s_{\mathrm{loc}}$ satisfies the Jacobi identity, see e.g. [2].

Following [1,2], we say that $\boldsymbol{G}\in\mathcal{A}^s$ is a *symmetry* for (1)–(3), if

$$\partial\boldsymbol{G}/\partial t+[\boldsymbol{F},\boldsymbol{G}]=0,\tag{4}$$

or equivalently [14]

$$D_t(\boldsymbol{G})-\boldsymbol{F}'[\boldsymbol{G}]=0.$$

Let $S_F^{(k)}(\mathcal{A})=\{\boldsymbol{G}\in\mathcal{A}^s|\frac{\partial\boldsymbol{G}}{\partial t}+[\boldsymbol{F},\boldsymbol{G}]=0\text{ and }\mathrm{ford}\boldsymbol{G}\le k\}$, $S_F(\mathcal{A})=\bigcup_{j=0}^\infty S_F^{(j)}(\mathcal{A})$, $\mathrm{Ann}_F(\mathcal{A})=\{\boldsymbol{G}\in S_F(\mathcal{A})|\partial\boldsymbol{G}/\partial t=0\}$, and $\boldsymbol{F}'\equiv\sum\limits_{i=-\infty}^{n}\phi_iD^i$, where $n=\mathrm{ford}\,\boldsymbol{F}$. Set

$$n_0=\begin{cases}1-j,\text{ if }\phi_i'=0\text{ for }i=n-j,\dots,n,\\ 2\text{ otherwise.}\end{cases}$$

A *formal conservation law* of rank m for (1)–(3) is [16,2] a formal series $\mathfrak{L}\in\mathrm{Mat}_s(\mathcal{A})[\![D^{-1}]\!]$ such that

$$\deg(D_t(\mathfrak{L})+\mathfrak{L}\circ\boldsymbol{F}'+(\boldsymbol{F}')^\dagger\circ\mathfrak{L})\le\deg\boldsymbol{F}'+\deg\mathfrak{L}-m.\tag{5}$$

Likewise, a *formal symmetry* of rank m for (1)–(3) is [16,2] a formal series $\mathfrak{L}\in\mathrm{Mat}_s(\mathcal{A})[\![D^{-1}]\!]$ such that

$$\deg(D_t(\mathfrak{L})-[\boldsymbol{F}',\mathfrak{L}])\le\deg\boldsymbol{F}'+\deg\mathfrak{L}-m.\tag{6}$$

Recall [5,1] that $\boldsymbol{\gamma}\in\mathcal{A}^s$ is called a *cosymmetry* (or a *conserved covariant*) for (1)–(3) if

$$D_t(\boldsymbol{\gamma})+(\boldsymbol{F}')^\dagger(\boldsymbol{\gamma})=0.\tag{7}$$

Set $CS_F(\mathcal{A})=\{\boldsymbol{\gamma}\in\mathcal{A}^s|D_t(\boldsymbol{\gamma})+(\boldsymbol{F}')^\dagger(\boldsymbol{\gamma})=0\}$ and $SCS_F(\mathcal{A})=\{\boldsymbol{\gamma}\in CS_F(\mathcal{A})|\partial\boldsymbol{\gamma}/\partial t=0\}$.

If $\mathrm{ford}\boldsymbol{\gamma}\equiv\deg\boldsymbol{\gamma}'=r\ge n_0$, then $\boldsymbol{\gamma}'$ is easily seen to be a formal conservation law of rank $r-n_0+2$. Likewise, if $\boldsymbol{G}$ is a symmetry of (1)–(3) of formal order $k\ge n_0$, then $\boldsymbol{G}'$ is a formal symmetry of rank $k-n_0+2$, cf. [16,17].

Define (see e.g. [2,3]) the operator of variational derivative

$$\delta/\delta\boldsymbol{u}=\sum_{j=0}^\infty(-D)^j\frac{\partial}{\partial\boldsymbol{u}_j}.$$

If $\rho\in\mathcal{A}_{\mathrm{loc}}$ is a conserved density for (1)–(3), that is, $D_t(\rho)=D(\sigma)$ for some $\sigma\in\mathcal{A}_{\mathrm{loc}}$, then $\boldsymbol{\gamma}=\delta\rho/\delta\boldsymbol{u}$ is a cosymmetry for (1)–(3), cf. e.g. [5,16].

2 NWD systems

Let Φ denote the leading coefficient of $\boldsymbol{F}'$ (so $\boldsymbol{F}' \equiv \Phi D^n + \cdots$). Suppose that $n = \deg \boldsymbol{F}' \geq 2$ and Φ is diagonalizable, i.e., there exists a matrix Γ such that $\Lambda = \Gamma\Phi\Gamma^{-1}$ is diagonal, $\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_s)$. Further assume that $\det \Phi \neq 0$ and $\lambda_i \neq \lambda_j$ if $i \neq j$. Following [17], we shall call the systems (1)–(3) that enjoy these properties *nondegenerate weakly diagonalizable (NWD)*, because for such systems there exists [16, 17] a unique formal series

$$\mathfrak{T} = \Gamma + \sum_{j=-1}^{-\infty} \Gamma_j \Gamma D^j \in \operatorname{Mat}_s(\mathcal{A})[\![D^{-1}]\!]$$

with the property $\operatorname{diag} \Gamma_j = 0$, $j = -1, -2, \ldots$, such that all coefficients of the formal series $\mathfrak{V} = \mathfrak{T}\boldsymbol{F}'\mathfrak{T}^{-1} + D_t(\mathfrak{T})\mathfrak{T}^{-1}$ are diagonal matrices. Notice that any system (1)–(3) with $s = 1$ is (trivially) NWD with $\mathfrak{T} = 1$.

We have $\mathfrak{V} \equiv \Lambda D^n + \Psi D^{n-1} + \cdots$, where Ψ is a diagonal matrix by construction, so $\Psi \equiv \operatorname{diag}(\psi_1, \ldots, \psi_s)$, $\psi_i \in \mathcal{A}$. For i such that $\psi_i/\lambda_i \in \operatorname{Im} D$ let $z_i \in \mathcal{A}$ be solutions of the equations $D(z_i) = \psi_i/\lambda_i$.

Lemma 1. *Let (1)–(3) be an NWD system with odd $n \equiv \deg \boldsymbol{F}' \geq 3$. Then any its formal conservation law $\mathfrak{L}$ of degree k and of rank $m \geq 2$ can be written in the form*

$$\mathfrak{L} = \mathfrak{T}^\dagger \circ (b_k \Lambda^{k/n} D^k + d_k D^{k-1}) \circ \mathfrak{T} + \mathfrak{N}, \qquad \deg \mathfrak{N} < k - 1. \tag{8}$$

Here $\Lambda^{k/n} = \operatorname{diag}(\lambda_1^{k/n}, \ldots, \lambda_s^{k/n})$, $b_k = \operatorname{diag}(c_1(t)\exp(2z_1/n), \ldots, c_s(t)\exp(2z_s/n))$, d_k is a diagonal $s \times s$ matrix; $c_i(t) = 0$ if $\psi_i/\lambda_i \notin \operatorname{Im} D$.

Proof. Set $\tilde{\mathfrak{L}} = (\mathfrak{T}^\dagger)^{-1} \circ \mathfrak{L} \circ \mathfrak{T}^{-1}$. Then equation (5) is [16] equivalent to the following:

$$\deg(D_t(\tilde{\mathfrak{L}}) + \tilde{\mathfrak{L}} \circ \mathfrak{V} + \mathfrak{V}^\dagger \circ \tilde{\mathfrak{L}}) \leq \deg \boldsymbol{F}' + \deg \tilde{\mathfrak{L}} - m. \tag{9}$$

Let $\tilde{\mathfrak{L}} \equiv L_k D^k + L_{k-1} D^{k-1} + \cdots$. Then equating to zero the coefficient at D^{n+k} in (9) yields $[L_k, \Lambda] = 0$, hence L_k is diagonal: $L_k = \operatorname{diag}(h_1, \ldots, h_s)$.

Diagonal entries of the matrix $[L_{k-1}, \Lambda]$ are zeros, so equating to zero the diagonal part of the coefficient at D^{m+k-1} in (9) yields

$$kh_i D(\lambda_i) - n\lambda_i D(h_i) + 2h_i\psi_i = 0, \qquad i = 1, \ldots, s.$$

Solving these equations yields $h_i = c_i(t)\lambda_i^{k/n}\exp(2z_i/n)$, where c_i are arbitrary functions of t; if $\psi_i/\lambda_i \notin \operatorname{Im} D$ for some i, then we have $c_i = 0$ for these values of i.

Finally, equating to zero the antidiagonal part of the coefficient at D^{m+k-1} in (9) yields $[L_{k-1}, \Lambda] = 0$, so L_{k-1} is a diagonal matrix. ■

Notice that using (8) for $\mathfrak{L} = \boldsymbol{\gamma}'$ one can readily find the form of leading terms for cosymmetries $\boldsymbol{\gamma}$ of formal order $q \geq n_0$. This complements known results (cf. e.g. [16, 18, 19]) and can be very useful e.g. while searching for cosymmetries and conserved densities for (1)–(3).

Remark 1. If $\psi_i/\lambda_i \notin \operatorname{Im} D$ for all $i = 1, \ldots, s$, then the system (1)–(3) has no formal conservation laws from $\operatorname{Mat}_s(\mathcal{A})[\![D^{-1}]\!]$ of rank $m \geq 2$ [16]. However, if (1)–(3) has a nondegenerate formal symmetry of rank not lower than $n + 2$, then [16] $\chi_i \equiv \psi_i/\lambda_i$ satisfy $D_t(\chi_i) = D(\xi_i)$, where $\xi_i \in \mathcal{A}$, for all $i = 1, \ldots, c$, and we can proceed as follows.

Let I_0 be the set of all $i \in \{1, \ldots, c\}$ such that $\chi_i \notin \operatorname{Im} D$. Next, let I be a maximal subset of I_0 such that χ_i for $i \in I$ are linearly independent. Introduce additional nonlocal variables $\tilde{\omega}_i$, $i \in I$, such that $\partial\tilde{\omega}_i/\partial t = \xi_i$ and $\partial\tilde{\omega}_i/\partial x = \chi_i$. Then $\chi_i \in \operatorname{Im} D$, as $\chi_i = D(\tilde{\omega}_i)$, so we can set $z_i = \tilde{\omega}_i$, and moreover [20], $\ker D$ is still exhausted by functions of t, so Lemma 1 remains valid in this extended setting.

3 Homogeneous cosymmetries of NWD systems

Following the literature (cf. e.g. [5,1,7]), define the Lie derivatives along $\boldsymbol{G} \in \mathcal{A}^s$ by the following formulae: a) $L_{\boldsymbol{G}}(f) = f'[\boldsymbol{G}]$ for $f \in \mathcal{A}$, b) $L_{\boldsymbol{G}}(\boldsymbol{H}) = [\boldsymbol{G}, \boldsymbol{H}]$ for a symmetry $\boldsymbol{H}$, c) $L_{\boldsymbol{G}}(\boldsymbol{\gamma}) = \boldsymbol{\gamma}'[\boldsymbol{G}] + (\boldsymbol{G}')^\dagger(\boldsymbol{\gamma})$ for a cosymmetry $\boldsymbol{\gamma}$.

Let (1)–(3) be an NWD system such that $\partial X_\kappa/\partial t = \partial T_\kappa/\partial t = 0$ for all $\kappa = 1, \dots, c$. Consider a scaling vector field $\boldsymbol{S} = x\boldsymbol{u}_1 + \beta\boldsymbol{u}$, where β is a constant. A function $f \in \mathcal{A}$ such that $\partial f/\partial t = 0$ (resp. some other quantity $\mathcal{X}$ (a symmetry, a cosymmetry etc.) such that $\partial\mathcal{X}/\partial t = 0$) is called *$\boldsymbol{S}$-homogeneous of weight μ* if $L_{\boldsymbol{S}}(f) - xD(f) = \mu f$ (resp. $L_{\boldsymbol{S}}(\mathcal{X}) = \mu\mathcal{X}$) for some constant μ. We write this as $\operatorname{wt} f = \mu$ (resp. $\operatorname{wt}\mathcal{X} = \mu$), cf. e.g. [7,8].

Motivated by the prototypic example of the Korteweg–de Vries equation $u_t = u_3 + uu_1$, let us introduce the following

Definition 1. Let (1)–(3) be an NWD system such that a) $\partial X_\kappa/\partial t = \partial T_\kappa/\partial t = 0$ for all $\kappa = 1, \dots, c$; b) $n \equiv \deg \boldsymbol{F}'$ is odd and $n \geq 3$; c) $\partial\Phi/\partial t = 0$ (recall that Φ is the leading coefficient of $\boldsymbol{F}'$). Further assume that there exists a scaling $\boldsymbol{S} = x\boldsymbol{u}_1 + \beta\boldsymbol{u}$, where β is a constant, such that a) all entries of Φ are $\boldsymbol{S}$-homogeneous, all of them have the same weight $\tilde{\alpha}$, and $\tilde{\alpha} \neq -n$; b) it is possible to choose z_i, introduced in the previous section, in such a way that $\partial z_i/\partial t = 0$, $\exp(2z_i/n)$ are $\boldsymbol{S}$-homogeneous, and $\operatorname{wt}(\exp(2z_i/n)) = \operatorname{wt}(\exp(2z_j/n))$ for all $i, j = 1, \dots, s$. Then we shall call the system (1)–(3) *weakly KdV-like* with the scaling $\boldsymbol{S}$.

Remark 2. Let $\boldsymbol{\zeta} \in SCS_F(\mathcal{A})$ be an $\boldsymbol{S}$-homogeneous time-independent cosymmetry of a weakly KdV-like system (1)–(3), and $k \equiv \deg \boldsymbol{\zeta}' \geq n_0$. Then it is immediate from (8) that

$$\operatorname{wt}(\boldsymbol{\zeta}) = \operatorname{wt}(\exp(2z_1/n)) + ((\tilde{\alpha} + n)/n)k + 2\beta - 1. \tag{10}$$

Note that this formula is very useful on its own, for instance, for finding nonlocal parts of recursion operators and master symmetries for weakly KdV-like systems, cf. [7,8].

Lemma 2. *Assume that* (1)–(3) *is weakly KdV-like with a scaling $\boldsymbol{S}$. Let $\mathcal{L}$ be a subspace of $SCS_F(\mathcal{A})$, and $\mathcal{M}_{\mathcal{L}} = \{\boldsymbol{\zeta} \in \mathcal{L} | \deg \boldsymbol{\zeta}' < n_0$ and $\boldsymbol{\zeta}$ is $\boldsymbol{S}$-homogeneous$\}$.*

Then $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = 0$ for any $\boldsymbol{S}$-homogeneous $\boldsymbol{P} \in \operatorname{Ann}_F(\mathcal{A})$ and any $\boldsymbol{S}$-homogeneous $\boldsymbol{\gamma} \in SCS_F(\mathcal{A})$ such that $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) \in \mathcal{L}$, $p \equiv \operatorname{ford} \boldsymbol{P} \geq n_0$, $\operatorname{wt}\boldsymbol{\zeta} \neq p(\tilde{\alpha} + n)/n + \operatorname{wt}\boldsymbol{\gamma}$ for all $\boldsymbol{\zeta} \in \mathcal{M}_{\mathcal{L}}$, $\boldsymbol{\zeta} \neq 0$, and either p is odd and $\deg\boldsymbol{\gamma}' \geq n_0$ or there exists no integer j such that $j = p + n(\operatorname{wt}\boldsymbol{\gamma} - 2\beta + 1 - \operatorname{wt}(\exp(2z_1/n)))/(\tilde{\alpha} + n)$ and $n_0 \leq j \leq \max(p + n_0 - 2, p + \deg\boldsymbol{\gamma}')$.

Proof. Consider first the case when p is odd and $\deg\boldsymbol{\gamma}' \geq n_0$. Using (10) and the formula $\operatorname{wt}(\boldsymbol{P}) = p(\tilde{\alpha} + n)/n$ from [17], we obtain $\operatorname{wt} L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = \operatorname{wt}(\boldsymbol{P}) + \operatorname{wt}(\boldsymbol{\gamma}) = \operatorname{wt}(\exp(2z_1/n)) + 2\beta - 1 + (p + \deg\boldsymbol{\gamma}')(\tilde{\alpha} + n)/n$. On the other hand, as p is odd and $\deg\boldsymbol{\gamma}' \geq n_0$, a straightforward computation with usage of (8) shows that $\deg(L_{\boldsymbol{P}}(\boldsymbol{\gamma}))' \leq p + \deg\boldsymbol{\gamma}' - 1$. Along with our assumption that $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) \in \mathcal{L}$, this implies that $\deg(L_{\boldsymbol{P}}(\boldsymbol{\gamma}))' < n_0$, and thus $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) \in \mathcal{M}_{\mathcal{L}}$. Indeed, otherwise (10) yields $\operatorname{wt} L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = \operatorname{wt}(\exp(2z_1/n)) + 2\beta - 1 + \deg(L_{\boldsymbol{P}}(\boldsymbol{\gamma}))'(\tilde{\alpha} + n)/n \neq \operatorname{wt}(\exp(2z_1/n)) + 2\beta - 1 + (p + \deg\boldsymbol{\gamma}')(\tilde{\alpha} + n)/n$. Thus, $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) \in \mathcal{M}_{\mathcal{L}}$, but $\operatorname{wt}\boldsymbol{\zeta} \neq \operatorname{wt} L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = \operatorname{wt}(\exp(2z_1/n)) + 2\beta - 1 + (p + \deg\boldsymbol{\gamma}')(\tilde{\alpha} + n)/n$ for all $\boldsymbol{\zeta} \in \mathcal{M}_{\mathcal{L}}$, $\boldsymbol{\zeta} \neq 0$, and hence $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = 0$.

Likewise, if there is no integer j such that $j = p + n(\operatorname{wt}\boldsymbol{\gamma} - 2\beta + 1 - \operatorname{wt}(\exp(2z_1/n)))/(\tilde{\alpha} + n)$ and $n_0 \leq j \leq \max(p + n_0 - 2, p + \deg\boldsymbol{\gamma}')$, then there exists no $\boldsymbol{S}$-homogeneous cosymmetry $\boldsymbol{\zeta} \in \mathcal{L}$ with $\deg\boldsymbol{\zeta}' \geq n_0$ such that $\operatorname{wt} L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = \operatorname{wt}\boldsymbol{\zeta}$, so $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) \in \mathcal{M}_{\mathcal{L}}$, and proceeding as above we conclude that $L_{\boldsymbol{P}}(\boldsymbol{\gamma}) = 0$. ■

4 Applications to recursion operators and master symmetries

Recall [5, 2, 1] that $\mathfrak{R} \in \operatorname{Mat}_s(\mathcal{A})[\![D^{-1}]\!]$ is called a (*adjoint*) *recursion operator* for (1)–(3), if $D_t(\mathfrak{R}) - [\boldsymbol{F}', \mathfrak{R}] = 0$ (resp. $D_t(\mathfrak{R}) + [(\boldsymbol{F}')^\dagger, \mathfrak{R}] = 0$), and a (*inverse*) *Noether operator*, if $D_t(\mathfrak{R}) - \mathfrak{R} \circ (\boldsymbol{F}')^\dagger - \boldsymbol{F}' \circ \mathfrak{R} = 0$ (resp. $D_t(\mathfrak{R}) + \mathfrak{R} \circ \boldsymbol{F}' + (\boldsymbol{F}')^\dagger \circ \mathfrak{R} = 0$).

Consider an operator of the form

$$\mathfrak{R} = \sum_{i=0}^{r} a_i D^i + \sum_{\kappa=1}^{k} \boldsymbol{G}_\kappa \otimes D^{-1} \circ \boldsymbol{\gamma}_\kappa, \tag{11}$$

where $r \geq 0$, a_i are $s \times s$ matrices with local entries, $\boldsymbol{G}_\kappa \in \mathcal{A}^s_{\mathrm{loc}}$, $\boldsymbol{\gamma}_\kappa = \delta\rho_\kappa/\delta\boldsymbol{u}$, and $\rho_\kappa \in \mathcal{A}_{\mathrm{loc}}$ are local conserved densities for (1)–(3), i.e., $D_t(\rho_\kappa) = D(\sigma_\kappa)$ for some $\sigma_\kappa \in \mathcal{A}_{\mathrm{loc}}$.

Proposition 1. *Suppose that a weakly KdV-like system* (1)–(3) *with a scaling* $\boldsymbol{S}$ *has a recursion (resp. inverse Noether) operator of the form* (11) *with* $\boldsymbol{\gamma}_\kappa \in SCS_F(\mathcal{A}_{\mathrm{loc}})$*, and the requirements of Lemma 2 are met for a symmetry* $\boldsymbol{P} \in \mathrm{Ann}_F(\mathcal{A}_{\mathrm{loc}})$ *and for all cosymmetries* $\boldsymbol{\gamma}_\kappa$*,* $\kappa = 1, \ldots, k$*.*

Then $\mathfrak{R}(\boldsymbol{P}) \in S_F(\mathcal{A}_{\mathrm{loc}})$ *(resp.* $\mathfrak{R}(\boldsymbol{P}) \in CS_F(\mathcal{A}_{\mathrm{loc}})$*), i.e.,* $\mathfrak{R}(\boldsymbol{P})$ *is again a* local *symmetry (resp. cosymmetry) for* (1)–(3)*.*

Proof. We have to prove that $\boldsymbol{\gamma}_\kappa \cdot \boldsymbol{P} = D(\eta_\kappa)$ for some local η_κ, or equivalently [2] that $\delta(\boldsymbol{\gamma}_\kappa \cdot \boldsymbol{P})/\delta\boldsymbol{u} = (\boldsymbol{\gamma}'_\kappa)^\dagger(\boldsymbol{P}) + (\boldsymbol{P}')^\dagger(\boldsymbol{\gamma}_\kappa) = 0$. But by Lemma 2 $L_{\boldsymbol{P}}(\boldsymbol{\gamma}_\kappa) = 0$, so $(\boldsymbol{P}')^\dagger(\boldsymbol{\gamma}_\kappa) = -\boldsymbol{\gamma}'_\kappa[\boldsymbol{P}]$, whence $\delta(\boldsymbol{\gamma}_\kappa \cdot \boldsymbol{P})/\delta\boldsymbol{u} = ((\boldsymbol{\gamma}'_\kappa)^\dagger - \boldsymbol{\gamma}'_\kappa)(\boldsymbol{P})$. As $\boldsymbol{\gamma}_\kappa = \delta\rho_\kappa/\delta\boldsymbol{u}$ implies (see e.g. [5]) $(\boldsymbol{\gamma}'_\kappa)^\dagger = \boldsymbol{\gamma}'_\kappa$, we have $\delta(\boldsymbol{\gamma}_\kappa \cdot \boldsymbol{P})/\delta\boldsymbol{u} = 0$, as desired. ■

Consider now an operator of the form

$$\mathfrak{N} = \sum_{i=0}^{r} b_i D^i + \sum_{\kappa=1}^{k} \boldsymbol{\gamma}_\kappa \otimes D^{-1} \circ \boldsymbol{G}_\kappa, \tag{12}$$

where $r \geq 0$, b_i are $s \times s$ matrices with local entries, $\boldsymbol{\gamma}_\kappa \in \mathcal{A}^s_{\mathrm{loc}}$, $\boldsymbol{G}_\kappa \in \mathrm{Ann}_F(\mathcal{A}_{\mathrm{loc}})$ are time-independent local symmetries for (1)–(3). In complete analogy with Proposition 1 we obtain the following result.

Proposition 2. *Let a weakly KdV-like system* (1)–(3) *with a scaling* $\boldsymbol{S}$ *have an adjoint recursion (resp. Noether) operator* $\mathfrak{N}$ *of the form* (12)*. Assume that the requirements of Lemma 2 are met for a* local *time-independent cosymmetry* $\boldsymbol{\zeta} \in SCS_F(\mathcal{A}_{\mathrm{loc}})$ *and for all symmetries* $\boldsymbol{G}_\kappa$*,* $\kappa = 1, \ldots, k$*, and let* $\boldsymbol{\zeta} = \delta\chi/\delta\boldsymbol{u}$ *for some local function* χ*.*

Then $\mathfrak{N}(\boldsymbol{\zeta})$ *is again a* local *cosymmetry (resp. symmetry) for* (1)–(3)*.*

Now let us turn to the case when (1)–(3) has a master symmetry of degree one or equivalently [6] a symmetry linear in time t.

Proposition 3. *Let a weakly KdV-like system* (1)–(3) *with a scaling* $\boldsymbol{S}$ *be such that* $\partial\boldsymbol{F}/\partial t = 0$*,* $\partial\boldsymbol{F}/\partial\omega_\kappa = 0$ *and* $X_\kappa, T_\kappa \in \mathcal{A}_{\mathrm{loc}}$ *for all* $\kappa = 1, \ldots, c$*. Further suppose that* (1)–(3) *has a symmetry* $\boldsymbol{K} = \boldsymbol{\tau} + t[\boldsymbol{\tau}, \boldsymbol{F}] \in S_F(\mathcal{A})$*, where* $\boldsymbol{\tau} = \boldsymbol{\tau}_0 + \sum_{\kappa=1}^{c} \boldsymbol{W}_\kappa\omega_\kappa$*,* $\boldsymbol{\tau}_0 \in \mathcal{A}^s_{\mathrm{loc}}$*,* $\partial\boldsymbol{\tau}_0/\partial t = 0$*, and* $\boldsymbol{W}_\kappa \in \mathrm{Ann}_F(\mathcal{A}_{\mathrm{loc}})$ *for all* $\kappa = 1, \ldots, c$*. Let the requirements of Lemma 2 be met for a* local *time-independent symmetry* $\boldsymbol{P} \in \mathrm{Ann}_F(\mathcal{A}_{\mathrm{loc}})$ *and for all cosymmetries* $\boldsymbol{\gamma}_\kappa = \delta X_\kappa/\delta\boldsymbol{u} \in SCS_F(\mathcal{A}_{\mathrm{loc}})$ *with* $\kappa \in \{1, \ldots, c\}$ *such that* $\boldsymbol{W}_\kappa \neq 0$*. Finally, suppose that* $[\boldsymbol{P}, \boldsymbol{W}_\kappa] = 0$ *for all* $\kappa = 1, \ldots, c$*.*

Then $[\boldsymbol{K}, \boldsymbol{P}]$ *is again a* local *symmetry for* (1)–(3)*.*

Proof. By virtue of the assumptions made $[\boldsymbol{\tau}, \boldsymbol{F}]$ is local [11], and hence so is $[[\boldsymbol{\tau}, \boldsymbol{F}], \boldsymbol{P}]$. Since $[\boldsymbol{P}, \boldsymbol{W}_\kappa] = 0$, it remains to prove that $\omega'_\kappa[\boldsymbol{P}]$ are local or, equivalently, that $\delta(\boldsymbol{\gamma}_\kappa \cdot \boldsymbol{P})/\delta\boldsymbol{u} = 0$ for all $\kappa = 1, \ldots, c$ such that $\boldsymbol{W}_\kappa \neq 0$. This is done as in the proof of Proposition 1 above. ■

Let $\mathrm{ad}_{\boldsymbol{H}}(\boldsymbol{G}) \equiv [\boldsymbol{H}, \boldsymbol{G}]$. Set $\boldsymbol{Q}_j = \mathrm{ad}^j_{\boldsymbol{K}}(\boldsymbol{P})$. Clearly, under minor technical assumptions the repeated application of Proposition 1 (resp. Proposition 3) enables one to prove locality for all symmetries $\mathfrak{R}^j(\boldsymbol{P})$ (resp. $\boldsymbol{Q}_j$), $j = 1, 2, \ldots$, where $\mathfrak{R}$ is a recursion operator for (1)–(3). In particular, the following assertions hold.

Corollary 1. *Under the assumptions of Proposition 1 suppose that $\mathfrak{R}$ is a recursion operator for (1)–(3), r is even, the coefficients of $\mathfrak{R}$ are time-independent, and $\mathfrak{R}$ is $\boldsymbol{S}$-homogeneous of some weight μ, i.e., $L_{\boldsymbol{S}}(\mathfrak{R}) \equiv \mathfrak{R}'[\boldsymbol{S}] - [\boldsymbol{S}', \mathfrak{R}] = \mu\mathfrak{R}$. Further assume that $p \equiv \operatorname{ford} \boldsymbol{P}$ is odd, and for any $j \in \mathbb{N}$ and all $\kappa = 1, \dots, k$ $L_{\mathfrak{R}^j(\boldsymbol{P})}(\boldsymbol{\gamma}_\kappa) \in \mathcal{L}$, $\deg \boldsymbol{\gamma}_\kappa \geq n_0$, and $\operatorname{wt} \boldsymbol{\zeta} \neq (p + rj + \deg \boldsymbol{\gamma}'_\kappa)(\tilde{\alpha} + n)/n + \operatorname{wt}(\exp(2z_1/n)) + 2\beta - 1$ for all $\boldsymbol{\zeta} \in \mathcal{M}_{\mathcal{L}}$, $\boldsymbol{\zeta} \neq 0$.*

Then the symmetries $\mathfrak{R}^j(\boldsymbol{P})$ are local for all $j = 1, 2, 3, \dots$.

Corollary 2. *Under the assumptions of Proposition 3 suppose that $q - n$ is even, $\boldsymbol{\tau}$ is $\boldsymbol{S}$-homogeneous, i.e., $[\boldsymbol{S}, \boldsymbol{\tau}] = \mu\boldsymbol{\tau}$ for some constant μ, $q = \operatorname{ford}[\boldsymbol{\tau}, \boldsymbol{F}] > \max(\operatorname{ford} \boldsymbol{\tau}, n)$, $p \equiv \operatorname{ford} \boldsymbol{P} > n$, p is odd, $[\boldsymbol{Q}_j, \boldsymbol{W}_\kappa] = 0$ and $[\boldsymbol{Q}_j, [\boldsymbol{\tau}, \boldsymbol{F}]] = 0$ for all $\kappa = 1, \dots, c$ and all $j = 0, 1, \dots, b-1$. Further assume that for all $j = 0, \dots, b-1$ and all $\kappa = 1, \dots, c$ such that $\boldsymbol{W}_\kappa \neq 0$ we have $L_{\boldsymbol{Q}_j}(\boldsymbol{\gamma}_\kappa) \in \mathcal{L}$, $\deg \boldsymbol{\gamma}_\kappa \geq n_0$, and $\operatorname{wt} \boldsymbol{\zeta} \neq (p + (q-n)j + \deg \boldsymbol{\gamma}'_\kappa)(\tilde{\alpha} + n)/n + \operatorname{wt}(\exp(2z_1/n)) + 2\beta - 1$ for all $\boldsymbol{\zeta} \in \mathcal{M}_{\mathcal{L}}$, $\boldsymbol{\zeta} \neq 0$.*

Then $\boldsymbol{Q}_j = \operatorname{ad}^j_{\boldsymbol{K}}(\boldsymbol{P})$ are local for all $j = 1, 2, \dots, b$.

Thus, proving locality for the hierarchies generated using master symmetries is slightly more complicated, as we must proceed inductively and make sure that the conditions of Corollary 2 are satisfied for all $b = 1, 2, 3, \dots$. However, this considerably simplifies verification of the relations $[\boldsymbol{Q}_j, \boldsymbol{W}_\kappa] = 0$ and $[\boldsymbol{Q}_j, [\boldsymbol{\tau}, \boldsymbol{F}]] = 0$, because we can use the information on locality obtained at the previous step. There are various ways of proving these relations, see e.g. Proposition 5 of [17] for a scaling-based approach. Note that the conditions $q = \operatorname{ford}[\boldsymbol{\tau}, \boldsymbol{F}] > \max(\operatorname{ford} \boldsymbol{\tau}, n)$ and $p > n$ in Corollary 2 ensure [17] that $\operatorname{ford} \boldsymbol{Q}_{j+1} > \operatorname{ford} \boldsymbol{Q}_j$.

5 Examples

Example 1. Consider the Hirota–Satsuma system (see [21, 7] and references therein)

$$u_t = (1/2)u_3 + 3uu_1 - 6vv_1, \qquad v_t = -v_3 - 3uv_1.$$

and its recursion operator

$$\mathfrak{R} = \begin{pmatrix} D^3/2 + D \circ u + uD & D \circ v + vD \\ D \circ v + vD & D^3/2 + D \circ u + uD \end{pmatrix} \circ \begin{pmatrix} D/2 + D^{-1} \circ u + uD^{-1} & -2D^{-1} \circ v \\ -2vD^{-1} & -2D \end{pmatrix}.$$

The nonlocal part of this operator can be written [7] as $\mathfrak{R}_- = \boldsymbol{G}_1 \otimes D^{-1} \circ \boldsymbol{\gamma}_1 + \boldsymbol{G}_2 \otimes D^{-1} \circ \boldsymbol{\gamma}_2$, where $\boldsymbol{G}_1 = ((1/2)u_3 + 3uu_1 - 6vv_1, -v_3 - 3uv_1)^T$, $\boldsymbol{G}_2 = (u_1, v_1)^T$, $\boldsymbol{\gamma}_1 = (1, 0) = \delta\rho_1/\delta\boldsymbol{u}$ for $\rho_1 = u$, $\boldsymbol{\gamma}_2 = (u, -2v) = \delta\rho_2/\delta\boldsymbol{u}$ for $\rho_2 = u^2/2 - v^2$. It is immediate that the system in question is weakly KdV-like with the scaling $\boldsymbol{S} = x\boldsymbol{u}_1 + 2\boldsymbol{u}$, and the requirements of Proposition 1 are met for any x, t-independent local $\boldsymbol{S}$-homogeneous generalized symmetry $\boldsymbol{P}$ of odd formal order not lower than one, if we set $\mathcal{L} = \{\boldsymbol{\zeta} \in SCS_F(\mathcal{A}_{\mathrm{loc}}) | \partial\boldsymbol{\zeta}/\partial x = 0\}$, and thus the symmetries $\mathfrak{R}^j(\boldsymbol{P})$ are local for all $j = 1, 2, \dots$. In particular, $\mathfrak{R}^j(\boldsymbol{G}_\kappa)$ are local for all $j \in \mathbb{N}$ and $\kappa = 1, 2$.

Example 2. Consider an NWD system with constraints made up from the Schwarzian Korteweg–de Vries equation $u_t = u_3 - (3/2)u_2^2/u_1$, see e.g. [3, 7] and references therein, and the equations defining the potential ω of the conserved density $\rho = (1/2)u_2^2/u_1^2$:

$$u_t = u_3 - (3/2)u_2^2/u_1,$$
$$\partial\omega/\partial t = u_2u_4/u_1^2 - (1/2)u_3^2/u_1^2 - 2u_2^2u_3/u_1^3 + (9/8)u_2^4/u_1^4, \qquad \partial\omega/\partial x = (1/2)u_2^2/u_1^2.$$

It is weakly KdV-like with the scaling $\boldsymbol{S} = xu_1$ and satisfies the requirements of Proposition 3 with $\boldsymbol{P}$ being any x, t, u-independent local $\boldsymbol{S}$-homogeneous symmetry of odd formal order not lower than three, $\mathcal{L} = \{\boldsymbol{\zeta} \in SCS_F(\mathcal{A}_{\mathrm{loc}}) | \partial\boldsymbol{\zeta}/\partial x = 0 \text{ and } \partial\boldsymbol{\zeta}/\partial u = 0\}$, and master symmetry $\boldsymbol{\tau} = u_2 + x(u_3 - (3/2)u_2^2/u_1) - u_1\omega$. Hence by Proposition 3 and Corollary 2 the symmetries $\operatorname{ad}^j_{\boldsymbol{K}}(u_3 - (3/2)u_2^2/u_1) = \operatorname{ad}^j_{\boldsymbol{\tau}}(u_3 - (3/2)u_2^2/u_1)$ are local for all $j = 1, 2, \dots$.

Linear PDE's are considered in the article. The equation to be solved is reduced to the equation on Lagrange submanifold to the coadjoint orbit. As a result we obtained necessary and sufficient conditions of integrability for invariant linear differential equations.

1 Introduction

The most widespread integration method the linear partial differential equations

$$H(z,\partial_z)\varphi(z) = E\varphi(z), \qquad z \in \mathbb{Z} \subset \mathbb{R}^N, \quad \varphi(z) \in C^\infty(\mathbb{Z}) \tag{1}$$

is separation of variables [1] that uses commutative algebra of symmetries of equation (1). The main goal in separation of variables is to solve eigenvalue problem

$$Y_\mu\psi(z) = \lambda_\mu\psi(z), \qquad Y_1 = H, \qquad \lambda_1 = E, \qquad [Y_\mu, Y_\nu] = 0. \tag{2}$$

Commutative algebra of symmetries is not a sufficient condition for the separation of variables. It is necessary for the solvability of system (2) that operators Y_μ must meet additional requirements [2].

Let linear differential equation (1) allow a non-Abelian symmetry group G. We shall now investigate the most efficient way how the non-Abelian symmetry group can be used for the integration of that equation.

2 Main theorem

Let $M = G/H$ be the regular orbit of group action G on Z; x are local coordinates on homogeneous space M, $X_A(x,\partial_x) \equiv X_A^a(x)\partial_{x^a}$ are generators of the transformation group which form Lie algebra $\mathcal{G}$: $[X_A, X_B] = C_{AB}^C X_C$, y are the invariants of the transformation group ($X_A y = 0$), $z \leftrightarrow (x,y)$.

Theorem 1. *Equation* (1) *with N variables that allows a Lie symmetry group G can be reduced to linear differential equations with N' variables:*

$$N' = N - \dim M + d(M), \tag{3}$$

where

$$d(M) = \frac{1}{2}\dim \mathcal{G}/\mathcal{G}^\lambda - \dim \mathcal{H}/\mathcal{H}^\lambda. \tag{4}$$

Here $\mathcal{H}$ is Lie algebra of isotropy subgroup H, λ is regular element of the space $\mathcal{H}^\perp = \{f \in \mathcal{G}^* \mid \langle f, \mathcal{H}\rangle = 0\} \subset \mathcal{G}^*$, $\mathcal{G}^\lambda$ is annihilator of the covector $\lambda \in \mathcal{H}^\perp$, $\mathcal{H}^\lambda = \mathcal{G}^\lambda \cap \mathcal{H}$.

Non-negative integer $d(M)$, which is called *defect* of homogeneous space M can be easily calculated using structural constants of Lie algebra $\mathcal{G}$ and its subalgebra $\mathcal{H}$ [3]:

$$d(M) = \frac{1}{2}\operatorname{rank}\langle\lambda, [\mathcal{G}, \mathcal{G}]\rangle - \operatorname{rank}\langle\lambda, [\mathcal{G}, \mathcal{H}]\rangle.$$

In the case when N' from (3) equals 1 we obtain ordinary differential equation and we call initial equation *integrable*.

Homogeneous spaces for which $d(M) = 0$ are called *commutative*. The class of commutative spaces includes, in particular, all of the symmetric and weakly symmetries spaces [4].

Let us show the main constructions, sufficient for the proof of the Theorem 1 [5].

Let us consider associative algebra D, generated by the finite set of elements $\{E_\mu\}$. Let $\mathcal{F}$ be a linear space with the basis $\{E_\mu\}$, $S(\mathcal{F})$ is a symmetric algebra, then $S(\mathcal{F}) \simeq D$.

We define a skew-symmetric bilinear form (commutator)

$$[A, B] \in S(\mathcal{F}), \qquad \forall\, A, B \in \mathcal{F},$$

such that Jacobi identities are satisfied

$$[A, [B, C]] + [B, [C, A]] + [C, [A, B] = 0, \qquad \forall\, A, B, C \in \mathcal{F}.$$

(We assume here that the form acts on $S(\mathcal{F})$ according to the Leibnitz rule).

For basis elements we have:

$$[E_\mu, E_\nu] = \Omega_{\mu\nu}(E) \in S(\mathcal{F}), \qquad \mu, \nu = 1, \ldots, \dim \mathcal{F}.$$

Algebra $S(\mathcal{F})$ is called *functional algebra* ($\mathcal{F}$-algebra). In particular, if $\Omega_{\mu\nu}$ in formula (4) appears to be a quadratic polynomial, then we call it a quadratic algebra, and so on.

The space of smooth functions on $\mathcal{F}^*$ is Poisson algebra with the Poisson bracket:

$$\{\varphi, \psi\}^{\mathcal{F}}(g) = \Omega_{\mu\nu}(g)\frac{\partial\varphi(g)}{\partial g_\mu}\frac{\partial\psi(g)}{\partial g_\nu}, \qquad g = g_\mu E^\mu \in \mathcal{F}^*, \qquad \varphi, \psi \in C^\infty(\mathcal{F}^*).$$

The Poisson–Lie bracket is defined on the space of functions on $\mathcal{G}^*$:

$$\{\varphi, \psi\}(f) = C^C_{AB} f_C \frac{\partial\varphi(f)}{\partial f_A}\frac{\partial\psi(f)}{\partial f_B}, \qquad f = f_A e^A \in \mathcal{G}^*, \qquad \varphi, \psi \in C^\infty(\mathcal{G}^*). \tag{5}$$

Every Lie group G, acting on homogeneous space M, corresponds to $\mathcal{F}$-algebra of invariant linear operators on $C^\infty(M)$. Let us note as $L_\mu(x, \partial_x)$ independent operators, forming the $\mathcal{F}$-algebra

$$[L_\mu(x, \partial_x), X_A(x, \partial_x)] = 0, \qquad \mu = 1, \ldots, \dim \mathcal{F}, \qquad A = 1, \ldots, \dim \mathcal{G},$$
$$[L_\mu, L_\nu] = \Omega_{\mu\nu}(L) \in S(\mathcal{F}). \tag{6}$$

The dimension of the $\mathcal{F}$-algebra invariant operators is given by the following formula [3]

$$\dim \mathcal{F} = \dim \mathcal{G} + \dim \mathcal{H}^\lambda - 2\dim \mathcal{H}, \qquad \lambda \in \mathcal{H}^\perp. \tag{7}$$

We introduce symbols of operators $X_A(x, p) \equiv X^a_A(x)p_a$, $L_\mu(x, p) \in C^\infty(T^*M)$:

$$\{X_A(x, p), X_B(x, p)\} = C^C_{AB} X_C(x, p), \qquad \{L_\mu(x, p), L_\nu(x, p)\} = \Omega_{\mu\nu}(L), \tag{8}$$
$$\{X_A(x, p), L_\mu(x, p)\} = 0. \tag{9}$$

Momentum mappings

$$\mu:\ T^*X \to \mathcal{G}^*, \quad X(x,p) = f \in \mathcal{G}^*, \qquad \tilde{\mu}:\ T^*X \to \mathcal{F}^*, \quad L(x,p) = g \in \mathcal{F}^*$$

are Poisson mappings on Poisson algebra of functions on T^*M in Poisson algebra on $\mathcal{G}^*$ and $\mathcal{F}^*$. Also symplectic sheets $\Omega \subset \mathcal{G}^*$ and $\tilde{\Omega} \subset \mathcal{F}^*$ mutually correspond [6]:

$$\Omega = \mu\big(\tilde{\mu}^{-1}(\tilde{\Omega})\big), \qquad \tilde{\Omega} = \tilde{\mu}\big(\mu^{-1}(\Omega)\big), \qquad \operatorname{codim}\Omega = \operatorname{codim}\tilde{\Omega}.$$

Let Q be a Lagrange submanifold on the symplectic sheet Ω (coadjoint orbit) in $\mathcal{G}^*$. Let us represent the algebra $\mathcal{G}$ by differential operators $l(q,\partial_q,J)$, which form an irreducible representation of algebra $\mathcal{G}$ in the space of functions on Q [7]:

$$[l_A(q,\partial_q;J), l_B(q,\partial_q;J)] = C^C_{AB} l_C(q,\partial_q;J). \tag{10}$$

Here q are local coordinates on Q, J are parameters, "numerating" orbits in $\mathcal{G}^*$ and satisfying the condition for orbits to be integer.

We note as U a Lagrange submanifold to symplectic sheet $\tilde{\Omega}$. The defect $d(M)$ of homogeneous space M is defined as dimension of Lagrange submanifold to symplectic sheet on the coalgebra of invariant operators [3]:

$$d(M) = \dim U = \frac{1}{2}\dim\tilde{\Omega}. \tag{11}$$

We will note *index* of $\mathcal{F}$-algebra ($\operatorname{ind}\mathcal{F}$) the number of functionally independent elements that generate center of the enveloping field of algebra $\mathcal{F}$.

Obviously the equality

$$\dim\mathcal{F} - \operatorname{ind}\mathcal{F} = \dim\tilde{\Omega} = 2d(M) \tag{12}$$

takes place.

We now construct irreducible representation of algebra $\mathcal{F}$ on Lagrange submanifold U of symplectic sheet $\tilde{\Omega}$ in $\mathcal{F}^*$ with differential operators $\zeta(u,\partial_u;J)$:

$$[\zeta_\mu(u,\partial_u;J), \zeta_\nu(u,\partial_u;J)] = -\Omega_{\mu\nu}(\zeta(u,\partial_u;J)). \tag{13}$$

Set of generalized functions $D^J_{qu}(x)$, is defined from the equations

$$(X_A(x,\partial_x) + l_A(q,\partial_q;J))D^J_{qu}(x) = 0, \qquad (L_\mu(x,\partial_x) - \zeta_\mu(u,\partial_u;J))D^J_{qu}(x) = 0. \tag{14}$$

It is full and orthogonal on $C^\infty(M)$ [5]:

$$\int_M D^{\tilde{J}}_{\tilde{q}\tilde{u}}(x)\overline{D^J_{qu}(x)}\,d\mu(x) = \delta(J,\tilde{J})\delta(q,\tilde{q})\delta(u,\tilde{u}), \tag{15}$$

$$\int D^J_{qu}(x)\overline{D^J_{qu}(\tilde{x})}\,d\mu(J)d\mu(q)d\mu(u) = \delta(x,\tilde{x}). \tag{16}$$

Since operator $H(y,\partial_y,x,\partial_x)$ of equation (1) is G-invariant, so it may be expressed as follows:

$$H(y,\partial_y,x,\partial_x) = F(y,\partial_y,L(x,\partial_x)).$$

Because of that solution basis of equation (1), marked by the parameters (J,q) may be constructed following way:

$$\varphi^J_q(y,x) = \int_U \tilde{\varphi}^J(y,u)D^J_{qu}(x)\,d\mu(u), \tag{17}$$

where function $\tilde{\varphi}^J(y,u)$ is a solution of the equation

$$\tilde{H}(y,\partial_y,u,\partial_u;J)\tilde{\varphi}^J(y,u)=0. \tag{18}$$

Here $H(y,\partial_y,u,\partial_u;J)=F(y,\partial_y,\zeta^+(u,\partial_u;J))$.

Since the expression is correct (11), the number of independent variables N' in equation (18) is defined by formula (3).

Finally from (11) we have the number of independent variables N' in equation (18) to be given by formula (3).

3 Example

Let us illustrate the Theorem presented in this article by a non-trivial example. We consider an equation of type (1), where H is the Laplace operator

$$\Delta\varphi(x)\equiv\frac{1}{\sqrt{g}}\frac{\partial}{\partial x^i}g^{ij}(x)\sqrt{g}\frac{\partial}{\partial x^j}\varphi(x)=E\varphi(x),\qquad g\equiv\det g_{ij} \tag{19}$$

on the Riemannian manifold with metric (below $c_i=\text{const}$)

$$g^{ij}(x)=\begin{pmatrix} c_1e^{2x_4}x_3^2 & c_1e^{2x_4}x_3 & -c_4x_3e^{-x_4}/2 & c_3x_3e^{x_4}/2+c_4e^{-x_4}/2\\ c_1e^{2x_4}x_3 & c_1e^{2x_4} & -c_4e^{-x_4}/2 & c_3e^{x_4}/2\\ -c_4x_3e^{-x_4}/2 & -c_4e^{-x_4}/2 & 0 & 0\\ c_3x_3e^{x_4}/2+c_4e^{-x_4}/2 & c_3e^{x_4}/2 & 0 & c_2 \end{pmatrix}. \tag{20}$$

That metric is not Stakkel which means that Hamilton–Jacobi equation as well as Klein–Gordon and Dirac equations cannot be solved using separation of variables. From the point of existing methods the corresponding equation is not integrable.

Metric (20) allows five-dimensional motion group formed by operators

$$\begin{aligned} &X_1=\partial_1,\qquad X_2=\partial_2,\qquad X_3=x_2\partial_1+\partial_3,\\ &X_4=-x_1\partial_1+x_2\partial_2-2x_3\partial_3+\partial_4,\qquad X_5=x_1\partial_2-x_3^2\partial_3+x_3\partial_4, \end{aligned} \tag{21}$$

that form a basis of the Lie algebra $\mathcal{G}=\{e_A\}$ with the following nonzero commutation rules:

$$\begin{aligned} &[e_1,e_4]=-e_1,\qquad [e_1,e_5]=e_2,\qquad [e_2,e_3]=e_1,\qquad [e_2,e_4]=e_2,\\ &[e_3,e_4]=-2e_3,\qquad [e_3,e_5]=e_4,\qquad [e_4,e_5]=-2e_5. \end{aligned}$$

Here this group acts on a four-dimensional homogeneous Riemannian space with one dimensional isotropy subgroup. Substituting $x=0$ in operators X_A (21), we find isotropy subalgebra $\mathcal{H}=\{e_5\}$. Algebra $\mathcal{G}$ is of an odd index 1, i.e. it has only one Casimir function $K(f)=f_1f_2f_4+f_1^2f_5-f_2^2f_3$, generating center of the Poisson algebra with the Poisson–Lie bracket defined by (5). Regular element of space $\mathcal{H}^\perp$ is non-degenerate and looks like: $\lambda=(\lambda_1,\lambda_2,\lambda_3,\lambda_4,0)$. Annihilator of that covector λ is one-dimensional and, because it is degenerate, is the gradient of Casimir function:

$$\mathcal{G}^\lambda=\big\{\nabla K(f)|_{f=\lambda}=\lambda_2\lambda_4e_1+(\lambda_1\lambda_4-2\lambda_2\lambda_3)e_2-\lambda_2^2e_3+\lambda_1\lambda_2e_4+\lambda_1^2e_5\big\}.$$

So we get: $\mathcal{H}^\lambda=\{0\}$. According to (4) our Riemannian space is non-commutative and its defect is $d(M)=1$. Making a substitution in (3) $N=\dim M=4$, $d(M)=1$, we get $N'=1$, which means according to the Theorem that equation (19) may be reduced to a linear first-order differential equation. Also formulae (7), (12) give $\dim\mathcal{F}=3$, $\operatorname{ind}\mathcal{F}=1$, i.e. the algebra

of invariant operators is three-dimensional and center of enveloping field is generated by one operator.

Let us find the algebra of invariant operators for this case. Symmetry operators X_A are projections of left-invariant vector fields ξ_A: $X_A = \pi_* \xi_A$, where mapping $\pi : G \to M = G/H$ is a projection of group G on the right coset space. Here we note as η_A the algebra of right-invariant vector fields:

$$[\xi_A, \xi_B] = C_{AB}^C \xi_C, \qquad [\eta_A, \eta_B] = C_{AB}^C \eta_C, \qquad [\xi_A, \eta_B] = 0.$$

In canonical coordinates of type II: $g = g_5 g_4 g_3 g_2 g_1$ on the Lie group, where $g_k = \exp(x_k e_k)$, left- and right-invariant vector fields are:

$$\begin{aligned}
&\xi_1 = \partial_1, \qquad \xi_2 = \partial_2, \qquad \xi_3 = x_2\partial_1 + \partial_3,\\
&\xi_4 = -x_1\partial_1 + x_2\partial_2 - 2x_3\partial_3 + \partial_4, \qquad \xi_5 = x_1\partial_2 - x_3^2\partial_3 + x_3\partial_4 + e^{-2x_4}\partial_5,\\
&\eta_1 = -\left(e^{-x_4} + x_3x_5e^{x_4}\right)\partial_1 - e^{x_4}x_5\partial_2, \qquad \eta_2 = -e^{x_4}x_3\partial_1 - e^{x_4}\partial_2,\\
&\eta_3 = -e^{-2x_4}\partial_3 - x_5\partial_4 + x_5^2\partial_5, \qquad \eta_4 = -\partial_4 + 2x_5\partial_5, \quad \eta_5 = -\partial_5.
\end{aligned}$$

(It is obvious that symmetry operators X_A are left-invariant vector fields restricted on the space of functions, which are independent of coordinate x_5). Invariant operators $L(x, \partial_x)$ are operator functions of right-invariant field restricted on the class of functions which are constant on every right coset (in our case functions, which are independent of coordinate x_5) and commuting with every field η_α, which form isotropy algebra $\mathcal{H} = \{\eta_\alpha\}$ (in our case, commuting with η_5). Invariant functions $L(x, p)$, which are symbols of invariant operators are easily obtained:

$$L_\mu(x, p) = a_\mu(f)|_{f=\eta^{cl}}, \qquad \eta_A^{cl} \equiv \eta_A^i(x)p_i,$$

where functions $a_\mu(f) \in C^\infty(\mathcal{G}^*)$ are solutions of the equations

$$\left(C_{\alpha A}^B f_B \frac{\partial a(f)}{\partial f_A}\right)\Bigg|_{f=\lambda} = 0, \qquad \lambda \in \mathcal{H}^\perp, \qquad \alpha = 1, \ldots, \dim \mathcal{H}. \tag{22}$$

In our case equation (22) transforms in

$$f_2\frac{\partial a(f)}{\partial f_1} + f_4\frac{\partial a(f)}{\partial f_3} = 0,$$

As we solve that equation, we get: $a_1 = f_2$, $a_2 = f_4$, $a_3 = f_1f_4 - f_2f_3$. So, invariant functions are:

$$\begin{aligned}
&L_1(x, p) = \eta_2^{cl}(x, p)|_{p_5=0} = -e^{x_4}(x_3p_1 + p_2), \qquad L_2(x, p) = \eta_4^{cl}(x, p)|_{p_5=0} = -p_4,\\
&L_3(x, p) = (\eta_1^{cl}(x, p)\eta_4^{cl}(x, p) - \eta_2^{cl}(x, p)\eta_3^{cl}(x, p))|_{p_5=0} = e^{-x_4}(p_1p_4 - p_2p_3 - x_3p_1p_3).
\end{aligned}$$

Invariant operators look as follows $L(x, \partial_x)$

$$L_1 = ie^{x_4}(x_3\partial_1 + \partial_2), \qquad L_2 = i(\partial_4 + 1), \qquad L_3 = -e^{-x_4}(\partial_{14} - x_3\partial_{13} - \partial_{23}),$$

are self-adjoint in respect to Riemannian measure $\sqrt{g}\,dx = C\exp(2x_4)\,dx$ and form solvable three-dimensional Lie algebra: $i[L_1, L_2] = L_1$, $[L_1, L_3] = 0$, $i[L_2, L_3] = L_3$. Center of the enveloping $\mathcal{F}$-algebra is generated by one element $Z = L_1L_3$, which coincides with Casimir operator $K(-iX)$ for algebra $\mathcal{G}$: $Z(x, \partial_x) = L_1(x, \partial_x)L_3(x, \partial_x) = K(-iX(x, \partial_x))$:

$$L_1L_3 = -i\{X_1, X_2, X_4\} - i\{X_1, X_1, X_5\} + i\{X_2, X_2, X_3\}.$$

Here and below figure brackets note the symmetrized product of operators. The Laplace operator belongs to the enveloping field of the $\mathcal{F}$-algebra since it is invariant operator:

$$-\Delta = c_1 L_1^2(x,\partial_x) + c_2 L_2^2(x,\partial_x) + c_3\{L_1(x,\partial_x), L_2(x,\partial_x)\} + c_4 L_3(x,\partial_x) + c_2. \tag{23}$$

Let us construct an irreducible representation of algebra $\mathcal{G}$ in the space of function on the Lagrange submanifold Q of coadjoint orbit Ω (symplectic sheet) (10):

$$l_1 = iq_1, \qquad l_2 = -iq_2, \qquad l_3 = q_1\partial_{q_2}, \qquad l_4 = q_1\partial_{q_1} - q_2\partial_{q_2}, \qquad l_5 = q_2\partial_{q_1} + iJ/q_1^2, \tag{24}$$

here $(q_1, q_2) \in Q = \mathbb{R}^2$. Because of irreducibility $K(-il(q,\partial_q;J)) = J$. Let us note that operators l_A (24) are skew-Hermitian in respect to measure $d\mu(q) = dq_1 dq_2$ on Q. Parameter J that numerates coadjoint orbits is not quantized and may be of any real value.

Let us construct in the same way irreducible representation of $\mathcal{F}$-algebra in the space of function on Lagrange submanifold U of the symplectic sheet $\tilde{\Omega}$ (13) corresponding with representation (24):

$$\zeta_1 = u, \qquad \zeta_2 = -iu\partial_u, \qquad \zeta_3 = J/u, \qquad \left(u \in U = \mathbb{R}^1\backslash\{0\}\right). \tag{25}$$

These operator are self-adjoint in respect to measure $d\mu(u) = du/u$ on U.

We find set of functions $D^J_{qu}(x)$, numerated by variables (J,q,u) from solution of overdetermined system (14):

$$D^J_{qu}(x) = \exp\left(i(q_2x_2 - q_1x_1) - iJe^{x_4}/q_1u\right)\ \delta\left(e^{x_4}(x_3q_1 - q_2) - u\right). \tag{26}$$

That set of functions satisfies ortogonality and completeness conditions on M (15), (16) (in the right sides of these formulae delta-functions are presented with respect to corresponding measures $d\mu(J) = dJ/(2\pi)^3$).

Let us present solution $\varphi^J_q(x)$ of equation (19) as (17)

$$\varphi^J_q(x) = \int_U \tilde{\varphi}^J(u) D^J_{qu}(x)\, d\mu(u), \tag{27}$$

then, using expressions (14), (23), (25) for function $\tilde{\varphi}^J(u)$ we obtain ordinary differential equation

$$\left(c_2u^2\partial_u^2 + u(c_2 - ic_3u)\partial_u + ic_3u/2 - c_1u^2 - c_4J/u - c_2\right)\tilde{\varphi}^J(u) = E\tilde{\varphi}^J(u).$$

E-mail: *xytang@sjtu.ed.cn, sylou@sjtu.edu.cn*

The conventional Lie group approach is extended successfully to give out the group explanation to the new *conditional* similarity reductions obtained by modifying the Clarkson and Kruskal's (CK's) direct method for the (2+1)-dimensional Korteweg–de Vries (KdV) equation.

1 Introduction

As is well-known that the classical Lie group approach, the nonclassical Lie group approach, the Clarkson and Kruskal's (CK's) direct method are three powerful methods in finding similarity reductions for a given nonlinear partial differential equation (NPDE) [1–6]. In many cases, the similarity reductions obtained by the classical Lie group approach can also be yielded by the CK's direct method; and those obtained by the CK's direct method while not by the classical Lie group approach can be reobtained by the nonclassical Lie group approach. There have been several modifications of these three methods in the literature [7–12].

Three years ago, we for the first time proposed the modified CK's direct method to construct the so-called *conditional* similarity reductions of the (2+1)-dimensional KdV equation in the integrable case [9]. We call a reduction conditional similarity reduction since one reduction field need to satisfy more than one reduction equation. Since then, similar work has been carried out on several other NPDEs including the nonintegrable (2+1)-dimensional KdV equation [10], the Jimbo–Miwa (JM) equation [11] and the Boussinesq equation [12]. It is noticed that the conditional similarity reductions obtained by means of the modified CK's direct method cannot be recovered by utilizing the classical or even the nonclassical Lie group approach in their present forms. The very reason lies in the fact that the constrained equation introduced in the present nonclassical Lie group approach does not offer an additional conditional reduction equation for the reduction field. Consequently, in order to reobtain the conditional similarity reductions by using the classical Lie group approach or the nonclassical Lie group approach, a conditional equation which will lead to the additional reduction equation must be introduced. In Ref. [13], all the conditional similarity reductions of the JM equation resulting from the modified CK's direct method were retrieved by introducing a conditional equation, the KP equation, to form an equation system and then applying the classical Lie group approach to the system. Thus, the whole group theoretical explanation is given of the conditional similarity reductions for the JM equation. In fact, how to introduce a conditional equation so that the conditional similarity reductions got by the modified CK's direct method can also be yielded by the classical Lie group approach and/or the nonclassical Lie group approach has not yet been precisely known.

The aim of this paper is to report the recent progress on the Lie group approach which gives out the group explanation of the conditional similarity reduction solutions obtained by the modified CK's direct method. The modified CK's direct method and the conditional similarity reduction solutions for the (2+1)-dimensional KdV equation will be reviewed in the next section. In Section 3, the conventional Lie group approach is developed further to give out the full group explanation for the conditional similarity reduction solutions given in Section 2. The last section is a short summary and discussion.

2 Conditional similarity reduction solutions

In the traditional CK's direct method, in order to find the similarity solutions of a general Nth order n-dimensional nonlinear system,

$$E_0\left(x_1,x_2,\ldots,x_n,u,u_{x_i},u_{x_ix_j},\ldots,u_{x_1^{i_1}x_2^{i_2}\cdots x_n^{i_n}}\right)\equiv E_0=0,\qquad \sum_{j=1}^{n} i_j=N, \tag{1}$$

one seeks solutions of the kind $u=U(x_1,x_2,\ldots,x_n,P(\xi_1,\xi_2,\ldots,\xi_{n-1}))$, where ξ_j, $j=1,2,\ldots,n-1$ are all functions with respect to $\{x_1,x_2,\ldots,x_n\}$. For some types of models, the solution u may commonly be simplified to the linear ansatz

$$u=\alpha+\beta P(\xi_1,\xi_2,\ldots,\xi_{n-1}), \tag{2}$$

where α and β are both functions of $\{x_1,x_2,\ldots,x_n\}$. In general, it is known that the ansatz (2) may not be valid for other types of models, say, the Harry–Dym equation [3]. Substituting (2) into equation (1) gives out

$$\sum_{l=1}^{L} r_l(\alpha,\alpha_{x_i},\beta,\beta_{x_i},\xi_{x_i},\ldots)F_l(\xi_j,P,P_{\xi_j},\ldots)\equiv\sum_{l=1}^{L} r_lF_l=0. \tag{3}$$

Since the similarity reduction function P satisfies only one reduction equation, equation (3) becomes an $(n-1)$-dimensional PDE $G(\xi_j,P,P_{\xi_j},\ldots)\equiv G(P)=0$, only for all the ratios of r_l being functions of $\{\xi_1,\xi_2,\ldots,\xi_{n-1}\}$. Namely, $r_l=r_k\Gamma_l$ should be satisfied for some fixed nonzero r_k, and Γ_l are functions of $\{\xi_1,\xi_2,\ldots,\xi_{n-1}\}$.

In order to find the conditional similarity reductions of (1), we relax the condition that *the similarity reduction function P satisfies only one reduction equation* as that *P is allowed to satisfy more than one reduction equation at the same time*. Based on this idea, we make use of the same reduction ansatz (2) and then separate the resulting equation (3) into m parts

$$\sum_{k=1}^{m}\sum_{l=1}^{M} A_{lk}F_l=0,\qquad M\geq L, \tag{4}$$

with the condition $\sum\limits_{k=1}^{m} A_{lk}=r_l$, $(l\leq L)$, $\sum\limits_{k=1}^{m} A_{lk}=0$, $(l>L)$, where F_l for $l>L$ may be some suitable functions of P and its partial differential derivatives with respect to $\{\xi_1,\xi_2,\ldots,\xi_{n-1}\}$. Then we can see that the reduction function P may satisfy m reduction equations $\sum\limits_{l=1}^{M} A_{lk}F_l=0$, $(k=1,2,\ldots,m)$. When applying this modified direct method, one must make sure that all the ratios of A_{lk} are functions of $\{\xi_j\}$ for the *same* k, while cannot be functions of $\{\xi_1,\xi_2,\ldots,\xi_{n-1}\}$ for the *different* k. The reason is that if the ratio of any two A_{lk} is a function of $\{\xi_1,\xi_2,\ldots,\xi_{n-1}\}$, then they can be put into the same part of (4). The arbitrariness of m and the functions F_l for $l>L$ makes it a hard job to cover all the cases of the conditional similarity reductions. Therefore, up to now, we have just considered the case $m=2$ and $F_l\equiv 0$ for $l>L$. Obviously, many more meaningful conditional similarity reductions may be found for $m>2$ and/or for $F_l\neq 0$ when $l>L$.

Some types of the conditional similarity reductions of

$$u_{xt}-u_{xxxy}-4u_xu_{xy}-4u_{xx}u_y=0, \tag{5}$$

which is the potential form ($v=u_x$) of the (2+1)-dimensional KdV equation

$$v_t-v_{xxy}-4vv_y-4v_x\partial_x^{-1}v_y=0.$$

have been discussed in detail via the modified CK's direct method in [9]. Here, we will list the general known conditional similarity solution of (5) which reads

$$u=\frac{\eta_t}{4\eta_y}x+\frac{1}{4}\int\left(\frac{\sigma_t\eta_y-\sigma_y\eta_t}{\theta\eta_y}+\theta(\omega_{14}\sigma+B\sigma_y)+\gamma_{14}\sigma\eta_y\right)\mathrm{dy}+\theta P,\qquad \xi=\theta x+\sigma,$$

where the function $P=P(\xi,\eta)$ satisfies the conditional similarity reduction equations (i.e. (116) and (117) of Ref. [9])

$$P_{\xi\xi\eta}+4P_\xi P_\eta+\gamma_{14}(\xi P_\xi-P)+\gamma_{29}P+(\gamma_{21}\eta+\gamma_{20})\xi+f_1=0,$$
$$P_{\xi\xi\xi}+4P_\xi^2+\omega_{14}(\xi P_\xi-P)+BP_\xi+\omega_{29}P+(\omega_{21}\eta+\omega_{20})\xi+f_0=0,$$

with $B=B(\eta)$, $f_1=f_1(\eta)$ and $f_0=f_0(\eta)$ being arbitrary functions of η. For the other functions ($\theta=\theta(t)$, $\sigma=\sigma(y,t)$, $\eta=\eta(y,t)$) and constants (γ_{14}, γ_{29}, γ_{21}, γ_{20}, ω_{14}, ω_{29}, ω_{21}, ω_{20}), seven possible selections were given in [9] which will be explicitly written down again in Table 1 later.

3 Group explanation of the conditional similarity reduction solutions

In order to give out the whole group theoretical explanation of the conditional similarity reductions obtained via the modified CK's direct method described in the last section, we have to extend the present classical Lie group approach and the nonclassical Lie group approach.

Simply speaking, the extended classical and nonclassical conditional Lie group approaches are realized if we introduce some constrained equations when solving the model equation and then applying the standard group approach to the formed equation system. As a first attempt, we worked on the JM equation [13] where the conditional similarity reductions yielded by the modified CK's direct method have been recovered totally. However, the constrained equation in this case comes quite specifically so that it cannot be a good candidate for all the NPDEs in observation. Consequently, a more systemic way should be established to find out a common equation which can then be considered for a class of NPDEs. Starting from this standpoint, a more general conditional equation for the integrable (2+1)-dimensional KdV equation is imported when we try to give out the group explanation of the results [9] obtained via the modified CK's direct method, which read

$$u_{xxx}+A_1u_{xxy}+A_2u_xu_y+A_3u_x+A_4u_y+A_5u_x^2+A_6u+A_7=0, \tag{6}$$

with the coefficients A_i, $(i=1,2,\ldots,7)$ being suitable functions with respect to the space-time variables $\{x,y,t\}$ to be determined later. Writing down the constrained equation (6) is based on the fact that the orders of the differentiations and the nonlinearity of the conditional reductions obtained by the modified CK's direct method in [9] are not higher than those of the original system (5). Like the conventional nonclassical Lie group approach, when using the extended nonclassical Lie group approach, we have to utilize the following constraint condition

$$Xu_x+Yu_y+Tu_t-U=0, \tag{7}$$

where X, Y, T, U of $\{x,y,t,u\}$ are called the infinitesimals of the transformation functions related to the infinitesimal transformations $\{x,y,t,u\}\to\{x,y,t,u\}+\epsilon\{X,Y,T,U\}$ with ϵ being the group parameter, under which the model equation and the constrained equations should be form invariant.

Ignoring the concrete calculations, we directly give out the whole group explanation in Table 1 where the first column is the selections corresponding to the known conditional similarity solutions in Ref. [9], the second column is the solutions for the coefficients of the constrained equation (6) and the last column is the concrete form of the related infinitesimal transformations.

Table 1. Group explanation for the results obtained by the modified CK's direct method.

	Selections	Parameters	Infinitesimal Transformations

Hence, the full group theoretical explanation is given out for all the conditional similarity reductions of the integrable (2+1)-dimensional KdV equation obtained by the modified CK's direct method in Ref. [9]. It is worth pointing out that the coefficients of the conditional equation used in giving out the group explanation of the results resulting from the modified CK's direct method are permitted to be functions with respect to the space-time arguments. In the case that all the coefficients in this added equation are fixed to be constants, we are still able to find many conditional symmetry reductions by utilizing the extended classical and nonclassical Lie group approaches [14] which are definitely recoverable by the modified direct method though the related work has not yet been carried out.

4 Summary and discussions

By extending both the CK's direct method and the Lie group approach, we can obtain the conditional similarity reductions. The crucial point for this kind of reduction is that the one reduction field of a given NPDE needs to satisfy more than one reduction equation. From the detailed description in the last two sections, one can notice much freedom or arbitrariness in both the modified CK's direct method and the extended Lie group approach. For the modified CK's direct method, we need to separate the resulting equation (3). Obviously, the division is quite arbitrary. Moreover, the values of F_l for $l > L$ can be set arbitrarily. While for the extended Lie group approach, the choice of the constrained equation is rather arbitrary. Many different useful results will be generated with different selections of the conditional equations. Anyhow, we do believe that the conditional similarity reductions obtained from the modified CK's direct method can definitely be reobtained from the extended Lie group approach and vice versa through ascertaining or balancing the arbitrariness between these two methods.

Furthermore, on the other hand, one can also see that the constrained equations introduced in the extended Lie group approach have little relation with the model equation under investigation. However, as for the nonintegrable JM equation, the conditional equation forms an integrable system with the JM equation. Therefore, probably we can decrease the arbitrariness by considering a constrained equation which has some possible relation with the studied equation especially for the nonintegrable models. All in all, the search of a method to introduce

a constrained equation for the model equation into the extended classical and nonclassical Lie group approaches is still in progress.

Dynamical Symmetries of Autonomous Differential Second Order Equations

Mikhail I. TIMOSHIN

Samara State Pedagogical University, Russia
E-mail: *midvolga@mail.ru*

In the report the possibility of dynamic symmetries to an analytical integration of autonomous ODE of second order is presented. The correlation with known results is pointed out. The concept of a defining system of dynamic symmetries is given. The example indicating to the effectiveness of an offered method is produced.

1 Introduction

The concept of dynamic symmetry is given, for example, in [1]. The differential equation, in this case, is replaced by ODE system of the first order:

$$y'' = f(x, y, y') \;\Leftrightarrow\; \frac{dy}{dx} = z, \qquad \frac{dz}{dx} = f(x, y, z). \tag{1}$$

Then it is possible to consider the question of an infinitesimal transformation

$$X = \xi(x, y, z)\frac{\partial}{\partial x} + \eta(x, y, z)\frac{\partial}{\partial y} + \mu(x, y, z)\frac{\partial}{\partial z}, \tag{2}$$

translating a solution of system (1) again into a solution. That is operator (2) should satisfy the condition

$$[X, A] = \lambda(x, y, z)A, \tag{3}$$

where

$$A = \frac{\partial}{\partial x} + z\frac{\partial}{\partial y} + f(x, y, z)\frac{\partial}{\partial z}.$$

As against the contact symmetries, set by the characteristic function $\Omega(x, y, z)$

$$X = \Omega_z\frac{\partial}{\partial x} + (z\,\Omega_z - \Omega)\frac{\partial}{\partial y} - (\Omega_x + z\,\Omega_y)\frac{\partial}{\partial z},$$

of the operator of dynamic symmetry (2), the components ξ, η, μ are defined only by condition (3).

2 Dynamical symmetries of autonomous differential second order equations

Let us consider the autonomous differential equation of the second order

$$y'' = f(y, y'). \tag{4}$$

The equation (4) admits point symmetry $X_1 = \frac{\partial}{\partial x}$ and dynamic symmetry X_2. Following the scheme of S. Lie, we shall write out the most general transformations retaining autonomy (4). For this purpose it is necessary that the transformed system should suppose symmetry $\bar{X}_1 = \frac{\partial}{\partial t}$. Thus two cases are possible:

I uncrossed transformation **II crossed transformation**

$$X_1 \Leftrightarrow \bar{X}_1 \qquad\qquad X_1 \quad \bar{X}_1$$

$$\qquad\qquad\qquad\qquad \times$$

$$X_2 \Leftrightarrow \bar{X}_2 \qquad\qquad X_2 \quad \bar{X}_2$$

In case of **I** transformations have the form

$$x = t + \alpha(u, w), \qquad y = \beta(u, w), \qquad z = \gamma(u, w). \tag{5}$$

In case of **II** transformations will be defined by a choice of the form of the transformed dynamic system. By taking dynamic system

$$\frac{du}{dt} = R(w)u + P(w), \qquad \frac{dw}{dt} = Q(w), \tag{6}$$

it is possible to speak about linearizing of the equation (4) according to the circuit **I** or **II**. In case of **I** the class of linearizing equations is most clearly defined

$$y'' = \begin{vmatrix} \dfrac{d^2\beta}{dt^2} & \dfrac{d\beta}{dt} \\ \dfrac{d^2(t+\alpha)}{dt^2} & \dfrac{d(t+\alpha)}{dt} \end{vmatrix} \Bigg/ \left(\frac{d\,(t+\alpha)}{dt}\right)^3. \tag{7}$$

The general solution of the equation (7) has the form:

$$\begin{aligned} x &= \int \frac{dw}{Q(w)} + \alpha(u, w) + C_1, \qquad y = \beta(u, w), \\ u &= e^{\int \frac{R(w)}{Q(w)} dw} \left(\int \frac{P(w)}{Q(w)} e^{-\int \frac{R(w)}{Q(w)} dw} dw + C_2 \right). \end{aligned} \tag{8}$$

Before consideration of type **II** transformation we shall present additional information concerning dynamic symmetries. In the book [1] it is pointed out that if the symmetry X of dynamic system of the equations determined by the operator A is known, then

$$\hat{X} = X + \rho(x, y, z)A \tag{9}$$

with any function $\rho(x, y, z)$, is also a dynamic symmetry. That is explained by the fact that the following

$$[\hat{X}, A] = \lambda A - (A\rho)A = \hat{\lambda} A$$

takes place. Using ratio (9) it is always possible to proceed from the operator X to the operator $\widehat{X}$ at which the coefficient at $\frac{\partial}{\partial x}$ will be equal to zero. In the case of point symmetry

$$X = \xi(x, y)\frac{\partial}{\partial x} + \eta(x, y)\frac{\partial}{\partial y} + \cdots \tag{10}$$

and a differential equation of the second order $y'' = f(x, y, y')$ we shall obtain

$$\hat{X} = (\eta - y'\xi)\frac{\partial}{\partial y} + \cdots . \tag{11}$$

In the book [2] the proof by Boyer (1967) that the operators (10), (11) are equivalent is presented. By repeating Boyer's reasonings it is easy to show that in case of dynamic system

$$\frac{dy}{dx}=\varphi(x,y,z),\qquad \frac{dz}{dx}=f(x,y,z),\qquad A=\frac{\partial}{\partial x}+\varphi(x,y,z)\frac{\partial}{\partial y}+f(x,y,z)\frac{\partial}{\partial z},$$

generators

$$X=\xi(x,y,z)\frac{\partial}{\partial x}+\eta(x,y,z)\frac{\partial}{\partial y}+\mu(x,y,z)\frac{\partial}{\partial z}\qquad\text{and}\qquad \hat{X}=(\eta-\varphi\xi)\frac{\partial}{\partial y}+(\mu-f\xi)\frac{\partial}{\partial z}$$

are equivalent. Let us consider now linearization of the second type. By taking as new variables the first integrals of the system (6)

$$s=ue^{-\int\frac{R(w)}{Q(w)}dw}-\int\frac{P(w)}{Q(w)}e^{-\int\frac{R(w)}{Q(w)}dw}dw,\qquad v=\int\frac{dw}{Q(w)}-t,$$

we shall obtain the following system

$$\frac{ds}{dt}=0,\qquad \frac{dv}{dt}=0. \tag{12}$$

The system (12) has the dynamic symmetry

$$X=\xi(t,s,v)\frac{\partial}{\partial t}+\eta(s,v)\frac{\partial}{\partial s}+\mu(s,v)\frac{\partial}{\partial v}$$

with any functions $\xi(t,s,v)$, $\eta(s,v)$, $\mu(s,v)$. Going back to variables t, u, w we shall obtain the dynamic symmetry of system (6)

$$X=(\xi+\mu)\frac{\partial}{\partial t}+\left[(\xi+\mu)(R(w)u+P(w))+\eta e^{\int\frac{R(w)}{Q(w)}dw}\right]\frac{\partial}{\partial u}+(\xi+\mu)Q(w)\frac{\partial}{\partial w}.$$

Going from the found symmetry to the equivalent operator, we obtain dynamic symmetry in the following form

$$\hat{X}=\eta e^{\int\frac{R(w)}{Q(w)}dw}\frac{\partial}{\partial u}. \tag{13}$$

The most general transformation reducing the generator (13) to $\frac{\partial}{\partial x}$ has the form

$$x=\alpha(s,v)+\Phi(t,w),\qquad y=\Psi(t,w),\qquad z=\Omega(t,w), \tag{14}$$

where $\alpha_s=\frac{1}{\eta(s,v)}$. The transformation (14) allows to proceed from system (6) to system

$$\frac{dy}{dx}=\left(\frac{d}{dt}\Psi(t,w)\right)\Big/\left(\frac{d}{dt}\Phi(t,w)\right),\qquad \frac{dz}{dx}=\left(\frac{d}{dt}\Omega(t,w)\right)\Big/\left(\frac{d}{dt}\Phi(t,w)\right). \tag{15}$$

To bring system (15) into correspondence with equation (4) it is necessary to put

$$z=\Omega(t,w)=\left(\frac{d\Psi}{dt}\right)\Big/\left(\frac{d\Phi}{dt}\right). \tag{16}$$

Thus we obtain the second class of linearizing autonomous ODE of the second order as

$$y''=\begin{vmatrix}\frac{d^2\Psi}{dt^2} & \frac{d\Psi}{dt}\\ \frac{d^2\Phi}{dt^2} & \frac{d\Phi}{dt}\end{vmatrix}\Big/\left(\frac{d\Phi}{dt}\right)^3. \tag{17}$$

The general solution of the equation (17) looks as follows:

$$x = C_1 + \Phi(t, w), \qquad y = \Psi(t, w), \qquad t = C_2 + \int \frac{dw}{Q(w)}. \tag{18}$$

Comparing the general solutions (8), (18) it is easy to notice that they will coincide if in (8) functions α, β are considered as depending on arguments s, w: $\alpha = \alpha(s, w)$, $\beta = \beta(s, w)$, and in (18) functions Φ, Ψ depending on arguments v, w: $\Phi = \Phi(v, w)$, $\Psi = \Psi(v, w)$. It makes possible to speak not about two classes of autonomous ODE of the second order but about one. Of three functions Ω, Ψ, Φ only two are independent, the third function is determined from a condition (16). By taking as arguments variables t, v it is easy to obtain well known results. With the help of functions $\Omega(t, v)$, $\Psi(t, v)$ the autonomous differential equation of the second order is determined as

$$\Omega \frac{d\Omega}{dt} = \frac{d\Psi}{dt} f(\Psi, \Omega). \tag{19}$$

In spite of the fact that at transition from the equation (4) to the equation (19) there was a reduction of the order, it does not always facilitate a task of integration of the differential equations.

The group approach with the help of criterion (3) allows to receive additional equations of the second order with respect to required functions Ω, Ψ, Φ. In the coordinate form the criterion (3) is equivalent to the system of two equations of the form:

$$\begin{aligned} &\mu - \eta_x - z\eta_y - f\eta_z + z\xi_x + z^2\xi_y + zf\xi_z = 0, \\ &\eta f_y + \mu f_z - \mu_x - z\mu_y - f\mu_z + f\xi_x + zf\xi_y + f^2\xi_z = 0. \end{aligned} \tag{20}$$

The transformation (14) allows to write out the type of dynamic symmetries in variables x, y, z:

$$X = (\Phi_t - \alpha_v)\frac{\partial}{\partial x} + \Psi_t \frac{\partial}{\partial y} + \Omega_t \frac{\partial}{\partial z}.$$

Replacing in the adduced out system variables y, z with the help of the formulas (14), and adding the equations

$$\Psi_t + \Psi_w Q - (\Phi_t + \Phi_w Q)\Omega = 0, \qquad \Omega_t + \Omega_w Q - (\Phi_t + \Phi_w Q) f(\Psi, \Omega) = 0, \tag{21}$$

we can receive a system of four equations with three unknown functions. As against classical system of the determining equations used while finding point symmetries, the constructed system of the equations is not linear. However, it is easy to notice, that with the help of the equations (21) equations with partial derivatives can be reduced to the ordinary differential equations of the second order, in which one of variables plays a role of parameter. It makes possible to apply the well elaborated algorithms of point symmetries to investigation of the constructed system of the determining equations of dynamic symmetries.

3 Example

As a testing example underlining efficiency of the offered technique, we shall consider the equation of the second order having the form

$$y''(A + By') + y'^3 C + y'^2 D + y' E = 0 \tag{22}$$

where

$$A = r_3 l^2 k - r_1 k^3 - r_3 h^2 k^3 - r_2 k^3 h - k^2 g_1 l,$$

$$B = 2r_3kl - r_2k^2 - 2r_3hk^2 - k^2g_1,$$
$$C = r_2kk_y - r_3k_yl - r_3kl_y + r_3h_yk^2 + 2r_3hkk_y + g_1kk_y,$$
$$D = r_1k^2k_y + 2r_3h_yk^2l + g_1kk_yl + r_2kk_yl + 2r_3hkk_yl + r_2hk^2k_y + r_3h^2k^2k_y - g_1k^3h_y - r_2k^2l_y - 2r_3hk^2l_y - r_3l^2k_y,$$
$$E = r_1k^2k_yl + r_2k^2k_yhl + r_3l^2k^2h_y - g_1k^3lh_y + r_3h^2k^2k_yl - r_3h^2k^3l_y - r_1k^3l_y - r_2k^3hl_y,$$

in which k, l, h are arbitrary functions of argument y, and r_1, r_2, r_3, g_1 are arbitrary constants.

Using the standard method of reduction to form (19), from the equation (22) we obtain the Abel equation of the second type

$$\frac{d\Omega}{dy}(A + B\Omega) + \Omega^2C + \Omega D + E = 0. \tag{23}$$

The equation (22) is linearized with the help of transformation

$$u = \frac{k}{z+l} - \frac{r_3+1}{g_1}, \qquad w = \frac{z}{k} + h. \tag{24}$$

Thus we obtain equation

$$\left(r_1 + r_2w + r_3w^2\right)\frac{du}{dw} = g_1u + 1,$$

whose general solution looks as follows:

$$(u + 1/g_1) - C_2e^{\int \frac{g_1dw}{r_1+r_2w+r_3w^2}} = 0. \tag{25}$$

For representation of the general solution of the equation (22) as (8), it is necessary to define the form of function $\alpha(u, w)$. Using ratio (5), and considering the function α on arguments (y, C_2) we obtain expression

$$\alpha(y, C_2) = \int\left(\frac{1}{z} + \frac{kl_y - k_yl - h_yk^2}{(kr_2 - 2r_3l + 2r_3hk + kg_1)z - l^2r_3 + k^2r_1 + lkg_1 + r_3h^2k^2 + k^2hr_2}\right)dy.$$

In this case the integral is calculated with the assumption that variable z is function from y determined by ratios (24), (25). Thus the general solution of equation (22) has the form

$$x = \alpha(y, C_2) + \int \frac{dw}{r_1 + r_2w + r_3w^2} + C_1,$$
$$\frac{k}{z+l} - \frac{r_3}{g_1} + C_2e^{\int \frac{g_1dw}{r_1+r_2w+r_3w^2}} = 0, \qquad w = \frac{z}{k} + h.$$

Let us also note that last two equations give the general solution of Abel equation (23). It is interesting to notice that in variable y, $w(y)$ equation (23) takes the form

$$r_1 + r_2w + r_3w^2 + \frac{dw}{dy}\left\{\frac{w\left(2r_3k(l-kh) - k^2(g_1+r_2)\right) - r_1k^2 + r_3(l-kh)^2 + kg_1(kh-l)}{k_yl - kl_y + h_yk^2}\right\} = 0,$$

and the standard transformation is brought to the canonic form:

$$\frac{d\vartheta}{d\tau}\vartheta + \vartheta + \frac{3\tau}{16} - \frac{3^{\frac{2}{3}}\left(2g_1^2\lambda^{\frac{4}{3}} - r_3\lambda^{\frac{1}{3}}\right)}{24\tau^{\frac{1}{3}}r_3^2\lambda^{\frac{2}{3}}} + \frac{3^{\frac{1}{3}}}{144\tau^{\frac{5}{3}}r_3^2\lambda^{\frac{2}{3}}} = 0, \tag{26}$$

where

$$\lambda = \frac{r_3}{g_1^2 + 4r_3r_1 - r_2^2}.$$

In directory [3] the transformation of equation of type (26) into another Abel equation and then to Riccati equation is presented. The obtained equation was integrated by Koyalovich [4]. The author of the directory asserts that the form of the obtained solution is very bulky and consequently it was not presented. In [3] solutions of special cases of the equation (26) through Bessel's functions are also given.

4 Concluding remark

In the conclusion we shall note that the proposed approach to investigation of integrated cases of the autonomous differential equations of the second order can be considered as some analogue of the Galois theory for polynomials. In investigating the solubility of the equation

$$P_n = x^n + a_1x^{n-1} + a_2x^{n-2} + \cdots + a_{n-1}x + a_n = 0,$$

the various ratios between roots of x_i equation are considered, i.e. the equation is replaced with a system of the equations for roots $F_1(x_{i_1}, x_{i_2}, \ldots, x_{i_k}) = 0$, …, $F_m(x_{i_1}, x_{i_2}, \ldots, x_{i_r}) = 0$, which can be solved easier than the initial equation.

In the proposed method the question of integration of differential equations is actually reduced to investigation of the system of differential equations

$$F_i(x, y, z, x_t, y_t, z_t, x_w, y_w, z_w, x_{tw}, y_{tw}, z_{tw}, x_{tt}, y_{tt}, z_{tt}, x_{ww}, y_{ww}, z_{ww}) = 0,$$

where $i = 1, 2, 3, 4$. And while investigating the constructed system, the standard algorithms of the group analysis can be used.

E-mail: *tsyfra@math.uwb.edu.pl*

We propose the symmetry reduction method of partial differential equations to the system of differential equations with fewer number of independent variables. We also obtain generalized sufficient conditions for the solution found by conditional symmetry method to be an invariant one in classical sense.

1 Introduction

In recent years the symmetry method is often used for reduction of partial differential equations to the equations with fewer number of independent variables and thus for construction of exact solutions for different mathematical physics problems. To construct a corresponding ansatz generators of classical Lie point transformations are used as well as operators of conditional symmetry. In this connection the application of combination of conditional and generalized symmetry is fruitful as was shown in [1,2] on the examples of evolution equation in two-dimensional case (see also [3]). In [4] Svirshchevskii proposed the symmetry reduction method based on the invariance of linear ordinary differential equations (see also [5]). It is the symmetry explanation of "nonlinear" separation of variables [6] for the evolution-type equations.

Here we propose an approach applicable for symmetry reduction of partial differential equations which are not restricted to evolution type ones. It can be used in multi-dimensional case. This approach is the generalization of the method introduced in [4].

2 Generalized symmetry and reduction of partial differential equations

Let us consider partial differential equation

$$U\big(x,u,\underset{1}{u},\underset{2}{u},\ldots,\underset{k}{u}\big)=0, \tag{1}$$

where $x=(x_1,x_2,\ldots,x_n)$, $u=u(x)\in C^k\big(\mathbb{R}^n,\mathbb{R}^1\big)$, and $\underset{k}{u}$ denotes all partial derivatives of k-th order. Replacing u by $u+\epsilon w$ and then equating coefficients at ϵ in Taylor series expansion we obtain linearized equation (1)

$$L(x,u,w)=0. \tag{2}$$

It has been proved that the following property is fulfilled in this case. If equation (1) admits Lie–Bäcklund vector field $Q=\eta\big(x,u,\underset{1}{u},\underset{2}{u},\ldots,\underset{r}{u}\big)\partial_u$ and $u=f(x)$ is a solution of equation (1) then

$$w=Qu\big|_{u=f(x)} \tag{3}$$

is a solution of equation (2).

This property is illustrated by the connection between the solutions of Liouville and Moutard equations. It is well known that the Liouville equation

$$u_{xy} = 2\exp u \tag{4}$$

is invariant with respect to the Lie group of transformations with the generator

$$Q_1 = f(x)\partial_x + g(y)\partial_y - (f' + g')\partial_u,$$

where $f(x)$ and $g(y)$ are arbitrary smooth functions. Then from the solution

$$u = \ln \frac{X'Y'}{(X+Y)^2}$$

of Liouville equation we easily obtain the solution

$$u = \frac{X_1'}{X'} + \frac{Y_1'}{Y'} - 2\frac{X_1 + Y_1}{X+Y}$$

of the Moutard equation

$$w_{xy} = 2\frac{X'Y'}{(X+Y)^2}w$$

with potential $V = 2\frac{X'Y'}{(X+Y)^2}$, where $X(x)$, $Y(y)$ are arbitrary smooth functions of their arguments, $fX' = X_1$, $gY' = Y_1$, by using (3).

This property can also be used for reduction of partial differential equations to system of equations with smaller number of independent variables. For simplicity consider ordinary differential equation

$$H\big(x, u, \dots, \underset{m'}{u}\big) = 0, \tag{5}$$

where $\underset{m'}{u}$ denotes the derivative of u with respect to one variable x_1 of m'-th order, and H are a smooth function of its arguments. Suppose that Q is the operator of Lie–Bäcklund symmetry of equation (5). Let

$$u = F(x, C_1, \dots, C_{m'}), \tag{6}$$

where F is a smooth function of variables x, $C_1, \dots, C_{m'}$, $C_1, \dots, C_{m'}$ are arbitrary functions of parametric variables $x_2, x_3, \dots, x_n$, be a general solution of equation (5). Then operator Q transforms solution (6) to the solution of linearized version of equation (5), i.e. the linear homogeneous ordinary differential equation. It means that Q maps the set of solutions (6) into a m'-dimensional vector space M. Moreover, we proved that partial derivatives $\frac{\partial F}{\partial C_i}$, $i = \overline{1, m'}$ form the basis of M provided that H, U and F are sufficiently smooth functions of their arguments. In this connection the following statement holds.

Theorem 1. *Let equation* (5) *be invariant with respect to the Lie–Bäcklund operator* Q*. Then the ansatz*

$$u = F(x, \phi_1, \phi_2, \dots, \phi_{m'}), \tag{7}$$

where $\phi_1, \phi_2, \dots, \phi_{m'}$ *depend on* $n-1$ *variables* $x_2, x_3, \dots, x_n$ *reduces partial differential equation*

$$\eta\big(x, u, \underset{1}{u}, \underset{2}{u}, \dots, \underset{r}{u}\big) = 0 \tag{8}$$

to the system of k_1 *equations for unknown functions* $\phi_1, \phi_2, \dots, \phi_m$ *with* $n-1$ *independent variables and* $k_1 \le m'$*.*

Taking into account the above-mentioned arguments we proved the theorem. It can be easily generalized for $\phi_1, \phi_2, \ldots, \phi_{m'}$ depending on $\omega_l(x)$, $l = \overline{1, n-1}$, where $\omega_l(x)$ are some functions of variables x. Note that the case when equation (5) is linear ordinary differential equation and η is the function of special type (evolution type) considered in [4].

We consider several examples illustrating the application of the theorem. Firstly consider equation

$$u_t = f(u_x)u_{xx}, \tag{9}$$

where $f(u_x)$ is a smooth function of u_x. Let us consider the equation (5) in the following form

$$u_{xx} = u_x^3. \tag{10}$$

In accordance with our approach we study the invariance of the equation (10) with respect to Lie–Bäcklund operator

$$K_1 = (u_t - f(u_x)u_{xx})\partial_u. \tag{11}$$

Function $f(u_x)$ is determined from the condition of invariance of the equation (10) with respect to the operator (11). It has the form

$$f = \frac{A}{u_x^3} + \frac{B}{u_x^2},$$

where A, B are arbitrary real constants. Then we proved that the equation (10) admits the operators

$$K_2 = uu_x\partial_u, \qquad K_3 = h\left(u + u_x^{-1}\right)\partial_u,$$

where h is arbitrary smooth function. Therefore the equation (10) is invariant with respect to the group of Lie–Bäcklund transformations with infinitesimal operator $\alpha_1 K_1 + \alpha_2 K_2 + \alpha_3 K_3$, where α_1, α_2, α_3 are arbitrary real constants. From this it follows that the theorem can be used for the equation

$$u_t = \left(\frac{A}{u_x^3} + \frac{B}{u_x^2}\right)u_{xx} + \lambda u u_x + \lambda_1 h\left(u + u_x^{-1}\right), \tag{12}$$

where λ, λ_1 are arbitrary real constants. The ansatz corresponding to the equation (10) has the form

$$u = \phi_2(t) - \sqrt{\phi_1(t) - 2x}, \tag{13}$$

where $\phi_1(t)$ and $\phi_2(t)$ are unknown functions. The ansatz (13) reduces the equation (12) to the system of ordinary differential equations

$$\phi_2' = A - \lambda + \lambda_1 h(\phi_2), \qquad -\phi_1' = 2(B + \lambda\phi_2). \tag{14}$$

For different $h(\phi_2)$ we receive different solutions. Let $h(\phi_2) = \phi_2$. In this case the solution of the system (14) is

$$\phi_2 = Ce^{\lambda_1 t} - (A - \lambda)\lambda_1^{-1}, \qquad -\phi_1 = 2\left(B - (A - \lambda)\lambda\lambda_1^{-1}\right)t + 2\lambda_1^{-1}\lambda C e^{\lambda_1 t} - C_1. \tag{15}$$

Substituting (15) into (13) we obtain the solution

$$u = Ce^{\lambda_1 t} - (A - \lambda)\lambda_1^{-1} - \sqrt{2\left((A - \lambda)\lambda\lambda_1^{-1} - B\right)t - 2\lambda_1^{-1}\lambda C e^{\lambda_1 t} + C_1 - 2x}$$

of equation (12). This solution cannot be obtained by using classical Lie method of point symmetry.

Note that the ansatz (13) can be used also for reduction of equations obtained by commuting of operators K_1, K_2, K_3.

Next we show the application of the method to an equation associated with inverse scattering problem. As we know the group-theoretical background of the inverse scattering problem method was given for the first time in [7].

Namely we study the symmetry of the linear ordinary differential equation

$$u_{xx} = f(t,x)u. \tag{16}$$

where variable t play the role of parameter in this equation, with respect to the Lie–Bäcklund operator

$$Q_1 = \left(u_t + u_{xxx} - 3\frac{u_{xx}u_x}{u} + \alpha(t)u\right)\partial_u, \tag{17}$$

where $\alpha(t)$ is a function of t.

We have proved that the equation (16) admits the operator (17) if and only if f satisfies the Korteweg–de Vries equation in the form

$$f_t + f_{xxx} - 6ff_x = 0. \tag{18}$$

This statement is valid for arbitrary smooth $\alpha(t)$. Thus if one can construct the general solution of equation (16) for some solution $f(t,x)$ of (18) then the corresponding ansatz will reduce the partial differential equation

$$u_t + u_{xxx} - 3\frac{u_{xx}u_x}{u} + \alpha(t)u = 0 \tag{19}$$

to the system of two ordinary differential equations with independent variable t. We stress that a solution $f(t,x)$ should not necessarily vanish at the infinity.

To solve the Cauchy problem

$$u|_{t=t_0} = g(x) \tag{20}$$

for equation (19) one should construct the solution $f = p(t,x)$ of equation (18) satisfying the condition $p(t_0,x) = \frac{g_{xx}}{g}$ and then to integrate the ordinary differential equation

$$u_{xx} = p(t,x)u.$$

If we can construct the ansatz in this way then we reduce the Cauchy problem (20) for the equation (19) to the Cauchy problem for the system of two ordinary differential equations.

In addition note that Theorem 1 helped us to generalize the theorem proved in [8] concerning the sufficient conditions for the solution obtained by using conditional symmetry operators to be an invariant solution in the classical sense. Namely consider involutive family of operators

$$Q_a = \sum_{j=1}^{n} \xi_{aj}(x,u)\partial_{x_j} + \eta_a(x,u)\partial_u, \qquad a = \overline{1,m}. \tag{21}$$

Suppose that the equation (1) is conditionally invariant with respect to involutive family of operators (21) and corresponding ansatz reduces this equation to an ordinary differential equation of k_1-th order. Then the following statement holds.

Theorem 2. *Let equation* (1) *be invariant with respect to s-dimensional Lie algebra* AG_s *and conditionally invariant with respect to involutive family of operators* $\{Q_i\}$. *If the system*

$$\sum_{l=1}^{n} \xi_i^l \frac{\partial u}{\partial x_l} = \eta_i(x,u)$$

is also invariant under the algebra AG_s *and* $s \geq k_1 + 1$, *then conditionally invariant solution of equation* (1) *with respect to involutive family of operators* $\{Q_i\}$ *is an invariant solution in the classical Lie sense.*

It is necessary to note that this theorem can be generalized to the case when the algebra AG_m contains Lie–Bäcklund operators too.

3 Conclusion

We showed that the symmetry of ordinary differential equations can be used for reduction of partial differential equations to a system with fewer number of independent variables. It follows from Theorem 1 that the linearity is not a necessary condition for this reduction. Thus the restriction obtained in [4] on the dimension of vector space W_k: $k \leq 2p+1$, where p is the order of studied evolution equation, is not valid in this case. It is obvious that the suggested method is applicable in a multi-dimensional case.

In addition note that this approach can be used in solving the problem of integrability of a partial differential equations. It gives the possibility to reduce this problem to the problem of integrability for an ordinary differential equation. We consider this method to be important in studying quasi-exactly solvable systems.

We also obtained the generalized sufficient condition for the solution constructed by using conditional symmetry to be an invariant one in classical sense.

Combination of non-point and conditional symmetries of the evolution-type equations for construction of its exact solutions are presented. Also we analyzed discrete symmetries of Maxwell equations in vacuum and decoupled ones to the four independent equations that can be solved independently.

1 Introduction

Generalization of Lie classical approach to non-Lie approach that take into consideration conditional symmetries, non-point symmetries, supersymmetries, parasupersymmetries, discrete symmetries opens us additional ways of investigation of partial differential equations (PDEs). For instance, it is possible to seek invariance algebra of DE in a class of high-order differential operators or even of integro-differential operators. In this paper we consider two possibilities for expansion of applications of symmetries to (PDEs) by using non-point symmetries and discrete symmetries. First we consider a problem of construction of ansatzes not for the dependent variable $u(t,x)$ (as it usually used by non-classical method, by method of nonlinear separation and by method of generalized symmetry) but for its *derivatives*:

$$\frac{\partial u}{\partial t} = R_1(t,x,u,\varphi_1(\omega),\varphi_2(\omega)),$$
$$\frac{\partial u}{\partial x} = R_2(t,x,u,\varphi_1(\omega),\varphi_2(\omega)), \qquad \omega = \omega(t,x),$$

that reduce our evolution equation (F is an arbitrary smooth function)

$$u_t = F(u_{xx}) \tag{1}$$

to a system of two DE for function $\varphi_1(\omega)$ and $\varphi_2(\omega)$. The main idea we exploit here is to find symmetries of the system of equations

$$v_1^2 = v_2^1,$$
$$v_2^2 = \Phi\big(v^1\big), \qquad \Phi = F^{-1}, \qquad v^1 \equiv \frac{\partial u}{\partial t}, \qquad v^2 \equiv \frac{\partial u}{\partial x}, \tag{2}$$

(lower indices designate the respect derivatives, i.e., $v_2^1 = \frac{\partial v^1}{\partial x_2}$, $v_1^2 = \frac{\partial v^2}{\partial x_1}$ and $x_1 \equiv t$, $x_2 \equiv x$) corresponding to (1) instead of symmetries of initial equation (1). Taking into account the above

designations, it is evident that second equation of system (2) corresponds to (1), and the first one is the compatibility condition. More detailed explanation that (1) yields system (2) see in [1–3].

We note that by investigating the symmetry properties of system (2) we can find symmetry operators that would not correspond to any infinitesimal operators of group of point transformations of (1) and thus we can extend the class of symmetry operators of (1).

Another goal of our paper is to show an effective way of simplifying a given problem using discrete symmetries of DE. A successful using of discrete symmetries for investigation of PDE can be found in [5–9].

2 Symmetry classification of evolution equation

Here we investigate the system of (2) and find the maximal invariance algebra of the system. We prove that

Theorem 1. *System* (2) *is invariant with respect to a local Lie algebra generated by operator* ($\xi^1_{v_1}$, $\xi^1_{v_2}$, $\xi^2_{v_1}$, $\xi^2_{v_2}$ *are not equal to zero simultaneously):*

$$X = \xi^1(x_1, x_2, v_1, v_2)\frac{\partial}{\partial x_1} + \xi^2(x_1, x_2, v_1, v_2)\frac{\partial}{\partial x_2} + \eta^1(x_1, x_2, v_1, v_2)\frac{\partial}{\partial v^1} + \eta^2(x_1, x_2, v_1, v_2)\frac{\partial}{\partial v^2},$$

if function $\Phi(v^1)$ *is a solution of equation:*

$$a(\Phi_{v^1}v^1)_{v^1} = b\Phi\Phi_{v^1} + c\Phi_{v^1v^1} + d\Phi_{v^1}, \tag{3}$$

where a, b, c, d *are arbitrary real constants and* $\Phi_{v^1} \equiv \frac{d\Phi}{dv^1}$, $\Phi_{v^1v^1} \equiv \frac{d^2\Phi}{dv_1^2}$.

We notice that Theorem 1 defines us a class of equations (1) admitting Lie symmetries. Fixing values of a, b, c, d in (3) we find various explicit form of $\Phi\big(v^1\big)$. We consider only such forms of $\Phi\big(v^1\big)$ that cannot be transformed to each other by point transformations of equivalence of (1).

Theorem 2. *The maximal invariance algebra of system* (2) *is a 5-dimensional Lie algebra:*

1. $\langle P_1, P_2, P_3, D_1, Q_1\rangle$ *if* $\Phi = \dfrac{1}{\alpha \ln v^1}$, $\alpha = \text{const}$;
2. $\langle P_1, P_2, P_3, D_1, Q_2\rangle$ *if* $\Phi = \dfrac{1}{e^{v^1} - c}$, $c = \text{const}$;
3. $\langle P_1, P_2, P_3, D_1, Q_3\rangle$ *if* $\Phi = \dfrac{1}{1 - \big(v^1\big)^r}$, $r \in \mathbb{R},\ r \neq 0, \pm 1$;
4. $\langle P_1, P_2, P_3, D_1, Q_4\rangle$ *if* $\Phi = \tan v^1$;
5. $\langle P_1, P_2, P_3, D_1, Q_5\rangle$ *if* $\Phi = \tan\big(\alpha \ln v^1\big)$, $\alpha = \text{const}$.

Theorem 3. *The maximal invariance algebra of system* (2) *is a 7-dimensional Lie algebra:*

$$\langle P_1, P_2, P_4, P_5, D_2, Q_7, Q_8\rangle \quad \textit{if} \quad \Phi = \frac{1}{1 - (v^1)^{-3}}$$

(it is a particular case of 3 from Theorem 2 when $r = -3$*).*

Theorem 4. *The maximal invariance algebra of system* (2) *is an infinite-dimensional Lie algebra:*

$$\langle P_1, P_2, P_3, D_1, Q_6\rangle \quad \textit{if} \quad \Phi = \frac{1}{v^1}.$$

The basis elements of the Lie algebras have the following form:

$$P_1=\frac{\partial}{\partial x_1},\quad P_2=\frac{\partial}{\partial x_2},\quad P_3=\frac{\partial}{\partial v^2},\quad P_4=x_2\frac{\partial}{\partial x_3}+\frac{\partial}{\partial v^2},\quad P_5=\frac{\partial}{\partial x_3},$$
$$D_1=2x_1\frac{\partial}{\partial x_1}+x_2\frac{\partial}{\partial x_2}+v^2\frac{\partial}{\partial v^2},\quad D_2=2x_1\frac{\partial}{\partial x_1}+x_2\frac{\partial}{\partial x_2}+2x_3\frac{\partial}{\partial x_3}+v^2\frac{\partial}{\partial v^2},$$
$$Q_1=-x_1\frac{\partial}{\partial x_1}+v^2\frac{\partial}{\partial x_2}+v^1\frac{\partial}{\partial v^1},\quad Q_2=\big(x_2+2cv^2\big)\frac{\partial}{\partial x_2}+2\frac{\partial}{\partial v^1}-v^2\frac{\partial}{\partial v^2},$$
$$Q_3=-(r+1)x_1\frac{\partial}{\partial x_1}-rv^2\frac{\partial}{\partial x_2}+v^1\frac{\partial}{\partial v^1}-rv^2\frac{\partial}{\partial v^2},$$
$$Q_4=-2v^2\frac{\partial}{\partial x_2}+2\frac{\partial}{\partial v^1}+2x_2\frac{\partial}{\partial v^2},\quad Q_5=-x_1\frac{\partial}{\partial x_1}-\alpha v^2\frac{\partial}{\partial x_2}+v^1\frac{\partial}{\partial v^1}+\alpha x_2\frac{\partial}{\partial v^2},$$
$$Q_6=-B_{v^2}\frac{\partial}{\partial x_2}+B_{x_1}\frac{\partial}{\partial v^1},$$
$$Q_7=2x_1\frac{\partial}{\partial x_1}+3v^2\frac{\partial}{\partial x_2}+\left[\frac{3}{2}\big(v^2\big)^2+3x_3\right]\frac{\partial}{\partial x_3}+v^1\frac{\partial}{\partial v^1}+3v^2\frac{\partial}{\partial v^2},$$
$$Q_8=\big[3\big(v^2\big)^2-2x_3\big]\frac{\partial}{\partial x_2}+2\big(v^2\big)^3\frac{\partial}{\partial x_3}++2v^1v^2\frac{\partial}{\partial v^1}+2(v^2)^2\frac{\partial}{\partial v^2},$$

where $B\big(x_1,v^2\big)$ is an arbitrary solution of equation:

$$B_{v^2v^2}+B_{x_1}=0$$

(we designate $B_{x_1}\equiv\frac{\partial B}{\partial x_1}$, $B_{v^2v^2}\equiv\frac{\partial^2 B}{\partial v^2\partial v^2}$, ...).

The Theorems are proved by means of the Lie algorithm [11, 12]. It is worth noting that operators Q_a ($a=\overline{1,8}$) correspond to non-point symmetry operators of (1). The cases 4 and 5 of Theorem 2 have been obtained under classical symmetry investigation in [13] and under studying of potential symmetries in [14].

3 Ansätze and exact solutions

Let us use operators of non-point symmetries Q_a, $a=\overline{1,8}$ for reducing of (2) to a system of two ordinary differential equations. It is obvious that we can use also the first prolongation operators of point symmetry of (1). In order to construct an ansatz reducing given equation to system of two ordinary DEs we should use two-dimensional subalgebra of invariance algebra of equation. At the same time according to [15] the obtained solution will be an invariant solution in the Lie sense and can be obtained by classical Lie method. It follows that we should use operators of non-point symmetries to obtain new results.

We note that (1) connected with nonlinear heat equation:

$$\chi_t+(C(\chi)\chi_x)_x=0, \tag{4}$$

Indeed, by double differentiation of (1) with respect to x we obtain equation (4), where $\chi=u_{xx}$, $C(\chi)=F'(\chi)$.

Thus, it is possible to find exact solutions for function χ instead of function u. The ansatz

$$v^1=\frac{\varphi_1\big(v^2\big)}{x_1},\qquad v^2=\frac{x_2}{\varphi_2\big(v^2\big)-\ln x_1}$$

constructed by the operator Q_1 reduces system (2) to the following ordinary differential equations ($\alpha=1$):

$$\frac{d\varphi_1}{dv^2}=v^2,\qquad \ln\varphi_1-\varphi_2=v^2\frac{d\varphi_2}{dv^2}.$$

Integrating the latter system we find exact solution of (4) (when $C(\chi) = -\frac{1}{\chi^2}\exp\left(\frac{1}{\chi}\right)$) in the form:

$$\exp\left(\frac{1}{\chi}\right) = \frac{\theta^2+c}{2t}, \qquad \theta = \frac{x}{\ln\frac{\theta^2+c}{2te^2} + \frac{2\sqrt{c}}{\theta}\arctan\frac{\theta}{\sqrt{c}} + \frac{c_1}{\theta}}, \quad \text{if} \quad c>0;$$

$$\exp\left(\frac{1}{\chi}\right) = \frac{\theta^2+c}{2t}, \qquad \theta = \frac{x}{\ln\frac{\theta^2+c}{2te^2} + \frac{\sqrt{-c}}{\theta}\ln\left|\frac{\theta-\sqrt{-c}}{\theta+\sqrt{-c}}\right| + \frac{c_1}{\theta}}, \quad \text{if} \quad c<0,$$

c, c_1 are constants, $\theta \equiv v^2$. In an analogous way we can find exact solutions for the other cases listed in Theorem 2. Here we represent operators, corresponding ansatzes and reduced systems of ODEs:

Operator	Ansätze	Reduced system
Q_1+P_3	$v^1 = \frac{\varphi_1(\omega)}{x_1}$ $v^2 = \varphi_2(\omega) - \ln x_1$ $\omega = x_2 - \frac{(v^2)^2}{2}$	$\frac{d\varphi_1}{d\omega} = -1$ $(\ln\varphi_1 - \varphi_2)\frac{d\varphi_2}{d\omega} = 1$
Q_1+D_1	$v^1 = x_1\varphi_1(\omega)$ $v^2 = x_1\varphi_2(\omega)$ $\omega = \frac{x_2}{v^2} - \ln v^2$	$\frac{d\varphi_1}{d\omega} = {\varphi_2}^2$ $\varphi_2 + \left(1+\omega+\ln\frac{\varphi_2}{\varphi_1}\right)\frac{d\varphi_2}{d\omega} = 0$
Q_2-D_1	$v^1 = \varphi_1(\omega) - \ln(x_1\varphi_2(\omega))$ $v^2 = x_1\varphi_2(\omega)$ $\omega = x_2 + c(v^2)^2$	$\exp(\varphi_1)\frac{d\varphi_1}{d\omega} = \varphi_2$ $\varphi_2\frac{d\varphi_1}{d\omega} - \frac{d\varphi_2}{d\omega} = {\varphi_2}^2$
Q_3	$v^1 = x_1^{\frac{-1}{(r+1)}}\varphi_1(\omega)$ $v^2 = x_1^{\frac{r}{r+1}}\varphi_2(\omega)$ $\omega = x_2 - v^2$	$\frac{r+1}{r}\varphi_2 = \frac{d\varphi_1}{d\omega}$ $\varphi_1^r\frac{d\varphi_2}{d\omega} = -1$
Q_3+rD_1	$v^1 = x_1^{\frac{1}{(r-1)}}\varphi_1(v^2)$ $v^2 = x_2 - x_1^{\frac{r}{r-1}}\varphi_2(v^2)$	$\frac{r}{1-r}\varphi_2 = \frac{d\varphi_1}{dv^2}$ $\varphi_1^{-r}\frac{d\varphi_2}{dv^2} = -1$
Q_4	$v^1 = \varphi_2(x_1) - \arcsin\frac{x_2}{\sqrt{\varphi_1(x_1)}}$ $v^2 = \sqrt{\varphi_1(x_1) - x_2^2}$	$\frac{d\varphi_1}{dx_1} = -2$ $\tan\varphi_2 = 0$
Q_5	$v^1 = \frac{\varphi_1(\omega)}{x_1}$ $v^2 = \sqrt{\varphi_2(\omega) - x_2^2}$ $\omega = \ln x_1 - \arcsin\frac{x_2}{\sqrt{\varphi_2}}$	$\frac{d\varphi_1}{d\omega} = \frac{1}{2}\frac{d\varphi_2}{d\omega}$ $\frac{d\varphi_2}{d\omega} = \frac{2\tan\{\ln(\varphi_1-\omega)\}\varphi_2}{1-\tan\{\ln(\varphi_1-\omega)\}}$

We stress that the obtained ansatzes cannot be found by classical point symmetries.

4 Discrete symmetries of Maxwell equations

Let us consider the Maxwell equations for vacuum in Dirac form [4]:

$$L\Psi = (p_0 - \vec{\alpha}\vec{p})\Psi = 0 \tag{5}$$

where Ψ is a 4-component function:

$$\Psi = \begin{pmatrix} 0 \\ E_1 - iH_1 \\ E_2 - iH_2 \\ E_3 - iH_3 \\ E_4 - iH_4 \end{pmatrix}, \qquad \alpha_a\alpha_b + \alpha_b\alpha_a = 2\delta_{ab}$$

Equation 5 admits the following operators of discrete symmetry (ODS):

$$Q_1 = \alpha_1 R_{23}, \qquad Q_2 = \alpha_2 R_{13}, \qquad Q_3 = \alpha_3 R_{12}, \qquad Q_4 = CT$$

(where R_{ab}: $x_a \to -x_a$, $x_b \to -x_b$, $a \neq b$, $a, b = 1, 2, 3$, C is operator of complex conjugation, T is operator of time inversion) as much as the invariance condition $[L, Q]\,\Psi = 0$ holds.

It is easy to verify that these ODS satisfy the following commutation relations ($a = 1, 2, 3$):

$$[Q_1, Q_2] = 2iQ_3, \qquad [Q_1, Q_3] = 2iQ_2, \qquad [Q_2, Q_3] = 2iQ_1, \qquad [Q_a, Q_4] = 0$$

and form $AO(3) \oplus Q_4$ algebra. Finding the diagonalizing operators for Q_1 and Q_2 we reduce the equation (5) to four independent one-component equations. Diagonalizing operator of Q_1 has the form:

$$U = U_1 U_2 U_3, \qquad U_1 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \qquad U_1^{-1} = \begin{pmatrix} 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

$$U_2 = \frac{(1 + i\sigma_1)}{\sqrt{2}} \otimes I_2, \qquad U_2^{-1} = \frac{(1 - i\sigma_1)}{\sqrt{2}} \otimes I_2,$$

$$U_3 = \left(R_+^{23} + i\alpha_2 R_-^{23}\right), \qquad U_3^{-1} = \left(R_+^{23} - i\alpha_2 R_-^{23}\right), \qquad R_\pm^{23} = \frac{1 \pm R_{23}}{2}, \qquad \Psi' = U\Psi.$$

Thus the corresponding reducing equation has the form:

$$L'\Psi' = U_1 U_2 U_3 L U_3^{-1} U_2^{-1} U_1^{-1} \Psi' = \{p_0 - ip_2 R_{23} \mp p_1 R_{23} \pm p_3\}\Psi' = 0.$$

In a similar way we find that the diagonalizing operator of Q_2

$$U = U_1 U_2, \quad U_1 = \frac{1}{2}\begin{pmatrix} i & i & 1 & 1 \\ -1 & 1 & i & -i \\ -1 & -1 & -i & -i \\ i & -i & -1 & 1 \end{pmatrix}, \qquad U_1^{-1} = \frac{1}{2}\begin{pmatrix} -i & -1 & -1 & -i \\ -i & 1 & -1 & i \\ 1 & -i & i & -1 \\ 1 & i & i & 1 \end{pmatrix},$$

$$U_2 = (R_+ + i\alpha_1 R_-), \qquad U_2^{-1} = (R_+ - i\alpha_1 R_-)$$

reduces the corresponding equation (5) to the following uncoupled equations:

$$L'\Psi' = U_1 U_2 L U_2^{-1} U_1^{-1} \Psi' = \{p_0 - ip_1 R_{13} \mp p_2 R_{13} \mp p_3\}\Psi' = 0.$$

5 Conclusion

We have shown how we can use non-Lie symmetries (discrete, conditional and non-point ones) for reducing a given problem to a simpler one and to construct its exact solutions. It enabled us to find new classes of nonlinear heat equations for which the reduction method can be successfully applied. With our symmetries equation (1) can be reduced to system of ODEs. We are then able to derive the exact solutions of the heat equation (4) with nonlinearities:

$$C_1(\chi) = -\frac{2}{\chi^5}\exp\left(\frac{1}{\chi}\right), \qquad C_2(\chi) = \frac{1}{\chi(C\chi + 1)}, \quad C = \text{const},$$

$$C_3(\chi) = \frac{1}{r}\left\{\frac{(\chi - 1)^{(1-r)/r}}{\chi^{\frac{2+r}{r}}}\right\}, \qquad C_4(\chi) = \frac{1}{1 + \chi^2}, \qquad C_5(\chi) = \frac{\arctan\chi \exp(\arctan\chi)}{1 + \chi^2}.$$

As far as we know, this is the first application of the non-point and conditional symmetries of an evolution equation for construction its exact solutions. In our opinion using of generalized conditional symmetry in the proposed approach is very promising. It would be interesting to develop this technique for searching exact solutions of DEs with supersymmetries and extended supersymmetries.

Thus extending of symmetry ideas (non-point symmetry, conditional symmetry, supersymmetry) enables us to obtain new results which are important from both mathematical and physical point of view.

In the present paper we consider a class of inhomogeneous Burgers equations. Nonlocal transformations of a dependent variable that establish relations between various equations of this class were constructed. We identified the subclass of the equations, invariant under the appropriate substitution. The formula of non-local superposition for the inhomogeneous Burgers equation was constructed. We also present examples of generation of solutions.

1 Non-local invariance of the inhomogeneous Burgers equation

Let us consider an inhomogeneous Burgers equation:

$$u_t + uu_x - u_{xx} = c, \qquad u = u(x,t), \tag{1}$$

where $c = c(x,t)$ is an arbitrary smooth function, and $u_t = \frac{\partial u}{\partial t}$, $u_x = \frac{\partial u}{\partial x}$, $u_{xx} = \frac{\partial^2 u}{\partial x^2}$.

Let us make the first order non-local substitution of the dependent variable:

$$u = f(t,x,v,v_x), \tag{2}$$

where $v = v(x,t)$ is the new dependent variable.

We seek the transformation of the equation (1) into another inhomogeneous Burgers equation:

$$v_t + vv_x - v_{xx} = g, \tag{3}$$

with arbitrary smooth function $g = g(x,t)$. To obtain this transformation we substitute (2) and its differential prolongations into equation (1). For differential prolongations of the equation (3) we obtain the determining relation:

$$\begin{aligned} &f_t - f_v v_x v + f_v g - f_{v_x} v_{xx} v - f_{v_x} {v_x}^2 + f_{v_x} g_x + f f_x + f f_v v_x + f f_{v_x} v_{xx} - f_{xx} \\ &\quad - 2f_{vx} v_x - 2f_{v_x x} v_{xx} - f_{vv} {v_x}^2 - 2v_x f_{vv_x} v_{xx} - f_{v_x v_x} {v_{xx}}^2 - c = 0. \end{aligned}$$

Having split these expressions with respect to the derivative v_{xx}, we obtain the system of equations:

$$\begin{aligned} &f_{v_x v_x} = 0, \\ &-f_{v_x} v + f f_{v_x} - 2f_{vv_x} v_x - 2f_{v_x x} = 0, \\ &f_t - f_v v_x v + f_v g + f f_v v_x - f_{v_x} {v_x}^2 + f_{v_x} g_x + f f_x - c - f_{vv} {v_x}^2 - f_{xx} - 2f_{vx} v_x = 0. \end{aligned} \tag{4}$$

The nontrivial solution of the system (1) is

$$f = \frac{-2v_x + 4F_x + v^2 - 2vF}{v - 2F}, \tag{5}$$

$$c = 2F_{xx} + 2F_t + 4F_xF, \tag{6}$$
$$g = -2F_{xx} + 2F_t + 4F_xF. \tag{7}$$

Here $F = F(x,t)$ is an arbitrary smooth function.

Let us consider a non-local invariance transformation, namely $c = g$. The equations (6), (7) give us the condition $F_{xx} = 0$. Integration yields $F = A(t)x + B(t)$, where $A(t)$ and $B(t)$ are arbitrary smooth functions. So we have found the non-local invariant transformation for the inhomogeneous Burgers equation in a general form:

$$f = \frac{2v_x - 4A - v^2 + 2vAx + 2vB}{-v + 2Ax + 2B}, \tag{8}$$
$$g = c = 2A_tx + 2B_t + 4A^2x + 4AB. \tag{9}$$

Substituting $c = g = 0$ into expressions (6), (7), we find the system:

$$2F_{xx} + 2F_t + 4F_xF = 0,$$
$$-2F_{xx} + 2F_t + 4F_xF = 0.$$

The general and trivial solutions of this system are:

$$F = \frac{x + c_1}{2t + 2c_2}, \qquad F = 0. \tag{10}$$

Here c_1, c_2 are an arbitrary constants. Having substituted (10) into (5), we get the following non-local invariant transformations of the homogeneous Burgers equation for the general and trivial solutions respectively:

$$u = \frac{2v_xt + 2v_xc_2 - 2 - v^2t - v^2c_2 + vx + vc_1}{-vt - vc_2 + x + c_1}, \qquad u = \frac{-2v_x + v^2}{v}.$$

Example 1. Using (5), (6), (7) we transform the inhomogeneous Burgers equation:

$$u_t + uu_x - u_{xx} = 8\frac{\sin x}{\cos^3 x}, \tag{11}$$

into homogeneous one. We obtain the system of the equations for F by substituting $c = 8\frac{\sin x}{\cos^3 x}$ and $g = 0$ in (6), (7):

$$F_t + 2F_xF - F_{xx} = 0,$$
$$F_t + 2F_xF + F_{xx} = 4\frac{\sin x}{\cos^3 x}.$$

There is the general solution of the system $F = \mathrm{tg}x$. It gives us the following substitution:

$$u = \frac{2v_x\cos^2 x - 4 - v^2\cos^2 x + 2v\sin x\cos x}{\cos x(-v\cos x + 2\sin x)}. \tag{12}$$

This expression can be applied to generation of solutions of the equation (11). Thus, the partial solution of the homogeneous Burgers equation:

$$v = \frac{-4x}{2t + x^2}, \tag{13}$$

generates the following solution of the equation (11):

$$u = -2\frac{2\cos^2 x + 2t + x^2 + 2x\sin x\cos x}{\cos x(2x\cos x + 2t\sin x + x^2\sin x)}. \tag{14}$$

Example 2. It is an example of application of the non-local transformation (8) for a partial case of equation (1): $A = 1, B = t$. Then we have the equation:

$$u_t + uu_x - u_{xx} = 4x + 4t + 2, \tag{15}$$

and corresponding invariant transformation:

$$\overset{(2)}{u} = \frac{2\overset{(1)}{u}_x - 4 - \overset{(1)}{u}^2 + 2\overset{(1)}{u}x + 2\overset{(1)}{u}t}{-\overset{(1)}{u} + 2x + 2t}. \tag{16}$$

One of the similarity solutions of the equation (15) (see Appendix 1) is

$$u = -2 - 2x - 2t + e^{2t}\mathrm{tg}\left(\frac{1}{4}(2x + 1 + 2t)\, e^{2t}\right).$$

Having substituted it into (16) we find a new solution of the equation (15):

$$\overset{(2)}{u} = -\frac{(6t + 6x + 4)\,\mathrm{tg}\left(\frac{e^{2t}}{4}(2x + 1 + 2t)\right) e^{2t} - 12 - 8x^2 - 12x - 12t - 8t^2 - 16xt}{-2 - 4x - 4t + e^{2t}\mathrm{tg}\left(\frac{e^{2t}}{4}(2x + 1 + 2t)\right)}.$$

Using this algorithm we get a chain of solutions:

$$\begin{aligned} -2x - 2t - 2 &\to -2\frac{3 + 2x^2 + 4xt + 3x + 2t^2 + 3t}{2x + 2t + 1} \\ &\to -2\frac{4x^3 + 8x^2 + 12x^2t + 12xt^2 + 16xt + 15x + 15t + 4t^3 + 7 + 8t^2}{3 + 4x^2 + 8xt + 4x + 4t^2 + 4t} \to \cdots. \end{aligned}$$

2 Linearization of the inhomogeneous Burgers equation

We are looking for a non-local transformation

$$u = f(v, v_x), \tag{17}$$

of equation (1), where $v = v(x, t)$ is a smooth function, which yields equation:

$$v_t - v_{xx} + \varphi = 0. \tag{18}$$

Here $\varphi = \varphi(x, t, v)$ is an arbitrary smooth function. To obtain this transformation we substitute (17) and its differential prolongations into equation (1). For differential prolongations of the equation (18) we obtain the determining correlation:

$$f_v\varphi + f_{v_x}\varphi_x + f_{v_x}\varphi_v v_x + ff_v v_x + ff_{v_x}v_{xx} - f_{vv}{v_x}^2 - 2v_x f_{vv_x}v_{xx} - f_{v_xv_x}{v_{xx}}^2 + c = 0.$$

Having split these expressions with respect to the derivative v_{xx}, we obtain the system of equations:

$$\begin{aligned} &f_{v_xv_x} = 0, \\ &2f_{vv_x}v_x - ff_{v_x} = 0, \\ &f_v\varphi + f_{v_x}\varphi_x + f_{v_x}\varphi_v v_x + ff_v v_x + c - f_{vv}{v_x}^2 = 0. \end{aligned}$$

The nontrivial solution is

$$f = -2\frac{v_x}{v + c_1}, \tag{19}$$

$$c = -2F_x, \tag{20}$$
$$\varphi = -F(v + c_1). \tag{21}$$

Here c_1 is an arbitrary constant and $F = F(x,t)$ is an arbitrary smooth function. Thus we obtain the Cole–Hopf substitution with the parameter c_1.

$$u = -2\frac{v_x}{v + c_1}. \tag{22}$$

So the inhomogeneous Burgers equation may be transformed into the linear equation with variable coefficients [2, 4]:

$$v_t - F(v + c_1) - v_{xx} = 0.$$

Here the function F is obtained from the equation (20). In the case $c_1 = 0$, we obtain the transformation into the homogeneous equation:

$$v_t - Fv - v_{xx} = 0. \tag{23}$$

Theorem 1. *Formula of a nonlinear superposition for inhomogeneous Burgers equation can be written in the following way:*

$$\begin{aligned} &\overset{(3)}{u} = -2\partial_x \ln\left(\overset{(1)}{\tau} + \overset{(2)}{\tau}\right), \\ &-2\partial_x \ln \overset{(k)}{\tau} = \overset{(k)}{u}, \qquad k = 1, 2, \\ &-2\partial_t \ln \overset{(k)}{\tau} = \overset{(k)}{u}_x - \frac{1}{2}\overset{(k)}{u}^2 + \psi, \qquad \psi_x = c(x,t) \end{aligned} \tag{24}$$

Here $\overset{(1)}{u}$, $\overset{(2)}{u}$ *are known solutions, and* $\overset{(3)}{u}$ *is the new one.*

Proof. Let $\overset{(1)}{\tau}$, $\overset{(2)}{\tau}$ be solutions of equation (23). Then $\overset{(3)}{\tau} = \overset{(1)}{\tau} + \overset{(2)}{\tau}$ is a new solution of equation (23). By using the substitution $u = -2\partial_x \ln(\tau)$ we can find $\overset{(3)}{u}$:

$$\overset{(3)}{u} = -2\partial_x \ln\left(\overset{(3)}{\tau}\right) = -2\partial_x \ln\left(\overset{(1)}{\tau} + \overset{(2)}{\tau}\right).$$

On the other side $\overset{(k)}{\tau}$, $k = 1, 2$ are connected with $\overset{(k)}{u}$, $k = 1, 2$ in the following way:

$$-2\partial_x \ln \overset{(k)}{\tau} = \overset{(k)}{u}, \qquad -2\partial_t \ln \overset{(k)}{\tau} = \overset{(k)}{u}_x - \frac{1}{2}\overset{(k)}{u}^2 + \psi, \qquad \psi_x = c(x,t), \qquad k = 1, 2.$$

So superposition formula (24) is obtained. ■

Example 3. We can use superposition formula for equation (15). There are two solutions of equation (15):

$$\begin{aligned} &\overset{(1)}{u} = -2 - 2x - 2t + e^{2t}\mathrm{tg}\left(\frac{1}{4}(2x + 1 + 2t)e^{2t}\right), \\ &\overset{(2)}{u} = -2x - 2t - 2, \end{aligned}$$

The formula (24) gives us a third one:

$$\overset{(3)}{u} = -2 - 2x - 2t + \frac{\mathrm{tg}\left(\left(\frac{x}{2} + \frac{1}{4} + \frac{t}{2}\right)e^{2t}\right)e^{2t}}{1 + e^{\frac{e^{4t}}{16}}\sec^2\left(\left(\frac{x}{2} + \frac{1}{4} + \frac{t}{2}\right)e^{2t}\right)}.$$

3 Lie symmetries for the inhomogeneous Burgers equation

To apply the classical method [3] to (1) we require the infinitesimal operator to be of this form:

$$X = \xi_0(x,t,u)\partial_t + \xi_1(x,t,u)\partial_x + \eta(x,t,u)\partial_u.$$

The invariance condition for equation (1) yields an overdetermined system of differential equations for the coordinates of X. Having solved the system of equations we obtain the following expressions for infinitesimals and function $c(x,t)$:

$$\begin{aligned}
&\xi_0 = F_1, \qquad \xi_1 = \frac{1}{2}F_1' x + F_2, \qquad \eta = -\frac{1}{2}uF_1' + \frac{1}{2}F_1'' x + F_2',\\
&c = \left(\frac{1}{2}\int F_1''' F_1 \int F_2 F_1^{-3/2} dt dt - \frac{1}{2}\int F_1''' F_1 dt \int F_2 F_1^{-3/2} dt\right.\\
&\qquad \left. + \int F_1^{1/2} F_2'' dt + F_3(\omega)\right) F_1^{-3/2} + \frac{x}{2}\int F_1''' F_1 dt F_1^{-2},\\
&\omega = \left(x - F_1^{1/2}\int F_2 F_1^{-3/2} dt\right) F_1^{-1/2}.
\end{aligned}$$

Here $F_1 = F_1(t)$, $F_2 = F_2(t)$, $F_3 = F_3(\omega)$ are arbitrary smooth functions. If $F_1 = 0$ we have:

$$c = \frac{F_2'' x}{F_2} + F_3,$$

Obviously, the connection between the right hand side of the equation (1) and its Lie symmetries exists.

Symmetry Analysis of (2 + 1)-Dimensional Doebner–Goldin Equations

Jörg VOLKMANN and Gerd BAUMANN

Department of Mathematical Physics, University of Ulm,
Albert–Einstein–Allee 11, D–89069 Ulm/Donau, Germany
E-mail: *volk@physik.uni-ulm.de, gerd.baumann@physik.uni-ulm.de*

The paper discusses the application of *MathLie* in connection with Lie group analysis. The examined example is the (2 + 1)-dimensional case of the Doebner–Goldin equations after Madelung representation. The related Lie algebras are calculated and classified. Furthermore we discuss the determination of an optimal system for the 7-dimensional case of one Lie algebra.

1 Introduction

The application of Lie's theory to examine systems of partial differential equations is one of the most efficient methods to calculate solutions for equations of motions. Furthermore Lie's theory allows the classification of solutions and related algebras. One can use Lie's transformation theory as a microscope to get information about the properties of a physical model [1, 2]. Lie's method is discussed in literature in great detail [3–6]. With the algorithms at hand one can generate computer programs such as *MathLie* to automatically carry out the calculations. Today there are a large number of symbolic computing programs for the algebraic manipulation of equations.

In this discussion we show investigations to get information about the structure of solutions of the Doebner–Goldin–Madelung equations. The symmetry investigations of these equations are carried out by using the Mathematica program *MathLie*. Section 3 is concerned with the algebra investigation of a 7-dimensional algebra using the *Mathematica* program *MathLieAlg* by R. Schmid [7]. Section 4 deals with an algorithm of calculating optimal systems. The example discussed in Section 4 is a 7-dimensional algebra generated by one of the Doebner–Goldin–Madelung equation.

2 Derivation of the Doebner–Goldin equations

The investigation of Borel quantization for S^1 leads to a non-linear Schrödinger equation of the form (here with $m = 1$, $\hbar = 1$):

$$\mathrm{i}\partial_t\psi = -\frac{1}{2}\Delta\psi + V(\vec{x},t)\psi + \frac{\mathrm{i}}{2}KR_2(\psi)\psi + \sum_{j=1}^{5} D_jR_j(\psi)\psi, \tag{1}$$

derived by Dobrev, Doebner and Twarock [8] and nowadays called Doebner–Goldin equations. Here, the $R_j(\psi)$ with $j \in \{1,\ldots,5\}$ are real valued functionals of the real valued density $\varrho = \overline{\varrho} = \psi\overline{\psi}$ and the real valued current $\vec{j} = \overline{\vec{j}} = \frac{\mathrm{i}\hbar}{2m}\left(\psi\nabla\overline{\psi} - \overline{\psi}\nabla\psi\right)$ and can be found in [8, 9].

In the following we consider the (2+1)-dimensional case of equation (1) without potential V. Applying the Madelung transformation

$$\psi \to \sqrt{\varrho(\vec{x},t)}\exp\left(\mathrm{i}S(\vec{x},t)\right), \qquad \overline{\psi} \to \sqrt{\varrho(\vec{x},t)}\exp\left(-\mathrm{i}S(\vec{x},t)\right)$$

to equation (1) and dividing the resulting equations into real and imaginary parts we find the following system:

$$\varrho_t + S_x\varrho_x + S_y\varrho_y + \varrho S_{xx} + \varrho S_{yy} - \delta\varrho_{xx} - \delta\varrho_{yy} = 0, \tag{2}$$

$$(1+8D_5)\big(\varrho_x^2+\varrho_y^2\big) + 4\varrho^2\big(2S_t + S_x^2 + 2D_3S_x^2 + (1+2D_3)S_y^2 + 2D_1S_{xx} + 2D_1S_{yy}\big) \tag{3}$$
$$+ 2\varrho(4D_1S_x\varrho_x + 4D_4S_x\varrho_x + 4(D_1+D_4)S_y\varrho_y - \varrho_{xx} + 4D_2\varrho_{xx} + (-1+4D_2)\varrho_{yy}) = 0,$$

where $m = 1$ and $\hbar = 1$. Here, D_1, D_2, D_3, D_4, and δ are real valued parameters. By permutating these parameters we receive 63 different model equations (see table in [9]) of nonlinear Schrödinger type. This set of equations is called the set of Doebner–Goldin–Madelung equations. The whole set of equations are examined with the Mathematica program *MathLie*.

3 Symmetry analysis of the (2 + 1)-dimensional Doebner–Goldin–Madelung equations

In order to find the symmetry group of equations (2), (3), we apply the algorithms described in text books such as [3, 1]. We look for an algebra of vector fields of the form

$$V = \xi[1]\partial_x + \xi[2]\partial_t + \phi[1]\partial_\varrho + \phi[2]\partial_S,$$

where the infinitesimals $\xi[1]$, $\xi[2]$ and $\phi[1]$, $\phi[2]$ depend on x, t, ϱ, and S in general.

These coefficients are determined from the requirement that the second prolongation of V should annihilate the equation on the solution set of the equation. This was done by using the Mathematica program *MathLie* [3] for all 63 model equations of the Doebner–Goldin–Madelung equations.

The next step of our discussion is related to the investigation of the 7-dimensional algebra of the equation with the parameters D_3, D_5 (see [9]). We use a *Mathematica* program *MathLieAlg* by R. Schmid [7]. The generators of this equation are:

$$V[1] = \partial_t, \qquad V[2] = \varrho\partial_\varrho, \qquad V[3] = -4t\partial_t - 2x\partial_x - 2y\partial_y,$$
$$V[4] = \partial_x, \qquad V[5] = \partial_S, \qquad V[6] = -y\partial_x + x\partial_y, \qquad V[7] = \partial_y. \tag{4}$$

The only non-zero commutators of the vector fields are following:

$$[V[1],V[3]] = -4V[1], \qquad [V[3],V[4]] = 2V[4], \qquad [V[3],V[7]] = 2V[7],$$
$$[V[4],V[6]] = V[7], \qquad [V[6],V[7]] = V[4].$$

Nontrivial algebra elements are $\{V[1],V[2],V[3],V[5],V[6]\}$. Algebras can be generated by the following sets:

$$\{V[1],V[2],V[3],V[4],V[5],V[6]\}, \qquad \{V[1],V[2],V[3],V[5],V[6],V[7]\},$$
$$\{V[1],V[2],V[3],V[4],V[5],V[6],V[7]\}.$$

The Cartan metric of this algebra reads:

$$\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 24 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

The algebraic properties are following: not semisimple, solvable, not nilpotent.

From this algebra the subalgebras listed in Table 1 can be derived:

Table 1. Table of subalgebras[1].

Dimension	Number of subalgebras	Subalgebra elements
0	1	$\{\}$
1	7	$\{V[1]\},\{V[2]\},\{V[3]\},\{V[4]\},\{V[5]\},\{V[6]\},\{V[7]\}$
2	19	$\{V[1],V[2]\},\{V[1],V[3]\},\{V[1],V[4]\},\{V[1],V[5]\},\{V[1],V[6]\},$ $\{V[1],V[7]\},\{V[2],V[3]\},\{V[2],V[4]\},\{V[2],V[5]\},\{V[2],V[6]\},$ $\{V[2],V[7]\},\{V[3],V[4]\},\{V[3],V[5]\},\{V[3],V[6]\},\{V[3],V[7]\},$ $\{V[4],V[5]\},\{V[4],V[7]\},\{V[5],V[6]\},\{V[5],V[7]\}$
3	27	$\{V[1],V[2],V[3]\},\{V[1],V[2],V[4]\},\{V[1],V[2],V[5]\},\{V[1],V[2],V[6]\},$ $\{V[1],V[2],V[7]\},\{V[1],V[3],V[4]\},\{V[1],V[3],V[5]\},\{V[1],V[3],V[6]\},$ $\{V[1],V[3],V[7]\},\{V[1],V[4],V[5]\},\{V[1],V[4],V[7]\},\{V[1],V[5],V[6]\},$ $\{V[1],V[5],V[7]\},\{V[2],V[3],V[4]\},\{V[2],V[3],V[5]\},\{V[2],V[3],V[6]\},$ $\{V[2],V[3],V[7]\},\{V[2],V[4],V[5]\},\{V[2],V[4],V[7]\},\{V[2],V[5],V[6]\},$ $\{V[2],V[5],V[7]\},\{V[3],V[4],V[5]\},\{V[3],V[4],V[7]\},\{V[3],V[5],V[6]\},$ $\{V[3],V[5],V[7]\},\{V[4],V[5],V[7]\},\{V[4],V[6],V[7]\}$
4	23	$\{V[1],V[2],V[3],V[4]\},\{V[1],V[2],V[3],V[5]\},\{V[1],V[2],V[3],V[6]\},$ $\{V[1],V[2],V[3],V[7]\},\{V[1],V[2],V[4],V[5]\},\{V[1],V[2],V[4],V[7]\},$ $\{V[1],V[2],V[5],V[6]\},\{V[1],V[2],V[5],V[7]\},\{V[1],V[3],V[4],V[5]\},$ $\{V[1],V[3],V[4],V[7]\},\{V[1],V[3],V[5],V[6]\},\{V[1],V[3],V[5],V[7]\},$ $\{V[1],V[4],V[5],V[7]\},\{V[1],V[4],V[6],V[7]\},\{V[2],V[3],V[4],V[5]\},$ $\{V[2],V[3],V[4],V[7]\},\{V[2],V[3],V[5],V[6]\},\{V[2],V[3],V[5],V[7]\},$ $\{V[2],V[4],V[5],V[7]\},\{V[2],V[4],V[6],V[7]\},\{V[3],V[4],V[5],V[7]\},$ $\{V[3],V[4],V[6],V[7]\},\{V[4],V[5],V[6],V[7]\}$
5	13	$\{V[1],V[2],V[3],V[4],V[5]\},\{V[1],V[2],V[3],V[4],V[7]\},\{V[1],V[2],V[3],V[5],V[6]\},$ $\{V[1],V[2],V[3],V[5],V[7]\},\{V[1],V[2],V[4],V[5],V[7]\},\{V[1],V[2],V[4],V[6],V[7]\},$ $\{V[1],V[2],V[3],V[4],V[5]\},\{V[1],V[3],V[4],V[5],V[7]\},\{V[1],V[3],V[4],V[6],V[7]\},$ $\{V[1],V[4],V[5],V[6],V[7]\},\{V[2],V[3],V[4],V[5],V[7]\},\{V[2],V[3],V[4],V[6],V[7]\},$ $\{V[2],V[4],V[5],V[6],V[7]\},\{V[3],V[4],V[5],V[6],V[7]\}$
6	5	$\{V[1],V[2],V[3],V[4],V[5],V[7]\},\{V[1],V[2],V[3],V[4],V[6],V[7]\},$ $\{V[1],V[2],V[4],V[5],V[6],V[7]\},\{V[1],V[3],V[4],V[5],V[6],V[7]\},$ $\{V[2],V[3],V[4],V[5],V[6],V[7]\}$
7	1	$\{V[1],V[2],V[3],V[4],V[5],V[6],V[7]\}$

Examining the subalgebras we can find the ideals listed in [9]. The normalizer of all ideals is the algebra $\{V[1],V[2],V[3],V[4],V[5],V[6],V7]\}$ and the radical reads $\{V[1],V[2],V[3],V[4],V[5],V[6],V7]\}$. For the center we find $\{V[2],V[5]\}$. The adjoint representation of our 7-dimensional algebra can be found in [9].

4 The optimal system of the seven-dimensional algebra

Let us first consider the general system of differential equations

$$F\big(x,u,u^{(n)}\big)=0 \tag{5}$$

and the related symmetry group G. For every s-parametric subgroup H_s one can calculate similarity solutions under the assumption[2], that $s<\min(r,n')$, where n' is the number of independent variables and r is the order of the system of differential equations [4]. In this set of similarity solutions there are such solutions, which can be calculated by a transformation of the symmetry group from other similarity solutions. Our aim is to derive a minimal set of similarity solutions from which one can gain all the other solutions by a transformation. Such a list is called optimal system of similarity solutions with elements which are essentially different types of similarity solutions. The application of the conjugation (see e.g. [12]) and a theorem

[1] $\{\}$ is empty set.

[2] Following [12] the number of parameters s of a subgroup H of a symmetry group G will be written under the symbol of the subgroup.

by Olver [6] allows us to transform the problem of classifying solutions to that of classifying subgroups. The adjoint representation maps this problem to the classification of subalgebras with respect to inner automorphisms. The result is the optimal system of subalgebras. More details can be found in [4, 6].

The literature presents several methods of classifying subalgebras. A detailed discussion of the procedures are given in [10, 4, 5, 11]. A common property of these methods is that they all start with algebras of very low dimension.

Due to Ovsyannikov [13–15] we organize our calculations by the following definition and theorem.

Definition 1 ([15]). An optimal system ΘL is said to be normalized if $\mathrm{Nor}\, K \in \Theta L$ whenever a subalgebra K is in ΘL.

The existence of such optimal system follows from

Theorem 1 ([15]). *For any finite-dimensional Lie algebra there exists a normalized optimal system ΘL of subalgebras.*

The following discussion demonstrates the application of our algorithm [2] to the 7-dimensional algebra 4. We start our calculation with the series of ideals

$$\{\} \subset \{V[1], V[4]\} \subset \{V[1], V[4], V[7]\} \subset \{V[1], V[3], V[4], V[5], V[6], V[7]\}$$
$$\subset \{V[1], V[2], V[3], V[4], V[5], V[6], V[7]\} = L_7$$

and take the maximal Abelian ideal $I_{\max} = \{V[1], V[4], V[7]\}$. The related factor algebra $L_7 \backslash I_{\max}$ is $\{V[2], V[3], V[5], V[6]\}$. Now we are doing the same step with this factor algebra. The series of ideals is

$$0 \subset \{V[2], V[5]\} \subset \{V[2], V[3], V[5], V[6]\}$$

with the maximal Abelian subalgebra $\{V[2], V[5]\}$. The related factor algebra reads $\{V[3], V[6]\}$. By starting with the smallest factoralgebra we have to express a general vector Y by a linear combination of the vectors $V[3]$, $V[6]$:

$$Y_1 = x_3 V[3] + x_6 V[6], \qquad Y_2 = y_3 V[3] + y_6 V[6]. \tag{6}$$

The coefficient matrix of (6) reads $\begin{pmatrix} x_3 & x_6 \\ y_3 & y_6 \end{pmatrix}$ which allows manipulation by row and application of the adjoint representation of the ranks 2, 1, 0. The classification of the above matrix delivers the result in Table 2.

Table 2. Optimal system of the two-dimensional subalgebra $\{V[3], V[6]\}$.

Dimension	Subalgebras
2	$\{V[3], V[6]\}$
1	$\{V[3] + x_6 V[6]\}$, $x_6 \neq 0$, $\{V[3]\}$, $\{V[6]\}$
0	$\{\}$

Now we have to consider the first extension of the algebra. An equation similar to (6) leads to the matrix

$$\begin{pmatrix} u_2 & u_5 & u_3 & u_6 \\ v_2 & v_5 & v_3 & v_6 \\ x_2 & x_5 & x_3 & x_6 \\ y_2 & y_5 & y_3 & y_6 \end{pmatrix} \tag{7}$$

which has to be classified. It allows the ranks 4, 3, 2, 1, 0. In addition there exists a block structure. The 2×2 matrix in the lower right corner with the indices $(3, 6)$ and the matrix in the upper left corner with the indices $(2, 5)$.

We start our calculation with the matrix in the upper left corner related to the indices $(2, 5)$, which allows the ranks 2, 1, 0. The results are

Table 3. Optimal system of the subalgebra $\{V[2], V[5]\}$.

Dimension	Subalgebras
2	$\{V[2], V[5]\}$
1	$\{V[2] + u_5V[5]\}$, $u_5 \neq 0$, $\{V[2]\}$, $\{V[5]\}$

For the rank 0 the upper left matrix $(2, 5)$ only contains 0. So we have to consider the matrix containing the last two lines of (7). The block matrix with $(3, 6)$ index runs through all subalgebras of Table 2. The final result of this calculation step is

Table 4. Optimal system of the subalgebra $\{V[2], V[5], V[3], V[6]\}$.

Dimension	Subalgebras
4	$\{V[3], V[6], V[2], V[5]\}$
3	$\{V[3], V[6], V[2] + x5V[5]\}, \{V[3], V[6], V[2]\}, \{V[3], V[6], V[5]\}$ $\{V[3] + x6V[6], V[2], V[5]\}, \{V[3], V[2], V[5]\}, \{V[6], V[2], V[5]\}$
2	$\{V[3] + x_6V[6], V[2] + x_5V[5]\}, \{V[3] + x_6V[6], V[2]\}, \{V[3] + x_6V[6], V[5]\},$ $\{V[3], V[2] + x_5V[5]\}, \{V[3], V[2]\}, \{V[3], V[5]\}, \{V[6], V[2] + x_5V[5]\}, \{V[6], V[2]\},$ $\{V[6], V[5]\}, \{V[2], V[5]\}, \{x_2V[2] + x_5V[5] + V[3], y_2V[2] + y_5V[5] + V[6]\},$ $\{x_2V[2] + x_5V[5] + V[3] + x_6V[6], y_2V[2] + y_5V[5]\}, \{x_2V[2] + x_5V[5] + V[3], y_2V[2] + y_5V[5]\},$ $\{x_2V[2] + x_5V[5] + V[6], y_2V[2] + y_5V[5]\}, \{V[3], V[6]\}$
1	$\{V[2] + x_5V[5]\}, \{V[2]\}, \{V[5]\}, \{V[3] + x_6V[6]\}, \{V[3]\}, \{V[6]\}$

In the next step of our algorithm [2], we have to consider the properties of the matrix

$$\begin{pmatrix} a_1 & a_4 & a_7 & a_5 & a_3 & a_6 \\ b_1 & b_4 & b_7 & b_5 & b_3 & b_6 \\ c_1 & c_4 & c_7 & c_5 & c_3 & c_6 \\ u_1 & u_4 & u_7 & u_5 & u_3 & u_6 \\ v_1 & v_4 & v_7 & v_5 & v_3 & v_6 \\ x_1 & x_4 & x_7 & x_5 & x_3 & x_6 \\ y_1 & y_4 & y_7 & y_5 & y_3 & y_6 \end{pmatrix}. \tag{8}$$

It desintegrates into a block structure where we have to consider the matrix in the upper left corner (first three lines) with the indices $(1, 3, 7)$. It allows the ranks 3, 2, 1, 0. The result of this classification is

Table 5. Optimal system of the subalgebra $\{V[1], V[4], V[7]\}$.

Dimension	Subalgebras
3	$\{V[1], V[4], V[7]\}$
2	$\{V[1] + a_7V[7], V[4] + b_7V[7]\}, \{V[1] + a_4V[4], V[7]\}, \{V[4], V[7]\}$
1	$\{V[1] + a_4V[4] + a_7V[7]\}, \{V[1] + a_7V[7]\}, \{V[1]\}, \{V[4] + a_7V[7]\}, \{V[7]\}$

By taking into account the block structure we have the matrix in the upper left corner with the indices $(1, 4, 7)$ (first three lines) and the matrix in the right left corner with the indices $(2, 5, 3, 6)$ (last four lines). To classify the whole matrix (8) every subalgebra of the upper left corner from Table 5 has to combine with every subalgebra of the lower right corner from Table 4.

For the rank 0 we have to investigate the matrix built by the last four lines of (8). The block matrix with the indices $(2, 5, 3, 6)$ runs through all subalgebras of Table 4. The final result of classifying this matrix is given in Table 6.

Table 6. Optimal system of the subalgebra $\{V[1], V[4], V[7], V[2], V[5], V[3], V[6]\}$.

Therefore the subalgebras of L_7 are classified. We can find one 7-dimensional, 9 six-dimensional, 39 five-dimensional, 145 four-dimensional, 168 three-dimensional, 88 two-dimensional, 7 one-dimensional and one zero-dimensional subalgebras.

5 Conclusion

In our examination we have calculated the infinitesimals for each equation of the set of Doebner–Goldin–Madelung models. We found 10-, 8- and 7-dimensional algebras which were investigated. For the 7-dimensional algebra we have determined the optimal systems.

By application of the statements at the beginning of Section 4 we can calculate for every one and two-dimensional optimal-system the related reduction. In the case of the one-dimensional optimal system the result is a system of equations with two new independent variables whether for the 2-dimensional optimal system the reduced system will be an ordinary differential equation system which can be solved. More details can be found in [2]. In this situation we want to emphasize that it is necessary to take isomorphic investigations into account. A closer look at the commutator table shows that the algebras of each dimension look very similar.

We present approaches to systematic description of PDE that display hidden symmetry, with reduced equations having additional symmetry operators compared to the initial equations.

1 Introduction

The concept of conditional symmetry was extensively developed recently following the papers [1] and allowed finding many new solutions of nonlinear differential equations. Here we will consider another facet of the conditional symmetry – additional symmetry of the reduced equations.

"Hidden symmetry" in various contexts is usually a symmetry not obtainable by some standard and straightforward procedure applicable to the models in this context. This term shares the usage of other related terms like "conditional symmetry", "approximate symmetry", and "symmetry" or "invariance" when the same words may denote rather different concepts. Here we will consider hidden symmetry of partial differential equations similarly to Type II hidden symmetry of ordinary differential equations according to [2]. With respect to ODE such symmetry arises as symmetry of equations with reduced order that is not a symmetry of the original equations. In the same way, for a PDE it is symmetry of the reduced equation (with reduced number of independent variables) not present in the original equation.

Definition 1. A differential equation is said to have *hidden symmetry* under an operator X if after the process of reduction of the number of independent variables the resulting reduced equation is invariant under the operator X_1 (being the projection of the operator X in new variables) while the original equation is not invariant under the operator X.

Such symmetry is "classical" in the sense that full hidden symmetry of either ODE or PDE may be found by consecutive reduction of the original equation and investigation of Lie symmetries of the reduced equations, as provided by L. Ovsyannikov's *Submodels* programme [3]. "Symmetry" or "Lie symmetry" is determined in accordance to the procedures that may be found e.g. in [4, 5].

The definition of hidden symmetry can be reformulated in terms of the conditional symmetry according to the book [6]. Here we also will take into account the result proved in the paper [7] that conditional invariance of a differential equation under an involutive family of first-order differential operators Q_a is equivalent to possibility of reduction of this equation by means of the ansatz corresponding to this family of operators. Thus, the additional symmetry under the operator X_1 of the reduced equation (hidden symmetry under the operator X for the original equation) turns out to be a conditional symmetry of the original equation under conditions $Q_a[u] = 0$ ($Q_a[u]$ designates characteristics of the vector field Q_a) with all appropriate differential consequences. Note that X_1 is a Lie symmetry of the reduced equation, and we do not add the condition $X[u] = 0$ to the set of conditions, so such operator will not present a purely Q-conditional symmetry in the sense of [6].

Q-conditional symmetry can also be hidden – that is being a new Q-conditional symmetry of the reduced equation. For examples of such symmetries see [8].

In this paper we give an outlook of description of partial differential equations possessing certain hidden symmetries.

Group classification for classes of differential equations is aimed at identification of equations having wider symmetries than the equations of the class in general. For an overview of the group classification problems and the extensive list of related references see [9]. Usually two types of such problems are considered – finding the equations within a general class that are invariant under specific symmetry group, and description of all symmetries (up to appropriately chosen equivalence) of equations that belong to the specific class. On the basis of the known algorithms for group classification of differential equations in the Lie's sense we develop approaches for a systematic description of classes of nonlinear PDEs that display hidden symmetry.

Definition 2. A class of equations can be regarded as *general* if any local transformations of dependent and independent variables transform an equation from this class into another equation within the same class.

An example is the class of all kth-order PDEs $F = F(x, u, \underset{1}{u}, \dots, \underset{k}{u}) = 0$ with x, u being respectively n- and m-dimensional independent and dependent variables, $\underset{r}{u}$ being the set of all rth-order partial derivatives of the function $u = \big(u^1, u^2, \dots, u^m\big)$. Group classification even with respect to the Lie symmetry for the general classes is usually an overwhelming task, and, to our knowledge, such problem was completely solved only for single ordinary differential equations by S. Lie [10]. A restricted, but practically important problem for the general classes of equations would be description of all equations within the class invariant under some specified symmetry group that can be done by describing all differential invariants for such group. Similarly, description of equations having specified Lie symmetry and specified hidden symmetry may be done by means of conditional differential invariants, as shown in Section 2.

For a more specific class it may be possible to make full group classification of a system consisting of the original equation together with the reduction conditions of the type $Q_a[u] = 0$ (with appropriate prolongations of the conditions), as shown in the Section 3.

2 Description of all equations in a general class possessing particular hidden symmetry

The first example is the general first-order partial differential equation with one dependent and three independent variables of the form

$$F = F(x, y, z, u, u_x, u_y, u_z) = 0. \tag{1}$$

We describe all such equations having Lie symmetry with respect to the operator ∂_x and hidden symmetry with respect to the operator ∂_y after reduction by means of the operator ∂_x. The condition of such Lie and hidden symmetry, according to Definition 1, is invariance of the equation (1) under the operator ∂_y on condition that $u_x = 0$:

$$\partial_x F\big|_{F=0} = 0, \qquad \partial_y F\big|_{F=0,\ u_x=0} = 0. \tag{2}$$

The general solution of the condition (2) will be a function of all invariants of the operators ∂_x and ∂_y, that is z, u, u_x, u_y, u_z, and of the conditional invariant $r = u_x R(y, z, u, u_x, u_y, u_z)$ (being an absolute invariant of ∂_x), where R is an arbitrary function that is reasonably determined on the manifold $u_x = 0$:

$$F(r, z, u, u_x, u_y, u_z) = 0, \tag{3}$$

F has to be a function of the invariants of the hidden symmetry operator on the manifold determined by the reduction condition, and have arbitrary form elsewhere. Note that the function r in (3) is not arbitrary: we cannot take e.g.

$$r = R_1(y, z, u, u_x, u_y, u_z) = u_x \frac{R_1}{u_x}$$

as such $R = \frac{R_1}{u_x}$ will be in the general case undetermined on the manifold $u_x = 0$.

Definition 3 ([12]). A function $F(x, u, \underset{1}{u}, \dots, \underset{k}{u})$ is a *conditional differential invariant* of the operator Q, if under the conditions $G(x, u, \underset{1}{u}, \dots, \underset{r}{u}) = 0$ the relations $Q[F] = 0$, $Q[G] = 0$ are satisfied. We take prolongations of the operators of the order $\max(k, r)$.

A set of invariants of the order $r \le k$ of the operator Q with the conditions $G = 0$ is called a *generating set* of the kth-order conditional differential invariants of Q if all other invariants can be represented as functions of invariants from this set.

Invariants in such generating set may be both absolute invariants of Q and G-conditional of the form $G^{(l)} \times R_{(l)}$, where $G^{(l)}$ are derivatives of G of the order $l \le k - r$ and $R_{(l)}$ are arbitrary functions determined on the manifold $G^{(k)} = 0$ for all values of k.

Number of functionally independent Q-absolute invariants in the generating set of conditional differential invariants can be calculated similarly to the number of invariants in a functional basis of absolute differential invariants, as $m - 1$, where m is the number of variables in the set $x, u, \underset{1}{u}, \dots, \underset{k}{u}$. Number of linearly independent purely G-conditional invariants is equal to the number of independent conditions of the type $G^{(l)} = 0$.

In some cases we would be able to construct a functional basis of conditional invariants, i.e. the maximal set of functionally independent conditional invariants. That is possible in the case when we put a requirement that our conditional invariants should be also absolute invariants of some Lie algebra L, and additional conditions $G = 0$ in the Definition 3 and their relevant differential consequences are not invariant under L.

Equation (3) is reduced by means of the operator ∂_x to the equation $F(0, z, u, 0, u_y, u_z) = 0$ that is invariant with respect to ∂_y. If $R_y \neq 0$ in the expression for r in (3) then this equation is not invariant with respect to the operator ∂_y, so such symmetry is purely hidden.

This example is easily generalised for larger order of equations or number of reduction operators.

The second example is hidden projective symmetry presented by the operator ($m \neq 0$)

$$A = (x_0 - x_2)^2(\partial_0 - \partial_2) + (x_0 - x_2)x_1\partial_1 + \frac{imx_1^2}{2}(u\partial_u - u^*\partial_{u^*}) - (x_0 - x_2)(u\partial_u + u^*\partial_{u^*}) \tag{4}$$

for the d'Alembert equation

$$\Box u = \lambda u|u|^4, \tag{5}$$

here $u = u(x_0, x_1, x_2)$ is a complex-valued function, $|u| = (uu^*)^{1/2}$.

The maximal invariance algebra of the equation (5) is the Poincaré algebra extended by the dilation and charge operators (see e.g. [6] and references therein), with basis operators

$$p_\mu = ig_{\mu\nu}\frac{\partial}{\partial x_\nu}, \quad J_{\mu\nu} = x_\mu p_\nu - x_\nu p_\mu,$$
$$D = x_\mu p_\mu - \frac{i}{4}(u\partial_u + u^*\partial_{u^*}), \quad J = i(u\partial_u - u^*\partial_{u^*}), \tag{6}$$

where μ, ν take the values 0, 1, 2; the summation is implied over the repeated indices (small Greek letters) in the following way: $x_\nu x_\nu \equiv x_\nu x^\nu \equiv x^\nu x_\nu = x_0^2 - x_1^2 - x_2^2$, $g_{\mu\nu} = \operatorname{diag}(1, -1, -1)$.

This equation can be reduced by means of the ansatz ($m \neq 0$)

$$u = \exp\left(\frac{-im(x_0 + x_2)}{2}\right)\Phi(x_0 - x_2, x_1) \tag{7}$$

to the Schrödinger equation

$$2im\Phi_t + \Phi_{xx} = \Phi|\Phi|^4, \qquad t = x_0 - x_2, \qquad x = x_1. \tag{8}$$

The ansatz (7) corresponds to the following additional condition with its conjugate:

$$u_0 + u_2 + imu = 0. \tag{9}$$

Such reduction allowed construction of numerous new solutions for the nonlinear wave equation by means of the solutions of a nonlinear Schrödinger equation [11]. Here reduction gives additional symmetry properties for equation (5), related to the symmetry properties of the equation (8). This equation is invariant, beside the Galilei algebra and the dilation operator

$$\begin{aligned} &\partial_t, \quad \partial_x, \quad J_1 = i(\Phi\partial_\Phi - \Phi^*\partial_{\Phi^*}), \quad G = t\partial_x + xJ_1, \\ &\hat{D}_1 = 2t\partial_t + x\partial_x - I \quad (\text{here } I = i(\Phi\partial_\Phi + \Phi^*\partial_{\Phi^*})) \end{aligned} \tag{10}$$

(see e.g. [6]), under the projective operator equal to the operator A in the new variables t, x, Φ

$$A_1 = t^2\partial_t + tx\partial_x + \frac{im}{2}x^2J_1 - tI. \tag{11}$$

This is one of the immediate examples of hidden symmetry: when presence of some conformal- or projective-type symmetry in a nonlinear equation depends on both the degree of the polynomial nonlinearity and the number of independent variables, such symmetry will exist as hidden in equations with the degree of the polynomial nonlinearity corresponding to the smaller number of independent variables. Note that the operator $\hat{D}_1$ in (10) is not a projection of D in (6), but leads to another hidden symmetry operator $\hat{D} = x_\mu p_\mu - i(u\partial_u + u^*\partial_{u^*})$.

Here we will present full description of Poincaré-invariant equations possessing such hidden symmetry with respect to the operator (4). This is done by means of conditional differential invariants introduced in [12]. Note that in our example we do not require Poincaré invariance of the additional condition itself, so we are able to construct a functional basis of conditional differential invariants.

We adduce functional bases of differential invariants that may be utilised for construction of classes of Poncaré-invariant equations with hidden symmetry (4).

First we present according to [13] a functional basis of absolute differential invariants of the second order for the Poincaré algebra $\langle p_\mu, J_{\mu\nu}\rangle$ (6) and the complex-valued scalar function $u = u(x_0, x_1, x_2)$. It consists of 17 invariants

$$\begin{aligned} &u,\ u^*,\ u_\mu u_\mu,\ u^*_\mu u^*_\mu,\ \Box u,\ \Box u^*,\ u_{\mu\nu}u_{\mu\nu},\ u_{\mu\nu}u^*_{\mu\nu},\ u^*_{\mu\nu}u^*_{\mu\nu},\ u_\mu u_{\mu\nu}u_\nu,\ u^*_\mu u_{\mu\nu}u^*_\nu, \\ &u_\mu u_{\mu\nu}u_{\nu\lambda}u_\lambda,\ \ u^*_\mu u_{\mu\nu}u_{\nu\lambda}u^*_\lambda,\ \ u_{\mu\nu}u_{\nu\lambda}u_{\lambda\mu},\ \ u_{\mu\nu}u_{\nu\lambda}u^*_{\lambda\mu},\ \ u_{\mu\nu}u^*_{\nu\lambda}u^*_{\lambda\mu},\ \ u^*_{\mu\nu}u^*_{\nu\lambda}u^*_{\lambda\mu}. \end{aligned} \tag{12}$$

A functional basis of differential invariants for the Galilei algebra (10), mass $m \neq 0$, of the second order for the complex-valued scalar function $\Phi = \Phi(t, x)$ consists of 10 invariants that can be checked by direct calculation.

For simplification of the expressions for differential invariants we introduced the following notations: $\phi = \ln\Phi$, and to ensure that ϕ is single-valued we choose it so as $\operatorname{Im}\Phi = \arctan\frac{\operatorname{Re}\phi}{\operatorname{Im}\phi}$.

The elements of the functional basis may be chosen as follows:

$$\phi + \phi^*, \quad \phi_x + \phi^*_x, \quad M_1 = 2im\phi_t + \phi^2_x, \quad M^*_1, \quad \phi_{xx}, \quad \phi^*_{xx},$$

$$\theta = im\phi_{tx} + \phi_x\phi_{xx}, \quad \theta^*, \quad M_2 = -m^2\phi_{tt} + 2im\phi_x\phi_{tx} + \phi_x^2\phi_{xx}, \quad M_2^*. \tag{13}$$

A functional basis of differential invariants for the Galilei algebra extended by the dilation operator (10) and the projective operator (11) may be chosen as follows:

$$N_1e^{-4(\phi+\phi^*)}, \quad \frac{N_1}{N_1^*}, \quad \frac{N_2}{N_1^2}, \quad \frac{N_2^*}{(N_1^*)^2}, \quad \frac{\phi_{xx}+\phi_{xx}^*}{N_1}, \quad \frac{\theta}{N_1^{\frac{3}{2}}}, \quad \frac{\theta^*}{N_1^{\frac{3}{2}}}, \quad \frac{(\phi_x+\phi_x^*)^2}{N_1},$$

where

$$N_1 = M_1 + \phi_{xx} = 2im\phi_t + \phi_{xx} + \phi_x^2, \qquad N_2 = \phi_{xx}N_1 + \frac{\phi_{xx}^2}{2} + M_2. \tag{14}$$

An algorithm for construction of conditional differential invariants may be derived directly from the Definition 3. We can construct differential invariants of the Poincaré algebra $\langle p_\mu, J_{\mu\nu}\rangle$ (6) being conditional differential invariants of the projective operator (4) solving the system

$$\underset{2}{A}_1F(\mathrm{Inv}_P) = 0, \qquad u_0 + u_2 + imu = 0, \qquad \frac{\partial}{\partial x_\mu}(u_0 + u_2 + imu) = 0, \quad \mu = 0,1,2,$$

where Inv_P are all differential invariants (12) of the Poincaré algebra $\langle p_\mu, J_{\mu\nu}\rangle$ (6). Using the fact that the ansatz (7) is the general solution of the additional condition (9), we can directly substitute this ansatz into differential invariants (12). The expression $\Box u$ transforms into uN_1, where N_1 is an expression entering into expression for differential invariants (14). Substituting the ansatz (7) into all elements of the fundamental basis (12) of second-order differential invariants of the Poincaré algebra, we can obtain a reduced basis of differential invariants that may be used for construction of all equations reducible by means of this ansatz to equations possessing the projective symmetry. We can give the following representation of the Poincaré invariants using expressions M_k (13) and N_k (14):

$$u_\mu u_\mu = u^2M_1, \ u_\mu u_\mu^* = \frac{uu^*}{2}\big(M_1 + M_1^* - (\phi_x+\phi_x^*)^2\big), \ u_{\mu\nu}u_{\mu\nu} = u^2\big(2M_2 + M_1^2 + \phi_{xx}^2\big),$$
$$u_{\mu\nu}u_{\mu\nu}^* = uu^*\Big(M_2 + M_2^* + \frac{1}{4}\big(M_1 + M_1^* - (\phi_x+\phi_x^*)^2\big)^2 - 2(\theta+\theta^*)(\phi_x+\phi_x^*)$$
$$+ \big(\phi_{xx}+\phi_{xx}^*\big)(\phi_x+\phi_x^*)^2 + \phi_{xx}\phi_{xx}^*\Big), \quad u_\mu u_\nu u_{\mu\nu} = u^3\big(M_2 + M_1^2\big),$$
$$u_\mu^* u_\nu^* u_{\mu\nu} = uu^{*2}\Big(M_2 - 2\theta(\phi_x+\phi_x^*) + \phi_{xx}(\phi_x+\phi_x^*)^2 + \frac{1}{4}\big(M_1 + M_1^* - (\phi_x+\phi_x^*)^2\big)^2\Big),$$

with similar, however more cumbersome expressions for other invariants. Note that it is convenient to use for expression of the projective conditional invariants not only invariants from the fundamental basis (12) but also other invariants (that are anyway functions of (12)).

We construct Poincaré-invariant conditional differential invariants of the projective operator (4) under the condition (9) using differential invariants (13)

$$I_1 = N_1e^{-4(\phi+\phi^*)} = \frac{\Box u}{u(uu^*)^2}, \quad I_2 = \frac{N_1}{N_1^*} = \frac{u^*\Box u}{u\Box u^*},$$
$$I_3 = \frac{N_2}{N_1^2} = \left(uu_\mu u_\nu u_{\mu\nu} + \frac{3}{2}u^2(\Box u)^2 + \frac{1}{2}(u_\mu u_\mu)^2 - 2u\Box u(u_\mu u_\mu)\right)\big(u^2(\Box u)^2\big)^{-1}, \quad I_3^*,$$
$$I_4 = \frac{(\phi_x+\phi_x^*)^2}{N_1} = \frac{u_\mu u_\mu u^{*2} + u_\mu^* u_\mu^* u^2 - 2u_\mu u_\mu^* uu^*}{uu^{*2}\Box u},$$
$$I_5 = \frac{(\phi_{xx}+\phi_{xx}^*)}{N_1} = \frac{u^*\Box u + u\Box u^* - 2u_\mu u_\mu^*}{u^*\Box u}, \quad I_6 = \frac{\theta}{2N_1} = \big(- u^3u_\mu^*u_\nu^*u_{\mu\nu}$$

$$+ u^{*2}\big(uu_\mu u_\nu u_{\mu\nu} - (u_\mu u_\mu)^2\big) + (u\Box u - u_\mu u_\mu)\big(u_\mu u_\mu u^{*2} + u^*_\mu u^*_\mu u^2 - 2u_\mu u^*_\mu u u^*\big)$$
$$+ (uu_\mu u^*_\mu)^2\big)\big(u^2 u^* \Box u (u_\mu u_\mu u^{*2} + u^*_\mu u^*_\mu u^2 - 2u_\mu u^*_\mu u u^*)^{1/2}\big)^{-1}, \quad I^*_6. \tag{15}$$

The expressions (15) form a functional basis of invariants that are absolute differential invariants for the operators of the extended Poincaré algebra (6) and conditional invariants of the operator A (4) with the additional condition (9). Functional independence of the expressions (15) can be checked directly, most easily by application of the additional conditions, that is by substitution of the ansatz (7) into (15), with the "reduced basis" obtained as a result. The reduced invariants in the basis will depend on new functions without conditions and will be absolute invariants of the operators $\langle G, J, \hat{D}_1, A_1\rangle$.

Calculation of the number of invariants in such basis may be also considered as follows:

$$\begin{aligned}\text{Number of invariants} = {}& \text{Number of (variables + derivatives)}\\ & - \big(\text{Rank of the set of operators}\\ & + \text{Number of independent conditions and their derivatives}\big).\end{aligned}$$

We have 20 dependent variables and derivatives, 8 conditions ((9) with the conjugate and derivatives), and the rank of the set of operators $\langle J_{\mu\nu}, \hat{D}, J, A\rangle$ under the conditions (9) with the conjugate and derivatives is equal to 6 with all conditions taken into account.

However, the number of conditional differential invariants in the considered example is 8 and not $6 = 20 - 8 - 6$ as it may seem to be. However, if we apply the additional condition (9) and its first derivatives with respective conjugates (8 conditions) to the fundamental basis of invariants of the Poincaré algebra (12) (17 invariants), we will obtain 11 independent reduced invariants, as may be checked by direct calculation. So two of the conditions appear to be dependent on the manifold of invariants, and with other 3 conditions of invariance with respect to operators $\langle \hat{D}, J, A\rangle$ we obtain 8 invariants in the functional basis of conditional differential operators. Thus, we arrived to the following statement.

Proposition 1. *All equations of the form*

$$F(I_1, I_2, I_3, I^*_3, I_4, I_5, I_6, I^*_6) = 0 \tag{16}$$

are conditionally invariant with respect to the operator A (4) *with the additional condition* (9). *All equations that are invariant with respect to the algebra* (6) *and conditionally invariant with respect to the operator* A (4) *with the additional condition* (9) *have the form* (16).

Note that in this example we required the equations to be invariant in the Lie sense under the algebra (6), and the condition (9) is not invariant with respect to this algebra. So we do not have conditional invariants with arbitrary functions of the type $(u_0 + u_2 + imu) \times$ (arbitrary function). In general, if we require some hidden or conditional invariance producing conditional invariants with arbitrary functions together with some Lie invariance, we may require Lie invariance of an equation depending on such conditional invariants. Moreover, the operators $\langle J_{\mu\nu}, \hat{D}, J, A\rangle$ do not form an algebra, and we would not be able to use absolute differential invariants in the Lie sense to describe invariant equations similarly to the example of the equation (1) and its reduction under the operator ∂_y.

3 Finding hidden symmetries

"Simple" hidden symmetries (Lie symmetries of reduced equations) for a particular class of equations can be found by means of consecutive Lie reductions and consecutive finding Lie symmetries of the reduced equations. Group classification of such class with respect to hidden

symmetries of reduced equations will involve description of all possible reductions and group classification of the respective classes of reduced equations. Here we will consider a rather simple example of the nonlinear wave equation in two spatial dimensions

$$\Box u = f(x_0, x_1, x_2, u) \tag{17}$$

that will allow us to illustrate the proposed algorithm. We present group classification of this equation with respect to hidden symmetries for reduction by means of the operator ∂_{x_2}.

Such reduction leads to the two-dimensional wave equation $u_{00} - u_{11} = f(x_0, x_1, u)$. The next step is the usual group classification of the reduced equation. It will be more convenient to use the substitution $\tau = x_0 + x_1$, $\omega = x_0 - x_1$ and to go to the equation

$$u_{\tau\omega} = F(\tau, \omega, u). \tag{18}$$

The equivalence group of equation (18) (see [14]) consists of the continuous transformations (for the definitions and calculation procedures of equivalence transformation groups see [4, 15])

$$\tau' = T(\tau), \quad \omega' = W(\omega), \quad u' = e^{\lambda}u + U(\tau, \omega), \quad F' = \frac{1}{\dot{T}(\tau)\dot{W}(\omega)}(e^{\lambda}F + U_{\tau\omega}), \tag{19}$$

where T, W, U are arbitrary (T, W do not take constant values simultaneously) functions of their arguments and dots over the letters mean derivatives, and discrete transformations $\tau' = \epsilon\epsilon_1\omega + (1-\epsilon)\epsilon_2\tau$, $\omega' = \epsilon\epsilon_3\tau + (1-\epsilon)\epsilon_4\omega$, $u' = \epsilon_5 u$, $F' = \epsilon_5(\epsilon\epsilon_1\epsilon_3 + (1-\epsilon)\epsilon_2\epsilon_4)\, F(\tau', \omega', u')$ ($\epsilon = 0, 1$, $\epsilon_k = \pm 1$, $k = 1, 2, \ldots, 5$), together with products of continuous and discrete transformations.

Group classification of the equation (18) is given in [4] ($F_{uu} = 0$) and in [14] ($F_{uu} \neq 0$). Such group classification was performed up to transformations from the equivalence group of the equation. However, if we multiply the resulting inequivalent invariant equations by means of transformations from the equivalence group (19) that do not belong to the equivalence group of equation (17) and then add u_{22} ("reverse reduction"), we will obtain description of equations with hidden symmetry.

For example, when $F = F(\rho_1(\tau) - \rho_2(\omega), u)$, equation (18) is invariant with respect to the operator $Q = \rho_1'\partial_\tau + \rho_2'\partial_\omega$ (primes here designate derivatives). So, the equations from the class (17) $\Box u = f(\rho_1(\tau) - \rho_2(\omega), x_2, u)$ will have hidden invariance with respect to the operator Q with appropriate change of variables in Q. It quite obvious that such transformed Q is not a Lie symmetry operator for the above equation except if $\rho_1 = a\tau + b$, $\rho_2 = a\omega + c$, a, b, c are constants.

Similarly, for $f = \exp(\rho_1(\tau) + \rho_2(\omega))\, \phi(u \exp(-\rho_1(\tau) - \rho_2(\omega)), x_2)$, there is hidden invariance of (17) with respect to the operators $Q_1 = \rho_1'\partial_\tau + u\partial_u$, $Q_2 = \rho_2'\partial_\omega + u\partial_u$. Here ρ_1, ρ_2 are arbitrary but fixed functions.

We present an algorithm for group classification with respect to hidden symmetry:

Step 1. Obtain reduced equations of for the class of initial PDE.

Step 2. Perform group classification of the reduced equations.

Step 3. Multiply inequivalent invariant reduced equations by means of transformations from the equivalence group of this class.

Step 4. Reverse of the equation: find equations from the initial class of PDE corresponding to the multiplied reduced equations.

Step 5. Find all inequivalent equations with respect to transformations from the equivalence group of the initial class of PDE.

4 Discussion

We see that a nontrivial hidden symmetry for partial differential equations stems from the reduced equations having wider equivalence group than the original equations. So group classification of the classes of equations with respect to hidden symmetry involves study of equivalence

groups of such classes, in the similar way as it is done for classification with respect to the Lie symmetry. Description of hidden symmetry of physically interesting classes of equations would allow to identify wider classes of reducible equations than it is possible by means of group classification in the Lie sense. The special interest in such classification lies in that reduced equations often have infinite-dimensional equivalence groups that allows to obtain classes of equations with hidden symmetry that have large degree of arbitrariness.

Reduction of some wave and heat equations by means of ansatzes in special coordinate systems results in PDEs with additional symmetry operators compared to original ones. Such operators will allow constructing sets of conditional symmetry operators that represent hidden symmetry of the equations. Classes of generalised wave and heat equations possessing these symmetry properties are described, and families of respective nonclassical solutions are listed.

1 Example 1: Linear wave equation

Let us consider the linear wave equation

$$\Box u = ku \tag{1}$$

for the real-valued function $u = u(x_0, x_1, x_2, x_3)$, $x_0 = t$ is the time variable, x_1, x_2, x_3 are space variables. $\Box$ is the d'Alembert operator

$$\Box u = -\frac{\partial^2 u}{\partial x_0^2} + \frac{\partial^2 u}{\partial x_1^2} + \frac{\partial^2 u}{\partial x_2^2} + \frac{\partial^2 u}{\partial x_3^2}.$$

The maximal invariance algebra (without trivial operators $u\partial_u$, $f(x)\partial_u$ ($\Box f = 0$) taken into account) of the equation (1), $k \neq 0$, is the Poincaré algebra $AP(1,3)$ with the basis operators

$$p_\mu = ig_{\mu\nu}\frac{\partial}{\partial x_\nu}, \qquad J_{\mu\nu} = x_\mu p_\nu - x_\nu p_\mu,$$

where μ, ν take the values 0, 1, 2, 3; $g_{\mu\nu} = \operatorname{diag}(1, -1, -1, -1)$.

Similarity solutions for the equation (1) can be found by means of symmetry reduction by non-equivalent subalgebras of the algebra $AP(1,3)$ [1–4]. In such a way it is possible to obtain solutions in the form $u = \phi(\omega)$, where ω is an invariant of some subalgebra of the Poincaré algebra $AP(1,3)$.

Here we will look for solutions of the equation (1) in the form $u = f(x)\phi(\omega)$, with f and ω being some functions on x. Ansatzes of such form are usually obtained in the process of reduction of wave equations having scale invariance under subalgebras containing scale transformations $D = x^\nu p_\nu + \lambda i u\partial_u$. However, we can obtain a solution with such ansatzes for the equation (1) that is not invariant scale transformations.

We can reduce the equation (1) by means of the ansatz

$$u = f(r)\phi(\omega), \qquad r = \left(x_1^2 + x_2^2 + x_3^2\right)^{1/2}, \qquad \omega = r + vx_0.$$

The general form of the reduced equation will be

$$\left(v^2 - 1\right) f\phi'' - 2\left(f' + \frac{1}{r}f\right)\phi' - \left(f'' + \frac{2}{r}f' + kf\right)\phi = 0, \tag{2}$$

and the reduction conditions (when $f \neq 0$ and $\phi \neq 0$) are as follows: when v is an arbitrary parameter, $v^2 - 1 \neq 0$, then

$$f' + \frac{1}{r} f = \lambda f, \qquad f'' + \frac{2}{r} f' = \gamma f,$$

with λ, γ being arbitrary constants. This system is compatible if and only if $\gamma = \lambda^2$, and the ansatz takes the form

$$u = \frac{c \exp \lambda r}{r} \phi(\omega), \tag{3}$$

where $\omega = r + vx_0$; c, λ, $v \neq \pm 1$, $v \neq 0$ are arbitrary constants. The reduced equation has the form $\left(v^2 - 1\right) \phi'' - 2\lambda\phi' - \left(\lambda^2 + k\right) \phi = 0$.

When $v = \pm 1$, there may be several types of the reduction conditions.

1. With

$$f' + \frac{1}{r} f \neq 0, \qquad f'' + \frac{2}{r} f' + kf \neq 0, \qquad \alpha \neq 0,$$

the reduction condition will have the form

$$\alpha \left(f' + \frac{1}{r} f \right) = f'' + \frac{2}{r} f' + kf,$$

and the corresponding ansatzes are

$$u = \frac{1}{r} \exp \frac{\alpha r}{2} [c_1 \cosh \beta r + c_2 \sinh \beta r] \phi(\omega), \qquad 0 > k - \frac{\alpha^2}{4} = -\beta^2; \tag{4}$$

$$u = \frac{1}{r} \exp \frac{\alpha r}{2} [c_1 \cos \beta r + c_2 \sin \beta r] \phi(\omega), \qquad 0 < k - \frac{\alpha^2}{4} = \beta^2; \tag{5}$$

$$u = \frac{1}{r} \exp \frac{\alpha r}{2} [c_1 r + c_2] \phi(\omega), \qquad 0 = k - \frac{\alpha^2}{4}; \tag{6}$$

the reduced equation for ϕ will be $\phi' + \alpha\phi = 0$ and its solution $\phi = c \exp\left(-\frac{\alpha\omega}{2}\right)$ gives exact solutions for the equation (1).

2. With

$$f' + \frac{1}{r} f = 0, \qquad f'' + \frac{2}{r} f' + kf = 0,$$

ϕ may be an arbitrary function. It is evident that $f = 0$ if $k \neq 0$. If $k = 0$, $f = \frac{c}{r}$, and we obtain the well-known Euler solution for the wave equation $\Box u = 0$:

$$u = \frac{c}{r} \phi(r \pm t),$$

where ϕ is an arbitrary function. This solution is obtained from the degenerate case of the reduced equation (2) with all coefficients at and functions vanishing, so the solution of the resulting reduced equation is an arbitrary function. This solution corresponds to the hidden symmetry of the wave equation, represented by Lie infinite-dimensional symmetry algebra of the reduced equation $\phi_{tt} - \phi_{rr} = 0$, $u = \frac{c}{r} \phi(r, t)$.

3. With

$$f' + \frac{1}{r} f \neq 0, \qquad f'' + \frac{2}{r} f' + kf = 0,$$

$\phi' = 0$, $\phi = \text{const}$. The resulting solutions have the form $u = u(r)$ and are similarity solutions that may be obtained from the Lie symmetry of the equation (1).

It is quite obvious that ansatzes of the form (3)–(6) cannot be obtained by reduction of the equation (1) by subalgebras of the Poincaré algebra $AP(1,3)$

The ansatz (3) corresponds to the set of operators Q_1, J_{ab}, where $a,b=1,2,3$ and Q_1 has the form

$$Q_1 = x_a\partial_a - \frac{r}{v}\partial_0 + (\lambda r - 1)u\partial_u. \tag{7}$$

This set of operators determines conditional invariance of the equation (1), and the ansatz (3) allows to obtain new solutions compared to those that may be obtained by means of Lie symmetry operators. Note that these operators do not form an algebra.

We present other such operators $Q_{(1,i)}$ determining conditional invariance of the equation (1):

$$Q_{(1,1)} = x_a\partial_a + r\partial_0 + k^{1/2}ru\partial_u;$$
$$Q_{(1,2)} = x_a\partial_a + r\partial_0 + \left(\frac{\alpha}{2} - \frac{1}{r} + \left(k - \frac{\alpha^2}{4}\right)^{1/2}\operatorname{tg} r\right)u\partial_u;$$
$$Q_{(1,3)} = x_a\partial_a + r\partial_0 + \left(\frac{\alpha}{2} - \frac{1}{r} + \left(k - \frac{\alpha^2}{4}\right)^{1/2}\operatorname{ctg} r\right)u\partial_u.$$

These operators generate scale-type transformations of the space variables.

We adduce here some of the families of exact solutions for the equation (1):

$$u = \frac{c\exp\lambda r}{r}[c_1\exp(\lambda+\alpha)l\omega + c_2\exp(\lambda-\alpha)l\omega], \qquad 0 < v^2(k+\lambda^2) - k = \alpha^2;$$
$$u = \frac{c\exp(\lambda r+\lambda l\omega)}{r}[c_1\cos l\alpha\omega + c_2\sin l\alpha\omega], \qquad 0 > v^2(k+\lambda^2) - k = -\alpha^2;$$
$$u = \frac{c\exp(\lambda r+\lambda l\omega)}{r}[c_1\omega + c_2], \qquad v^2(k+\lambda^2) - k = 0,$$

$l = 1/(v^2-1)$; c_1, c_2 are arbitrary constants.

2 Example 2: Generalised heat equation

We consider a nonlinear generalised heat equation in the form

$$u_0 + u_{11} + u_{22} + u_{33} = F(x_0, x_1, x_2, x_3, u), \tag{8}$$

where $u_\mu = \frac{\partial u}{\partial x_\mu}$, $u_{\mu\mu} = \frac{\partial^2 u}{\partial x_\mu^2}$; $\mu = 0,1,2,3$.

Classical Lie symmetries with two and three spatial variables with F not depending on x_μ were described in [5].

We consider reductions of the equation (8) to an ODE by means of an ansatz of the form

$$u = \frac{c}{r}\phi(\omega), \qquad r = \left(x_1^2 + x_2^2 + x_3^2\right)^{1/2}, \qquad \omega = r + vx_0, \tag{9}$$

where v is an arbitrary parameter, when $F = \frac{1}{r}\Phi(\omega, ur)$. The reduced equation will then have the form $\phi'' + v\phi' = \Phi(\omega,\phi)$.

The maximal invariance algebra of the equation (8) for the general form of $F = \frac{1}{r}\Phi(\omega, ur)$ is the three-dimensional algebra of rotation operators with a basis J_{ab}, $a,b=1,2,3$, and the ansatz (9) corresponds to the set of operators $\{Q_2, J_{ab}\}$, where $a,b=1,2,3$ and Q_2 has the form

$$Q_2 = x_a\partial_a - \frac{r}{v}\partial_0 + u\partial_u. \tag{10}$$

This set of operators determines conditional invariance of the equation (8), and the ansatz (9) allows to obtain new solutions compared to those that may be obtained by means of Lie symmetry operators. We will discuss the reduced equation for (8) by means of the ansatz (9) with $F = \lambda r^{k-1} u^k$ that has the form

$$\phi'' + v\phi' = \lambda\phi^k.$$

This equation may be transformed to the second-type Abel equation

$$p'p + vp = \lambda y^k \tag{11}$$

with substitution $\phi' = p$, $\phi = y$, $p = p(y)$.

1. If $k = \frac{1}{2}$ then the equation (11) by means of the transformation $\frac{s'}{s} = y^{1/2}$, $-\frac{1}{v}p = -\frac{z}{2A}$, $A = \frac{\lambda}{v^2}$ reduces to the Bessel equation

$$s'' - \frac{z}{2A}s = 0.$$

2. If $k = -1$ then the equation (11) is the Liouville equation $p'p + vp = \lambda y^{-1}$. By means of the substitution $-\frac{1}{v}p = y + z$, $y = \frac{1}{u}$ it is reduced to a linear one with respect to the function $u = u(z)$

$$\frac{\lambda}{v^2}u_z + zu + 1 = 0.$$

3. If $k = -2$ then the equation (11) by means of the substitution $-\frac{1}{v}p = y + z$, $\frac{1}{y} = u - \frac{z^2}{2}$ may be transformed to the Riccati equation for the function $z = z(u)$

$$\frac{\lambda}{v^2}z_u + u - \frac{z^2}{2} = 0,$$

whose solution may be expressed via the Bessel function.

3 Definitions and discussion

The concept of non-classical, or conditional symmetry, originated in its various facets in the papers [6–11], and later it was developed by numerous authors into the theory and a number of algorithms for studying symmetry properties of equations of mathematical physics and for construction of their exact solutions (see e.g. [12]). Here we will use the following definition of the conditional symmetry:

Definition 1. The equation $\Phi(x, u, \underset{1}{u}, \ldots, \underset{l}{u}) = 0$, where $\underset{k}{u}$ is the set of all kth-order partial derivatives of the function $u = (u^1, u^2, \ldots, u^m)$, is called conditionally invariant [3] under the operator

$$Q = \xi^i(x, u)\partial_{x_i} + \eta^r(x, u)\partial_{u^r}$$

if there is an additional condition

$$G(x, u, \underset{1}{u}, \ldots, \underset{l_1}{u}) = 0, \tag{12}$$

such that the system of two equations $\Phi = 0$, $G = O$ is invariant (according to the Lie definition, see e.g. [13]) under the operator Q.

If (12) has the form $G = Q[u]$, $Q[u]$ designates $Q[u] = \eta^r(x,u) - \xi^i(x,u)u_{x_i}$, then the equation $\Phi = 0$ is called Q-conditionally invariant under the operator Q [3]. These definitions of the conditional invariance of some equation are based on what is in reality Lie symmetry (see e.g. the classical texts [13–15]) of the same equation with a certain additional condition.

In this paper we develop results previously obtained by the authors in [16–18]. Our examples may be used to illustrate a generalisation of this definition to conditional invariance with a set of conditions $G_m = 0$. We may speak about $\langle Q_m \rangle$-conditional invariance where additional conditions have the form

$$G_m(x, u, \underset{1}{u}, \ldots, \underset{l_1}{u}) = Q_m[u] = 0.$$

However, we see that these examples contain features of two different types of non-classical invariance – hidden symmetry (see [30]) and Q-conditional symmetry.

Definition 2. An equation is said to have hidden conditional invariance if a reduced equation is conditionally invariant under some additional condition.

The equation (1) possesses hidden Q-conditional symmetry with respect to the operators Q_1, $Q_{1,i}$, and the equation (8) possesses hidden Q-conditional symmetry with respect to the operator Q_2, under conditions $J_{ab}u = 0$, $a, b = 1, 2, 3$.

The conditional symmetry of the Klein–Gordon equation was studied in [19, 20]. The conditional symmetry of the nonlinear heat equations with one space variable was extensively studied by numerous authors [6, 21–27, 29]. In [28] all conditional symmetries for an n-dimensional homogeneous linear heat equation were described.

The operators of the hidden conditional symmetry presented in this paper do not belong to sets of operators described in the above-mentioned papers, and they are not obtainable from conditional symmetry of equations with one space dimension. However, the operators we found are linked to the conditional symmetry of the respective radial wave and heat equations

$$u_{tt} - u_{rr} - \frac{n-1}{r}u_r = F_1(u),$$
$$u_t + u_{rr} + \frac{n-1}{r}u_r = F_2(u)$$

(n is the number of spatial variables, here $n = 3$) that present considerable interest by themselves. See e.g. [31, 32], where exact solutions for a n-dimensional radial wave equation with a general power nonlinearity are derived and studied, and [33] for discussion of the linear radial heat equation.

Symmetries of Radial Maxwell–Vlasov Equations

Zygmunt Jacek ZAWISTOWSKI

Institute of Fundamental Technological Research, Polish Academy of Sciences,
Swietokrzyska 21, 00-049 Warsaw, Poland
E-mail: *zzawist@ippt.gov.pl*

Lie group of point symmetries is determined for Vlasov–Maxwell equations of spherically symmetric plasmas. The case of multi-component plasma is considered. Classification of possible invariant solutions is presented. Comparison with the case of one-dimensional rectilinear motion of plasma particles is made.

1 Introduction

The case of purely radial motion of charges is singled out by the general properties of Maxwell equations. Similarly as in one-dimensional rectilinear motion of particles of plasma there is no generation of time dependent magnetic field in this case [1]. Thus, there is no radiation and the self-consistent solutions of the Vlasov–Maxwell equations (distribution functions, electric field and no magnetic field) exist.

The case of one-dimensional rectilinear motion is widely employed in plasma physics [2–5]. It is used as a starting point for analysis of more complicated systems with very significant applications. The same is expected in the case of radial motion, however, this case is not popular and not widely employed. Thus, research into that topic is important and promising.

In this paper we find Lie symmetry groups of point transformations of the Vlasov–Maxwell equations for collision-less multi-component plasma without magnetic field in the case of purely radial motion of particles. We find the optimal system of one-parameter subgroups and classify corresponding invariant solutions.

We use the direct method for determining symmetry groups of integro-differential equations (IDE's) presented in papers [6–8]. For the IDE's of the type

$$F(x_1,\dots,x_n,y,\underset{1}{y},\dots,\underset{m}{y})+\int_X dx_1\cdots dx_l f(x_1,\dots,x_n,y,\underset{1}{y},\dots,\underset{k}{y})=0, \tag{1}$$

where the symbol $\underset{m}{y}$ denotes the set of all partial derivatives of m-order, it consists in the following infinitesimal criterion of invariance

$$G^{(m)}F+\int_X dx_1\cdots dx_l\left[G^{(k)}f+f\sum_{i=1}^{l}\partial_i\xi_i\right]=0 \qquad \text{on solutions of (1)}, \tag{2}$$

where $G^{(m)}$ is the extended to m-th order generator of the point transformation

$$\begin{aligned}&\widetilde{x}^i=e^{\epsilon G}x^i=x^i+\epsilon\xi^i(x,y)+\mathcal{O}\big(\epsilon^2\big),\\ &\widetilde{y}=e^{\epsilon G}y=y+\epsilon\eta(x,y)+\mathcal{O}\big(\epsilon^2\big),\end{aligned} \tag{3}$$

with the generator

$$G=\xi^i(x,y)\partial_{x^i}+\eta(x,y)\partial_y. \tag{4}$$

The method is a natural generalization of the well known Ovsiannikov's method for partial differential equations which can be found in monographs [9–12]. The short review with relevant references of other methods of finding symmetries of integro-differential equations is given in [8].

2 Symmetries of radial multi-component plasma

In the case of purely radial motion the Vlasov–Maxwell system of equations for collision-less, multi-component, plasmas without magnetic field has the following form

$$\begin{aligned}
&\partial_t f_\alpha + u\partial_r f_\alpha + \frac{q_\alpha}{m_\alpha} E \partial_u f_\alpha = 0,\\
&\partial_t E + \sum_\alpha \frac{q_\alpha}{\epsilon_0}\int_0^\infty du\, u^3 f_\alpha = 0, \qquad \partial_r E + \frac{2}{r}\,E - \sum_\alpha \frac{q_\alpha}{\epsilon_0}\int_0^\infty du\, u^2 f_\alpha = 0,
\end{aligned} \tag{5}$$

where $E = E(t,r)$ is the radial component of electric field vector, u is the radial component of vector velocity, $f_\alpha = f_\alpha(t,r,u)$ is the radial distribution function of α-plasma component (integrated over the solid angle in velocity space with 4π included), q_α, m_α are charge and mass of α-particles respectively, and ϵ_0 is electric permittivity of free space.

In this case, the generators (4) of point transformations (3) take the form

$$G = \tau\partial_t + \xi\partial_r + \rho\partial_u + \sum_\alpha \eta_\alpha \partial_{f_\alpha} + \zeta\partial_E. \tag{6}$$

Using the criterion (2) we obtain

$$0 = \partial_{f_\alpha}\tau = \partial_{f_\alpha}\xi = \partial_{f_\alpha}\rho = \partial_E\tau = \partial_E\xi = \partial_E\rho,$$

and the following determining equations (limits 0 and ∞ of integrals are dropped):

$$\begin{aligned}
&0 = \partial_E\eta_\alpha \qquad 0 = \partial_{f_\alpha}\zeta, \qquad 0 = u\partial_u\tau - \partial_u\xi, \qquad 0 = \left(\frac{q_\alpha}{m_\alpha} - \frac{q_\beta}{m_\beta}\right)\partial_{f_\beta}\eta_\alpha \quad \text{for } \alpha \neq \beta,\\
&0 = \partial_t\eta_\alpha + u\partial_r\eta_\alpha + \frac{q_\alpha}{m_\alpha}\,E\partial_u\eta_\alpha, \qquad 0 = u\partial_t\tau - \partial_t\xi + \rho + u^2\partial_r\tau - u\partial_r\xi,\\
&0 = \partial_t\zeta + \frac{2}{r}\,E\partial_t\xi, \qquad 0 = \partial_r\zeta - \frac{2}{r^2}\,E\xi + \frac{2}{r}\,\zeta - \frac{2}{r}\,E\partial_E\zeta + \frac{2}{r}\,E\partial_r\xi,\\
&0 = \frac{q_\alpha}{m_\alpha}E\left(\partial_t\tau + u\partial_r\tau + \frac{q_\alpha}{m_\alpha}E\partial_u\tau - \partial_u\rho\right) + \frac{q_\alpha}{m_\alpha}\,\zeta - \partial_t\rho - u\partial_r\rho,\\
&0 = (\partial_t\tau - \partial_E\zeta)\sum_\beta \frac{q_\beta}{\epsilon_0}\int du\, u^3 f_\beta - (\partial_t\xi)\sum_\beta \frac{q_\beta}{\epsilon_0}\int du\, u^2 f_\beta\\
&\qquad + \sum_\beta \frac{q_\beta}{\epsilon_0}\int du(3u^2\rho f_\beta + u^3\eta_\beta + u^3 f_\beta\partial_u\rho),\\
&0 = (\partial_E\zeta - \partial_x\xi)\sum_\beta \frac{q_\beta}{\epsilon_0}\int du\, u^2 f_\beta + (\partial_r\tau)\sum_\beta \frac{q_\beta}{\epsilon_0}\int du\, u^3 f_\beta\\
&\qquad - \sum_\beta \frac{q_\beta}{\epsilon_0}\int du\big(2u\rho f_\beta + u^2\eta_\beta + u^2 f_\beta\partial_u\rho\big).
\end{aligned}$$

For different species $\alpha \neq \beta$ also $q_\alpha/m_\alpha \neq q_\beta/m_\beta$ for real plasmas (except the special case of deuterium and helium nuclei). This leads to a symmetry group which is completely different from the case of one-component plasma when there is only one value of q/m. This is the reason for the oscillatory like generators for one-component plasma in the case of rectilinear motion of particles to appear, as found by V. Taranov [14]. We easily find that

$$0 = \partial_u\tau = \partial_u\xi = \partial_t\eta_\alpha = \partial_r\eta_\alpha = \partial_u\eta_\alpha = \partial_E\eta_\alpha, \qquad 0 = \partial_{f_\beta}\eta_\alpha \quad \text{for } \alpha \neq \beta, \qquad \zeta = \lambda_1 E.$$

Then, the last two integro-differential equations lead to

$$0 = \int du \left[f_\alpha (u^3 \partial_u \tau - \lambda_1 u^3 - u^2 \partial_t \xi + 3u^2 \rho + u^3 \partial_u \rho) + u^3 \eta_\alpha \right],$$
$$0 = \int du \left[f_\alpha (\lambda_1 u^2 - u^2 \partial_r \xi + u^3 \partial_r \tau - 2u\rho - u^2 \partial_u \rho) + u^2 \eta_\alpha \right].$$

We assume that the point transformations (3) are analytic functions of the point $(t, r, u, f_\alpha, \zeta)$. In general, analyticity with respect to the parameter ϵ and infinite differentiability with respect to the point is assumed for Lie groups. However, the latter dependence is in fact also analytic due to a physical interpretation. Expanding $\eta_\alpha(f_\alpha)$ in the Taylor series, using the generalized mean value theorem and well known special stationary solutions of the Vlasov–Maxwell equations (5), which depend only on velocity, we find that the coefficients η_α can depend on f_α only linearly $\eta_\alpha = \lambda_2 f_\alpha$. Thus, we can apply the Lagrange lemma of calculus of variations [13] and obtain *differential* equations for integrands.

Solutions of the determining equations lead to the following three generators

$$G_1 = \partial_t, \qquad G_2 = -t\partial_t - 2r\partial_r - u\partial_u + 5\sum_\alpha f_\alpha \partial_{f_\alpha},$$
$$G_3 = -3t\partial_t - r\partial_r + 2u\partial_u + 5E\partial_E, \tag{7}$$

which span the Lie algebra of the group of point symmetry transformations of the Vlasov–Maxwell equations (5). Non-vanishing commutators between these generators are given by

$$[G_1, G_2] = -G_1, \qquad [G_1, G_3] = -3G_1, \qquad [G_2, G_3] = 0.$$

The algebra is solvable.

Summing up the Lie series we obtain one-parameter subgroups of the symmetry group of transformations corresponding to the generators (7). For G_1 we have translations in time:

$$\widetilde{t} = t + \epsilon, \qquad \widetilde{r} = r, \qquad \widetilde{u} = u, \qquad \widetilde{f_\alpha} = f_\alpha, \qquad \widetilde{E} = E.$$

This symmetry follows from the fact that coefficients of equations (5) do not depend on variable t. The G_2 and G_3 generate the following scaling transformations:

$$\widetilde{t} = t\exp(-\epsilon), \qquad \widetilde{r} = r\exp(-2\epsilon), \qquad \widetilde{u} = u\exp(-\epsilon), \qquad \widetilde{f_\alpha} = f_\alpha \exp(5\epsilon), \qquad \widetilde{E} = E,$$

and

$$\widetilde{t} = t\exp(-3\epsilon), \qquad \widetilde{r} = r\exp(-\epsilon), \qquad \widetilde{u} = u\exp(2\epsilon), \qquad \widetilde{f_\alpha} = f_\alpha, \qquad \widetilde{E} = E\exp(5\epsilon).$$

The lack of Galilean symmetry and spatial translational symmetry, contrary to the case of one-dimensional rectilinear motion [6–8], follows from the fact that for radial motion there exists the distinguished frame of reference connected with the point $r = 0$.

3 Classification of invariant solutions

Using the adjoint representation we find the optimal system of one-dimensional subalgebras (see [9, 10]). They are generated by the following operators:

$$G_1, \quad G_2, \quad G_3, \quad \pm G_1 - 3G_2 + G_3, \quad a_2 G_2 + a_3 G_3 \ \text{ for arbitrary } a_2, a_3 \neq 0.$$

Since G_2 commutes with G_3, we can express the finite transformations corresponding to the generator $a_2 G_2 + a_3 G_3$ as compositions of one-dimensional subgroups generated by operators G_2

and G_3. Similarly, because $[\pm G_1, -3G_2 + G_3] = 0$ the finite transformation corresponding to $\pm G_1 - 3G_2 + G_3$ is a composition of subgroups generated by G_1, G_2 and G_3. Using these transformations we find invariants built from independent and dependent variables. From these invariants follow the forms of invariant solutions corresponding to the optimal system. For example,

$$e^{\epsilon(\pm G_1 - 3G_2 + G_3)} = e^{\epsilon \pm G_1} e^{\epsilon(G_3 - 3G_2)} = e^{\pm \epsilon G_1} e^{-3\epsilon G_2} e^{\epsilon G_3}$$

leads to the following transformation

$$\widetilde{t'} = t' e^{\pm\epsilon}, \qquad \widetilde{r} = r e^{5\epsilon}, \qquad \widetilde{u} = u e^{5\epsilon}, \qquad \widetilde{f_\alpha} = f_\alpha e^{-15\epsilon}, \qquad \widetilde{E} = E e^{5\epsilon},$$

where $t' = e^t$. Invariants have the forms

$$r e^{\mp 5t}, \quad u e^{\mp 5t}, \quad r u^{-1}, \quad f_\alpha e^{\pm 15t}, \quad r^3 f_\alpha, \quad u^3 f_\alpha, \quad E e^{\mp 5t}, \quad r^{-1} E, \quad u^{-1} E, \quad \ldots.$$

We choose independent invariants (two of them built from independent variables – see [11])

$$y = r e^{\mp 5t}, \qquad z = u e^{\mp 5t}, \qquad f_{\alpha 0} = f_\alpha e^{\pm 15t}, \qquad E_0 = E e^{\mp 5t}$$

and look for solutions in the form

$$f_\alpha = e^{\mp 15t} f_{\alpha 0}\big(r e^{\mp 5t}, u e^{\mp 5t}\big), \qquad E = e^{\pm 5t} E_0\big(r e^{\mp 5t}\big),$$

because electric field does not depend on velocity u.

The results of this classification of essentially independent invariant solutions are gathered in the following table

No	Subgroup	Form of the solution
1	G_1	$f_\alpha(r,u)\,,\ E(r)$
2	G_2	$t^{-5} f_\alpha\big(t^2 r^{-1}, r^{-1}u^2\big), \quad E\big(t^2 r^{-1}\big)$
3	G_3	$f_\alpha\big(t r^{-3}, r^{-1}u^2\big), \quad t^{-1} r^{-2} E\big(t r^{-3}\big)$
4	$\pm G_1 - 3G_2 + G_3$	$e^{\mp 15t} f_\alpha\big(r e^{\mp 5t}, u e^{\mp 5t}\big), \quad e^{\pm 5t} E\big(r e^{\mp 5t}\big)$
5	$a_2 G_2 + a_3 G_3$	$r^{-2} u f_\alpha\big(t^{(2a_2+a_3)} r^{-(a_2+3a_3)}, t r^{-1} u\big),$ $t^{-2} r E\big(t^{(2a_2+a_3)} r^{-(a_2+3a_3)}\big)$

For example, stationary solutions $f_\alpha(r,u)$, $E(r)$ corresponding to G_1 are generalizations of nonlinear electrostatic BGK-waves (Bernstein, Greene, Kruskal [15]). The BGK-solutions are found by solving an integro-differential equation for electrostatic potential. This equation, which is obtained [2] by substituting the general solution of the Vlasov equation into the Poisson equation, is now more complicated due to the term $2Er^{-1}$. In the case of vanishing field $E = 0$ we obtain the equilibrium solutions of the same form as in the rectilinear case: $f_\alpha(u)$, where f_α is an arbitrary function.

4 Conclusions

The results obtained in this paper provide a new example of effectiveness of the method presented in [6–8]. Namely, we have found symmetry groups for Vlasov–Maxwell equations for spherically symmetric systems of multi-component collisionless plasma. The optimal system

of one-parameter subgroups is found and classification of corresponding invariant solutions is carried out.

Spherical symmetry of our problem leads to determining equations, which are different from the case of one-dimensional rectilinear motion due to higher powers of velocity in the Vlasov–Maxwell equations.

The symmetry group is narrower, only three-dimensional, than the symmetry group for one-dimensional rectilinear case [6,7,14]. The lack of the Galilean symmetry and spatial translational symmetry for the radial case is obvious since for radial motion there exists the distinguished frame of reference connected with the point $r = 0$. Other differences are of minor importance.

Conformal Maps and Integrable Hamiltonian Structures

Eugene BELOKOLOS

Dept. Theor. Physics, Institute of Magnetism, 36-b Vernadskii Ave., 03142 Kyiv, Ukraine
E-mail: *bel@imag.kiev.ua*

A discussion of integrable structures of complex analysis is presented. It is shown that a conformal map $z(w)$ of the exterior of the unit disc to the exterior of a simply-connected domain and a map $\overline{z}\big(w^{-1}\big)$ are conjugate variables with respect to some Poisson structure. Deformations of the functions $z(w)$, $\overline{z}\big(w^{-1}\big)$ with respect to the harmonic moments of the domain are described by the Hamiltonian equations. These equations are known as the Lax–Sato equations.

1 Introduction

Basic notions of the complex analysis and the physics have deep inter-connections. It is well known that an analytic function of complex variable may be considered as a complex potential of plane vector field and this fact leads to construction of the conformal field theory. But it is less known that a conformal map may be considered as an integrable Hamiltonian system, although this connection between complex analysis and mechanics was established some years ago. In our report we present a pedagogical introduction to this problem.

2 Moments of a curve (domain). Generating function of moments

We designate a curve on complex plane z as a closed analytic curve if it is an analytic image of circle, i.e. if it is parametrized by a function $z(w)$ that is analytic in a ring $a < |w| < b$ containing a circle $|w| = 1$.

Let us consider on a complex plane z a closed analytic curve Γ and designate by D_+ and D_- internal and external domains with respect to this curve. We shall assume that the point $z = 0$ belongs to the domain D_+.

For the curve Γ (or domains D_+ and D_-) we introduce two sets of the harmonic moments, namely, the external moments $\{t_0, t_1, \ldots\}$,

$$t_0 = \frac{1}{\pi}\int_{D_-} \mathrm{d}^2 z, \qquad t_k = -\frac{1}{\pi k}\int_{D_-} z^{-k}\mathrm{d}^2 z, \qquad k \geq 1,$$

and the internal moments $\{v_0, v_1, \ldots\}$,

$$v_0 = \frac{2}{\pi}\int_{D_+} \log|z|\mathrm{d}^2 z, \qquad v_k = \frac{1}{\pi}\int_{D_+} z^k \mathrm{d}^2 z, \qquad k \geq 1.$$

Moments t_0, v_0 are real numbers, other moments are complex numbers.

Let us introduce a generating function of moments F and τ-function

$$F = \log\tau = -\frac{1}{\pi}\int_{D_+}\mathrm{d}^2 z \int_{D_+}\mathrm{d}^2 z' \log\left|\frac{1}{z} - \frac{1}{z'}\right|.$$

The following theorem is valid.

Theorem 1. *A differential of the generating function of moments F (or the logarithm of τ-function) is of a form*

$$\mathrm{d}F = \mathrm{d}\log\tau = v_0\mathrm{d}t_0 + \sum_{k=1}^{\infty}\left(v_k\mathrm{d}t_k + \overline{v}_k\mathrm{d}\overline{t}_k\right),$$

and it allows to express the internal moments in terms of external ones,

$$v_0 = \frac{\partial F}{\partial t_0} = \frac{\partial\log\tau}{\partial t_0}, \qquad v_k = \frac{\partial F}{\partial t_k} = \frac{\partial\log\tau}{\partial t_k}, \qquad \overline{v}_k = \frac{\partial F}{\partial \overline{t}_k} = \frac{\partial\log\tau}{\partial \overline{t}_k}.$$

Thus, the sets of external and internal moments are not independent, there is connection between them. Any of these sets of moments defines uniquely the curve Γ (or domains D_+ and D_-) [1–3].

3 The Schwarz function $S(z)$ and its potential $\Omega(z)$

Let us present the equation $g(x,y)=0$ of an analytic curve Γ in complex coordinates, $g(\frac{z+\overline{z}}{2}, \frac{z-\overline{z}}{2i}) = 0$, and resolve the latter one with respect to the variable z. We obtain the equation of the curve Γ in the following form

$$\overline{z} = S(z).$$

The function $S(z)$ is called the Schwarz function of the curve Γ. This function is analytic in a strip that contains the curve [4].

The Schwarz function maps a point z into the conjugate one $S(z)$ with respect to the curve Γ. On the curve itself the Schwarz function coincides obviously with the complex conjugation.

According to definition the Schwarz function cannot be an arbitrary one, it must satisfy the so called unitary condition

$$z = \overline{S}(S(z)),$$

i.e. the inverse function must coincide with with the complex conjugated one. We remark here that if a function $f(z)$ is defined with the Laurent series $f(z) = \sum_j f_j z^j$, then $\overline{f}(z) = \sum_j \overline{f}_j z^j$.

Theorem 2. *The Laurent series for the Schwarz function $S(z)$ of a curve Γ is of the form*

$$S(z) = \sum_{k=-\infty}^{\infty} s_k z^{k-1} = \sum_{k=1}^{\infty} k t_k z^{k-1} + \frac{t_0}{z} + \sum_{k=1}^{\infty} v_k z^{-k-1},$$

i.e. the Laurent series coefficients of the Schwarz function are expressed in terms of the moments of the curve.

Proof. Let us assume that a function $f(z)$ is analytic in the domain $D_\pm$. Then for the function $g(z) = f(z)\overline{z} = f(z)S(z)$ the Green–Ostrogradskii formula

$$\int_{D_\pm}\frac{\partial g(z)}{\partial\overline{z}}\mathrm{d}^2 z = \pm\frac{1}{2i}\int_\Gamma g(z)\mathrm{d}z,$$

leads to the relation

$$\int_{D_\pm} f(z)\mathrm{d}^2 z = \pm\frac{1}{2i}\int_\Gamma f(z)S(z)\mathrm{d}z.$$

Using this formula in the case $f(z) = z^k$, $k \in \mathbb{Z}$, we can express the moments of curve Γ in terms of the Schwarz function $S(z)$,

$$t_k = \frac{1}{2\pi i k} \int_\Gamma z^{-k} S(z) \mathrm{d}z, \qquad v_k = \frac{1}{2\pi i} \int_\Gamma z^k S(z) \mathrm{d}z.$$

Substituting in integrals the Schwarz function in the form of its Laurent series,

$$S(z) = \sum_{k=-\infty}^{\infty} s_k z^{k-1}$$

and calculating integrals by means of the orthogonality relation

$$\frac{1}{2\pi i} \int_\Gamma z^j \mathrm{d}z = \delta_{j,-1},$$

we obtain

$$s_0 = t_0, \qquad s_k = k t_k, \qquad s_{-k} = v_k, \qquad k \geq 1.$$

Thus the moments of the curve Γ are the coefficients of the Laurent series for the Schwarz function $S(z)$,

$$S(z) = \sum_{k=-\infty}^{\infty} s_k z^{k-1} = \sum_{k=1}^{\infty} k t_k z^{k-1} + \frac{t_0}{z} + \sum_{k=1}^{\infty} v_k z^{-k-1}. \qquad \blacksquare$$

Now we introduce the function $\Omega(z)$ that is a potential for the Schwarz function,

$$S(z) = \partial_z \Omega(z).$$

According to definition we can present the function $\Omega(z)$ in a form of the Laurent series,

$$\Omega(z) = \sum_{k=1}^{\infty} t_k z^k - \frac{1}{2} v_0 + t_0 \log z - \sum_{k=1}^{\infty} \frac{v_k}{k} z^{-k},$$

and hence as a sum of the following functions,

$$\Omega(z) = \Omega^{(+)}(z) + \Omega^{(-)}(z) - \frac{1}{2} v_0,$$

where the functions $\Omega^{(\pm)}(z)$ are analytic in domains $D_\pm$ appropriately. Here we have used the notations

$$\Omega^{(+)}(z) = \sum_{k=1}^{\infty} t_k z^k = \frac{1}{\pi} \int_{D_-} \log\left(1 - \frac{z}{z'}\right) \mathrm{d}^2 z',$$

$$\Omega^{(-)}(z) = t_0 \log z - \sum_{k=1}^{\infty} \frac{v_k}{k} z^{-k} = \frac{1}{\pi} \int_{D_+} \log\left(z - z'\right) \mathrm{d}^2 z'.$$

At the curve Γ we can write down the potential $\Omega(z)$ in the form

$$\Omega(z) = \frac{1}{2}|z|^2 + i 2A(z), \qquad z \in \Gamma,$$

where $|z|$ is the distance from the origin of coordinates to the point z, and $A(z)$ is the area of the domain D_+, bounded with a ray $\phi = \arg z$ and a real line.

The following theorem is valid.

Theorem 3. *The differential of the function $\Omega(z)$ is of the form*

$$\mathrm{d}\Omega = S\mathrm{d}z + \log w\,\mathrm{d}t_0 + \sum_{k=1}^{\infty}\left(H_k\,\mathrm{d}t_k - \overline{H}_k\,\mathrm{d}\overline{t}_k\right),$$

where

$$H_k(z) = \partial_{t_k}\Omega(z) = \left(z^k(w)\right)_+ + \frac{1}{2}\left(z^k(w)\right)_0,$$

$$\overline{H}_k(z) = -\partial_{\overline{t}_k}\Omega(z) = -\left(\overline{z}^k(w)\right)_- - \frac{1}{2}\left(\overline{z}^k(w)\right)_0.$$

Here the symbol $(f(w))_\pm$ designates the part of the Laurent series that contains summands only with positive (negative) powers w, and $(f(w))_0$ designates the summand with w^0.

4 Conformal maps as Hamiltonian systems with respect to moments

Let us consider the disc of unit radius $U(0,1)$ on a plane w, and the domain D on a plane z. Let us consider the univalent analytic function $z(w)$, that maps conformally a complement of the unit disc to a complement of the domain D. In order to emphasize a dependence of this function on the domain D it would be reasonable to write down the function in the form $z(w,D)$ or $z(w,t_0,t_1,\ldots)$ since moments $(t_0,t_1,\ldots)$ of the domain D define it uniquely. We shall use the latter designation.

For arbitrary functions $f(w,t_0)$, $g(w,t_0)$ let us define the Poisson brackets as follows

$$\{f,g\} = \frac{\partial f}{\partial \log w}\frac{\partial g}{\partial t_0} - \frac{\partial g}{\partial \log w}\frac{\partial f}{\partial t_0} = w\left(\frac{\partial f}{\partial w}\frac{\partial g}{\partial t_0} - \frac{\partial g}{\partial w}\frac{\partial f}{\partial t_0}\right).$$

It is easy to verify that according to definition these Poisson brackets have the following properties:

1)Antisymmetry

$$\{f,g\} = -\{g,f\},$$

2) Linearity

$$\{f_1+f_2,g\} = \{f_1,g\} + \{f_2,g\},$$

3) The Jacobi identity

$$\{f,\{g,h\}\} = \{g,\{h,f\}\} = \{h,\{f,g\}\}.$$

We can present the functions

$$z(w) = \overline{S}\left(\overline{z}\left(w^{-1}\right)\right), \qquad \overline{z}\left(w^{-1}\right) = S(z(w)),$$

by means of series

$$z(w) = rw + \sum_{j=0}^{\infty} u_j w^{-j}, \qquad \overline{z}\left(w^{-1}\right) = rw^{-1} + \sum_{j=0}^{\infty}\overline{u}_j w^j,$$

where r is the so called conformal radius.

Using the latter expressions we can prove the following theorem.

Theorem 4 ([5]). *A pair of variables* $(\log w, t_0)$ *and* $\big(z(w,t_0), \overline{z}\big(w^{-1},t_0\big)\big)$ *are canonical variables with respect to the Poisson brackets defined above,*

$$\big\{z(w,t_0), \overline{z}\left(w^{-1},t_0\right)\big\} = 1.$$

Proof. According to definition of the Poisson bracket

$$\big\{z(w,t_0), \overline{z}\left(w^{-1},t_0\right)\big\} = w\left(\frac{\partial z(w,t_0)}{\partial w}\frac{\partial \overline{z}\left(w^{-1},t_0\right)}{\partial t_0} - \frac{\partial \overline{z}\left(w^{-1},t_0\right)}{\partial w}\frac{\partial z(w,t_0)}{\partial t_0}\right).$$

Now using the formula $\overline{z}\big(w^{-1},t_0\big) = S(z(w,t_0))$ we get

$$\frac{\partial \overline{z}\left(w^{-1},t_0\right)}{\partial t_0} = \frac{\partial S(z,t_0)}{\partial t_0} + \frac{\partial S(z,t_0)}{\partial z}\frac{\partial z(w,t_0)}{\partial t_0}, \qquad \frac{\partial \overline{z}\left(w^{-1},t_0\right)}{\partial w} = \frac{\partial S(z,t_0)}{\partial z}\frac{\partial z(w,t_0)}{\partial w},$$

and substituting these expressions in the Poisson bracket we obtain the equality

$$\big\{z(w,t_0), \overline{z}\left(w^{-1},t_0\right)\big\} = w\frac{\partial S(z,t_0)}{\partial t_0}\frac{\partial z(w,t_0)}{\partial w}.$$

The r.h.s. of this equality due to

$$S(z) = \sum_{k=1}^{\infty} k t_k z^{k-1} + \frac{t_0}{z} + \sum_{k=1}^{\infty} v_k z^{-k-1}, \qquad \text{and} \qquad z(w) = rw + \sum_{j=0}^{\infty} u_j w^{-j},$$

is 1 plus positive powers in w.

Similarly using the formula $z(w) = \overline{S}\big(\overline{z}\big(w^{-1}\big)\big)$, we prove that

$$\big\{z(w,t_0), \overline{z}\left(w^{-1},t_0\right)\big\} = -w\frac{\partial \overline{S}(\overline{z},t_0)}{\partial t_0}\frac{\partial \overline{z}\left(w^{-1},t_0\right)}{\partial w}.$$

The r.h.s. of this equality due to

$$\overline{S}(z) = \sum_{k=1}^{\infty} k \overline{t}_k z^{k-1} + \frac{t_0}{z} + \sum_{k=1}^{\infty} \overline{v}_k z^{-k-1}, \qquad \text{and} \qquad \overline{z}\left(w^{-1}\right) = rw^{-1} + \sum_{j=0}^{\infty} \overline{u}_j w^{j},$$

is 1 plus negative powers of w.

Comparing two expressions for the Poisson bracket we prove the theorem. ■

Thus we established the symplectic structure of the conformal map.

Theorem 5 ([5]). *The deformation of the conformal map* $z(w)$ *as a result of variation of moments* $\{t_k\}_{k=0}^{\infty}$ *is described with the so called Lax–Sato equations*

$$\frac{\partial z(w)}{\partial t_k} = \{H_k, z(w)\}, \qquad \frac{\partial \overline{z}\left(w^{-1}\right)}{\partial t_k} = \left\{H_k, \overline{z}\left(w^{-1}\right)\right\}.$$

Self-consistency conditions of the Lax–Sato equations are

$$\partial_{t_k} H_l - \partial_{t_l} H_k + \{H_k, H_l\} = 0.$$

5 An example: ellipse

Let us consider an example when the curve Γ is ellipse and is characterized with three external moments t_0, t_1, t_2, all other moments are equal to zero, $t_3 = t_4 = \cdots = 0$.

An ellipse with center at a point $z = 0$ and half-axes a, b along coordinate axes x, y is described by the equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} = 1.$$

Three non-zero external moments of the ellipse in terms of half-axes a, b looks as follows,

$$t_0 = ab, \qquad t_1 = 0, \qquad t_2 = \frac{1}{2}\frac{a-b}{a+b}.$$

All internal moments of the ellipse are non-zero and the first two of them are of the following form,

$$v_1 = 0, \qquad v_2 = \frac{2t_0^2 t_2}{1-4t_2^2}.$$

The Schwarz function of ellipse is

$$S(z) = \frac{a^2+b^2}{a^2-b^2}z - \frac{2ab}{a^2-b^2}\sqrt{z^2-(a^2-b^2)},$$

and its Laurent series looks as follows,

$$S(z) = 2t_2 z + \frac{t_0}{z} + \frac{v_2}{z^3} + \cdots .$$

A logarithm of τ-function is

$$\log\tau = \frac{1}{2}t_0^2\left(\log\frac{t_0}{1-t_2^2} - \frac{3}{2}\right).$$

The conformal map of a complement of unit disc to a complement of ellipse is the function

$$z(w) = rw + u_1 w^{-1}$$

with coefficients

$$r^2 = \frac{t_0}{1-4t_2^2} = \frac{1}{4}(a+b)^2, \qquad u_1^2 = \frac{4t_0 t_2^2}{1-4t_2^2} = \frac{1}{4}(a-b)^2.$$

The first two Hamiltonians are

$$H_1 = rw, \qquad H_2 = r^2 w^2 + u_1 r,$$

and the appropriate Hamiltonian flows do not change the form of disc. The Lax–Sato equations with the Hamiltonians $H_3, H_4, \ldots$ describe a deformation of the disc into the ellipse.

6 The Dirichlet boundary problem

The Dirichlet boundary problem

$$\Delta u(z) = 4\partial_z \partial_{\overline{z}} u(z) = f(z), \quad z \in D; \qquad u(z)|_{\partial D} = g(z),$$

has a solution

$$u(z) = \frac{1}{2\pi} \iint_D f(\zeta) G(z,\zeta) \mathrm{d}\zeta \mathrm{d}\overline{\zeta} + \frac{1}{2\pi} \int_{\partial D} g(\zeta) \frac{\partial}{\partial n} G(z,\zeta) |\mathrm{d}\zeta|,$$

where $G(z,\zeta)$ is the Green function which is uniquely defined by the following properties:

1) $G(z,\zeta) - \log|z-\zeta|$ is a symmetric, bounded and harmonic function in both arguments everywhere in the domain D,

2) $G(z,\zeta) = 0$ if any one of their arguments is at the boundary of the domain D.

We can present the Green function by the expression

$$G(z,\zeta) = |w(z,\zeta)|,$$

where $w(z,\zeta)$ is the analytic function which describe a conformal map of the domain D to the unit disc U.

According to J. Hadamard [6, 7] variations of the Green function under small deformations of the domain looks as follows

$$\delta G(z,\zeta) = \frac{1}{2\pi} \int_{\partial D} \partial_n G(z,\eta) \partial_n G(\zeta,\eta) \delta h(\eta) |\mathrm{d}\eta|,$$

where $\delta h(\eta)$ is a shift from the curve ∂D to the deformed curve along the normal n at the point $\eta \in \partial D$.

It is possible to write down the deformations $\delta h(\eta)$ of the domain boundary in terms of harmonic moments of the domain and as a result of that to express the variations of the Green function in these terms.

7 Quantization

Now let us quantize the above Hamiltonian structure and introduce respectively basic quantities of the quantized theory.

The Lax operators are

$$L = r(t_0) \exp\left(\hbar \frac{\partial}{\partial t_0}\right) + \sum_{k=0}^{\infty} u_k(t_0) \exp\left(-k\hbar \frac{\partial}{\partial t_0}\right),$$

$$\overline{L} = \exp\left(-\hbar \frac{\partial}{\partial t_0}\right) r(t_0) + \sum_{k=0}^{\infty} \exp\left(k\hbar \frac{\partial}{\partial t_0}\right) \overline{u}_k(t_0).$$

The Hamiltonians are

$$H_k = \left(L^k\right)_+ + \frac{1}{2}\left(L^k\right)_0, \qquad \overline{H}_k = \left(\overline{L}^k\right)_- + \frac{1}{2}\left(\overline{L}^k\right)_0,$$

where the symbol $\left(L^k\right)_{\pm}$ means positive (negative) parts of series for the shift operator $\exp\left(\hbar \frac{\partial}{\partial t_0}\right)$.

The Lax–Sato equations attain now the following form

$$\hbar \frac{\partial L}{\partial t_k} = [H_k, L], \qquad \hbar \frac{\partial L}{\partial \overline{t}_k} = [\overline{H}_k, L].$$

The spectrum of Lax operator is defined by the equation

$$L\Psi = z\Psi,$$

and the appropriate wave function can be presented as follows,

$$\Psi(z,t_0,t_1,\ldots) = z^{\hbar^{-1}t_0}\tau_\hbar^{-1}(t_0,t_1,\ldots)\exp\left(\frac{1}{\hbar}\sum_{k>0}t_kz^k\right)\exp\left(\hbar\sum_{k>0}\frac{z^{-k}}{k}\frac{\partial}{\partial t_k}\right)\tau_\hbar(t_0,t_1,\ldots).$$

By means of the last expression we introduce the function

$$\tau_\hbar(t_0,t_1,\ldots).$$

The commutator

$$[L,\overline{L}] = \hbar$$

is called the selection rule or the string equation

In the semiclassical limit $\hbar \to 0$ we get the following correspondence with the notions considered above:

$$W = \exp\left(\hbar\frac{\partial}{\partial t_0}\right) \to w, \qquad L \to z(w),$$
$$\Psi \to \exp\left(\frac{\Omega}{\hbar}\right), \qquad \tau_\hbar \to \exp\left(\log\frac{\tau}{\hbar^2}\right),$$
$$\frac{1}{\hbar}[L,\overline{L}] = 1 \to \left\{z(w),\overline{z}\left(w^{-1}\right)\right\} = 1.$$

Integration of Bi-Hamiltonian Systems by Using the Dressing Method

Yuriy BERKELA

Carpathian Biosphere Reserve, Rakhiv, Ukraine
E-mail: *yuri@rakhiv.ukrtel.net*

The integration by the dressing method of integrable by Lax systems from the $\mathcal{D}$HcmKP hierarchy is considered. The applicability of this method to construction of exact solutions of the nonlinear bi-Hamiltonian systems, also with nonstandart (recursive) Lax representations, is shown.

1 Introduction

The paper [1] introduces the so-called scalar $\mathcal{D}$-Hermitian constrained modified Kadomtsev–Petviashvili ($\mathcal{D}$HcmKP) hierarchy. The integrable systems of this hierarchy contain already known nonlinear models of the soliton theory and their new modifications and vector (multi-component) generalizations. The unified form of the Lax operator (4) allows to construct a general method of the Lax flows investigation describing a group of transformation operators (group of $\mathcal{D}$-unital Volterra operators) which corresponds to the Lie algebra of the integro-differential symbols of $\mathcal{D}$-skew-Hermitian operators.

This paper continues integration of integrable systems from $\mathcal{D}$HcmKP by using the method of dressing transformations. For $n = 2$, under additional reduction, Lax operator (4) becomes the generating operator for the modified Korteweg–de Vries equation (mKdV) in a real case. The vector generalization of the mKdV equation can be reduced to common Korteweg–de Vries equation (KdV).

In Section 2 we submit basic definitions in the $\mathcal{D}$HcmKP hierarchy and reductions to well-known dynamical systems.

In Sections 3 we propose the method of construction of exact solutions for the KdV equation and the mKdV equation.

2 $\mathcal{D}$HcmKP hierarchy and its reductions

Let us consider the algebra ζ of the micro-differential operators [2],

$$\zeta := \left\{ L = \sum_{i=-\infty}^{n(L)} a_i \mathcal{D}^i : \ a_i = a_i(x, y, t_m); \ i, n(L) \in \mathbb{Z} \right\}.$$

The coefficients a_i are, in general, smooth $(N \times N)$-matrix-valued functions of $x \in \mathbb{R}$ and of finite quantity of the evolution parameters $t_m \in \mathbb{R}$, $t_2 := y$, $t_3 := t$. The micro-differential operator $L \in \zeta$ satisfies additional constraints. The Hermitian-conjugated operator $L^* := \sum\limits_{i=-\infty}^{n(L)} (-1)^i \mathcal{D}^i a_i^*$, where $a_i^* = \bar{a}^\top$, $(\alpha \partial_y)^* := -\bar{\alpha}\partial_y$, $(\beta \partial_{t_m})^* := -\bar{\beta}\partial_{t_m}$.

Definition 1. We say that an operator $L \in \zeta$ is $\mathcal{D}$-Hermitian ($\mathcal{D}$-skew-Hermitian) if $L^* = \mathcal{D}L\mathcal{D}^{-1}$ ($L^* = -\mathcal{D}L\mathcal{D}^{-1}$).

Definition 2. We say that an integral operator $W \in \zeta_{<1} := \left\{ L_{<1} := \sum\limits_{i=-\infty}^{0} u_i \mathcal{D}^i \right\}$ is $\mathcal{D}$-unital if $W^{-1} = \mathcal{D}^{-1} W^* \mathcal{D}$.

Lemma 1 ([1]). *Let L be a $\mathcal{D}$-Hermitian ($\mathcal{D}$-skew-Hermitian) operator and W is a $\mathcal{D}$-unital operator. Then $\hat{L} := WLW^{-1}$ is a $\mathcal{D}$-Hermitian ($\mathcal{D}$-skew-Hermitian) operator.*

Let $\varphi = \varphi(x, y, t_m)$ be a matrix $N \times K$ function, $\Omega := C + \int_{-\infty}^{x} \varphi^* \varphi_x dx$ be a non-degenerate $K \times K$ function such that the improper integral $\int_{-\infty}^{x} \varphi^* \varphi_x dx$ converges absolutely, C be a constant complex $K \times K$-matrix.

Theorem 1 ([1]). 1. *Let $C^* = -C = \text{const} \in \text{Mat}_{K\times K}(\mathbb{C})$ and $w_0 := I_N - \varphi \Omega^{-1} \varphi^*$ (where I_N is a unitary $(N \times N)$-matrix. Then $w_0^{-1} = w_0^* = I_N - \varphi \Omega^{*-1} \varphi^*$, where $\Omega^* = \varphi^* \varphi - \Omega$.*

2. *Operator $W := w_0 + \varphi \Omega^{-1} \mathcal{D}^{-1} \varphi_x^*$ is a $\mathcal{D}$-unital and the inverse operator is defined by the formula $W^{-1} := w_0^{-1} + \varphi \mathcal{D}^{-1} (\Omega^{*-1} \varphi^*)_x$.*

Lemma 2 ([3]). *The following property holds true:*

$$\det w_0 = (-1)^K \frac{\det \Omega^*}{\det \Omega}.$$

Remark 1. Let $\varphi \in \text{Mat}_{N\times K}(\mathbb{R})$ and $C^\top = -C$. Then $\det w_0 = \det(I_N - \varphi \Omega^{-1} \varphi^\top) = (-1)^K$.

Let us consider the modified Korteweg–de Vries equation (mKdV)

$$u_t = u_{xxx} + a u^2 u_x,$$

where $u = u(x, t) \in C^{(\infty)}(\mathbb{R}^2, \mathbb{R})$.

$$u_t = \mathcal{L}(\nabla H_1) = \mathcal{M}(\nabla H_2),$$

where $\mathcal{L} = -\mathcal{D}$, $\mathcal{M} = \mathcal{D}^3 + \frac{2}{3} a u \mathcal{D} u \mathcal{D}^{-1} u \mathcal{D}$ is a Hamiltonian pair and the functionals

$$H_1 = \int_{\mathbb{R}} \left(\frac{1}{2} u_x^2 - \frac{1}{12} a u^4 \right) dx, \qquad H_2 = \int_{\mathbb{R}} \frac{1}{2} u^2 dx$$

are first integrals of the mKdV equation.

The generation operators $\Lambda_{\text{mKdV}} = \mathcal{L}^{-1} \mathcal{M}$ and $\Lambda^\tau_{\text{mKdV}} = \mathcal{M} \mathcal{L}^{-1}$ have the form

$$\Lambda = -\mathcal{D}^2 - \frac{2}{3} a u \mathcal{D}^{-1} u \mathcal{D}, \qquad \Lambda^\tau = -\mathcal{D}^2 - \frac{2}{3} a \mathcal{D} u \mathcal{D}^{-1} u \tag{1}$$

and satisfy the equation of Lax type $\Lambda_{t_m} = [\Lambda, K'^\tau]$, where $K'^\tau = -\mathcal{D}^3 - a u \mathcal{D}$.

Let us consider also the KdV equation

$$u_t = u_{xxx} + a u u_x = K[u]. \tag{2}$$

Similarly to the previous equation, the operators will have the form

$$\begin{aligned} &\Lambda_{\text{KdV}} = \mathcal{D}^2 + \frac{2}{3} a u - \frac{1}{3} a \mathcal{D}^{-1} u_x, \qquad \Lambda^\tau_{\text{KdV}} = \mathcal{D}^2 + \frac{2}{3} a u + \frac{1}{3} a u_x \mathcal{D}^{-1}, \\ &K' = \mathcal{D}^3 + a u \mathcal{D} + a u_x, \qquad K'^\tau = -\mathcal{D}^3 - a u \mathcal{D}. \end{aligned} \tag{3}$$

The operators Λ, K'^τ are $\mathcal{D}$-Hermitian and $\mathcal{D}$-skew-Hermitian respectively. These operators are partial cases of the $\mathcal{D}$-Hermitian constrained modified Kadomtsev–Petviashvili ($\mathcal{D}$HcmKP) hierarchy introduced in the paper [1] and determined in the following form: let

$$\zeta \ni L_{\mathcal{D}\text{HcmKP}} := L_n = \mathcal{D}^n + u_{n-1} \mathcal{D}^{n-1} + \cdots + u_1 \mathcal{D} - \boldsymbol{q} \mathcal{M} \mathcal{D}^{-1} \boldsymbol{q}^* \mathcal{D}, \tag{4}$$

$\mathcal{M}^* = (-1)^n\mathcal{M}$ is a complex constant $(l \times l)$-matrix, $\boldsymbol{q}(x, t_m) = (q_1, \dots, q_l)$, $k, l \in \mathbb{N}$, and an additional reduction for operator L_n: $L_n^* = \mu\mathcal{D}L_n\mathcal{D}^{-1}$, $\mu = \pm 1$.

We consider the evolution equations

$$\alpha_m L_{n_{t_m}} = [B_m, L_n], \tag{5}$$

where $L_n := L_{\mathcal{D}\mathrm{HcmKP}}$, and B_m are fractional powers m/n of L_n; $n, m \in \mathbb{N}$.

Let $n = 2$. For $L_2 = \mathcal{D}^2 + iu\mathcal{D} - \boldsymbol{q}\mathcal{M}\mathcal{D}^{-1}\boldsymbol{q}^*\mathcal{D}$ we obtain that $B_2 = (L_2)_{>0} = \mathcal{D}^2 + iu\mathcal{D}$, $B_3 = \mathcal{D}^3 + \frac{3}{2}iu\mathcal{D}^2 - \left(\frac{3}{8}u^2 - \frac{3i}{4}u_x + \frac{3}{2}\boldsymbol{q}\mathcal{M}\boldsymbol{q}^*\right)\mathcal{D}$, $\mathcal{M}^* = \mathcal{M}$. For $\alpha_2 = i$, $\alpha_3 = 1$ the following systems of equations are consequences of (5)

$$i\boldsymbol{q}_{t_2} = \boldsymbol{q}_{xx} + iu\boldsymbol{q}_x, \qquad u_{t_2} = 2(\boldsymbol{q}\mathcal{M}\boldsymbol{q}^*)_x \tag{6}$$

and

$$\begin{aligned}
\boldsymbol{q}_{t_3} &= \boldsymbol{q}_{xxx} + \frac{3}{2}iu\boldsymbol{q}_{xx} - \left(\frac{3}{8}u^2 + \frac{3}{2}\boldsymbol{q}\mathcal{M}\boldsymbol{q}^* - \frac{3}{4}iu_x\right)\boldsymbol{q}_x,\\
u_{t_3} &= \frac{1}{4}u_{xxx} + \frac{3}{8}u^2u_x - \frac{3}{2}(\boldsymbol{q}\mathcal{M}\boldsymbol{q}^*u)_x + \frac{3}{2}i(\boldsymbol{q}_x\mathcal{M}\boldsymbol{q}^* - \boldsymbol{q}\mathcal{M}\boldsymbol{q}_x^*)_x.
\end{aligned} \tag{7}$$

System (6) is a multi-component modification of the integrable Yajima–Oikawa model [4], which describes the interaction of the Laengmur wave packets in the physics of plasma. System (2) is a modification of a higher Yajima–Oikawa model. Note that equation (2) admits some interesting reductions on invariant sub-manifolds, where evolution is introduced by known dynamical systems. So, for $\boldsymbol{q}\mathcal{M}\mathcal{D}^{-1}\boldsymbol{q}^*\mathcal{D} \equiv 0$ we have the scalar mKdV equation $u_{t_3} = \frac{1}{4}u_{xxx} + \frac{3}{8}u^2u_x$. For $u \equiv 0$ the complex multi-component mKdV equation obtained

$$\boldsymbol{q}_{t_3} = \boldsymbol{q}_{xxx} - \frac{3}{2}\boldsymbol{q}\mathcal{M}\boldsymbol{q}^*\boldsymbol{q}_x \tag{8}$$

with the differential condition

$$(\boldsymbol{q}\mathcal{M}\boldsymbol{q}_x^* - \boldsymbol{q}_x\mathcal{M}\boldsymbol{q}^*)_x = 0, \tag{9}$$

and for $\bar{\boldsymbol{q}} \equiv \boldsymbol{q}$, $\mathcal{M} \in \mathrm{Mat}_{l\times l}(\mathbb{R})$ its real version is

$$\boldsymbol{q}_{t_3} = \boldsymbol{q}_{xxx} - \frac{3}{2}\boldsymbol{q}\mathcal{M}\boldsymbol{q}^\top\boldsymbol{q}_x. \tag{10}$$

In this case, the differential constraint is satisfied.

Remark 2. The vector generalization of the complex mKdV equation can be obtained from system (8)–(9), if we satisfy condition (9) in such a way: let us $\boldsymbol{q} = (\vec{\boldsymbol{q}}, \bar{\vec{\boldsymbol{q}}})$, $\vec{\boldsymbol{q}} = (q_1, \dots, q_k)$ be a k-component vector-function ($l = 2k$) and the matrix $\mathcal{M}$ have a block form

$$\mathcal{M} = \begin{pmatrix} B & A \\ \bar{A} & \bar{B} \end{pmatrix}, \qquad A^\top = A, \qquad B^* = B. \tag{11}$$

Condition (9) is satisfied similarly.

3 Integration of some bi-Hamiltonian systems

Theorem 2. *Let:* 1) $\varphi(x, t_3)$ *be a real* K*-component solution of the system of equations*

$$\varphi_{t_3} = \varphi_{xxx}, \qquad \varphi_{xx} = \varphi\Lambda. \tag{12}$$

2) $C^\top = -C$ *is a real skew-symmetric matrix.*

3) *Matrix function* $\Omega := C + \int_{-\infty}^{x}\varphi^\top\varphi_x dx$ *is non-degenerate on the left semi-axis.*

Then the function $\boldsymbol{q}(x, t_3) := \varphi\Omega^{-1}$ *satisfies mKdV equation* (10)*, where* $\mathcal{M} = C\Lambda - \Lambda^\top C$.

Proof. Let $L_0 := \mathcal{D}^2$, then using Theorem 1

$$L := W\mathcal{D}^2W^{-1} = \mathcal{D}^2 - 2w_{0x}w_0^{-1}\mathcal{D} - \left[\varphi_{xx} - \varphi\Omega^{-1}\int_{-\infty}^{x}\varphi^*\varphi_{xxx}dx\right]\mathcal{D}^{-1}\Omega^{*-1}\varphi^*\mathcal{D}$$
$$- \varphi\Omega^{-1}\mathcal{D}^{-1}\left[\varphi^*_{xx} - \int_{-\infty}^{x}\varphi^*_{xxx}\varphi dx\Omega^{*-1}\varphi^*\right]\mathcal{D}.$$

Under conditions a)–b) we obtain that

$$L = \mathcal{D}^2 - 2w_{0x}w_0^{-1}\mathcal{D} - \varphi\Omega^{-1}(C\Lambda - \Lambda^*C)\mathcal{D}^{-1}\Omega^{*-1}\varphi^*\mathcal{D}.$$

Let $M_0 := \partial_{t_3} - \mathcal{D}^3$, similarly we proceed to the operator

$$M := WM_0W^{-1} = \partial_{t_3} - \mathcal{D}^3 + 3w_{0x}w_0^{-1}\mathcal{D}^2$$
$$- \left[w_0(w_0^{-1})_{xx} - 2w_0\varphi_{xx}\Omega^{*-1}\varphi^* - w_0\varphi_x(\Omega^{*-1}\varphi^*)_x\right.$$
$$\left.+ \varphi\Omega^{-1}\varphi^*_x(w_0^{-1})_x - \varphi\Omega^{-1}\varphi^*_{xx}w_0^{-1} - \varphi\Omega^{-1}\varphi^*_x\varphi_x\Omega^{*-1}\varphi^*\right]\mathcal{D}$$
$$- \left[\varphi_{t_3} - \varphi_{xxx} - \varphi\Omega^{-1}\int_{-\infty}^{x}\varphi^*(\varphi_{t_3} - \varphi_{xxx})_x dx\right]\mathcal{D}^{-1}\Omega^{*-1}\varphi^*\mathcal{D}$$
$$+ \varphi\Omega^{-1}\mathcal{D}^{-1}\left[\varphi^*_{t_3} - \varphi^*_{xxx} - \int_{-\infty}^{x}(\varphi^*_{t_3} - \varphi^*_{xxx})_x\varphi dx\Omega^{*-1}\varphi^*\right]\mathcal{D}.$$

Under condition a) the integral parts are equal to zero. With Remark 1 the formulas for the "dressed" operators L and M are:

$$L = \mathcal{D}^2 - \boldsymbol{q}\mathcal{M}\mathcal{D}^{-1}\boldsymbol{q}^\top\mathcal{D}, \qquad M := \partial_{t_3} - \mathcal{D}^3 + \frac{3}{2}\boldsymbol{q}\mathcal{M}\boldsymbol{q}^\top\mathcal{D}. \tag{13}$$

For $l = 1$ (that is $\boldsymbol{q} = q$ is a scalar function) the operators L and M (13) constitute the recursive Lax pair for the mKdV equation (1). ■

Let us consider Lax operators (13) for the K-component real mKdV equation (10),

$$[L, M] = 0 \;\Leftrightarrow\; \boldsymbol{q}_{t_3} = \boldsymbol{q}_{xxx} - \frac{3}{2}\boldsymbol{q}\mathcal{M}\boldsymbol{q}^\top\boldsymbol{q}_x = K[\boldsymbol{q}]. \tag{14}$$

The operator L is a K-generalization [5] of the generating operator Λ_{mKdV} (1) for the scalar mKdV equation and M^τ is its linearization ($M^\tau = \partial_{t_3} - K'[\boldsymbol{q}]$).

Let $K = 2k$, $\boldsymbol{q} = (\vec{\alpha}, \vec{\boldsymbol{q}})$, $\vec{\alpha} \in \mathbb{R}^k$, $\vec{\boldsymbol{q}} = \vec{\boldsymbol{q}}(x, t_3)$,

$$\mathcal{M} = \begin{pmatrix} 0 & -\Lambda^\top \\ -\Lambda & 0 \end{pmatrix}, \tag{15}$$

where Λ is a constant real $(k \times k)$-matrix. In this case, operators (13) reduce to the form

$$L = \mathcal{D}^2 - (\vec{\alpha}, \vec{\boldsymbol{q}})\mathcal{M}(\vec{\alpha}, \vec{\boldsymbol{q}})^\top + (\vec{\alpha}, \vec{\boldsymbol{q}})\mathcal{M}\mathcal{D}^{-1}(\vec{\alpha}, \vec{\boldsymbol{q}})^\top_x$$
$$= \mathcal{D}^2 + 2\vec{\alpha}\Lambda^\top\vec{\boldsymbol{q}}^\top - \mathcal{D}^{-1}(\vec{\alpha}\Lambda^\top\vec{\boldsymbol{q}}^\top)_x = \mathcal{D}^2 + 2u - \mathcal{D}^{-1}u_x =: \Lambda_{KdV}, \tag{16}$$
$$M = \partial_{t_3} - \mathcal{D}^3 - 3u\mathcal{D}, \tag{17}$$

where $u = \vec{\alpha}\Lambda^\top\vec{\boldsymbol{q}}^\top$, and constitute a recursive Lax pair for KdV equation (see (2)–(3) for $a = 3$)

$$[\partial_{t_3} + K'^\tau[u], \Lambda_{KdV}] = 0 \;\Leftrightarrow\; \frac{\partial}{\partial t_3}\Lambda_{KdV} = [\Lambda_{KdV}, K'^\tau]$$
$$\Leftrightarrow u_{t_3} = K[u] = u_{xxx} + 3uu_x. \tag{18}$$

Described process of reduction of the real version of the vector mKdV equation (14) to scalar KdV equation (18) allows to formulate the following statement.

Theorem 3. *Let:* 1) $\varphi(x,t_3)=(\vec{\varphi},\vec{\alpha})$, *where* $\vec{\varphi}=\vec{\varphi}(x,t_3)$ *is a* k*-component real field,* $\mathbb{R}^k\ni\vec{\alpha}$ *is a* k*-component real vector.*

2) $\vec{\varphi}$ *is a solution of the linear system*

$$\vec{\varphi}_{t_3}=\vec{\varphi}_{xxx},\qquad \vec{\varphi}_{xx}=\vec{\varphi}\Lambda,\qquad \Lambda\in \mathrm{Mat}_{k\times k}(\mathbb{R}).$$

3) $\Omega:=C+\int_{-\infty}^{x}\varphi^{\top}\varphi_x dx$ *is a non-degenerate on the left semi-axis* $(2k)\times(2k)$*-matrix function, where* $C=\begin{pmatrix}0 & I_k\\ -I_k & 0\end{pmatrix}$.

Then the function

$$u(x,t_3):=\vec{\alpha}\Lambda^{\top}(\vec{\varphi}^{\top}\vec{\alpha}-I_k)^{-1}\left(\vec{\varphi}^{\top}+\int_{-\infty}^{x}\vec{\varphi}_x^{\top}\vec{\varphi}\,dx\vec{\alpha}^{\top}\right)$$

is a solution of KdV equation (18).

Proof. We consider

$$\Omega:=C+\int_{-\infty}^{x}\varphi^{\top}\varphi_x\,dx=\begin{pmatrix}\displaystyle\int_{-\infty}^{x}\vec{\varphi}^{\top}\vec{\varphi}_x\,dx & I_k\\ \vec{\alpha}^{\top}\vec{\varphi}-I_k & 0\end{pmatrix}.$$

In order to prove the Theorem we use the known formula for the matrix A^{-1} that is inverse the matrix for the block $(2k)\times(2k)$-matrix A

$$A=\begin{pmatrix}A_{11} & A_{12}\\ A_{21} & A_{22}\end{pmatrix}\ \to\ A^{-1}=\begin{pmatrix}A_{11}^{-1}(I+A_{12}T^{-1}A_{21}A_{11}^{-1}) & -A_{11}^{-1}A_{12}T^{-1}\\ -T^{-1}A_{21}A_{11}^{-1} & T^{-1}\end{pmatrix},$$

where $T=A_{22}-A_{21}A_{11}^{-1}A_{12}$. In our case $A_{12}=I_k$, $A_{22}=0:=0_k$, $T=-A_{21}A_{11}^{-1}\Rightarrow T^{-1}=-A_{11}A_{21}^{-1}$, whence we derive the simple formula for the matrix Ω^{-1}

$$\Omega^{-1}=\begin{pmatrix}0 & A_{21}^{-1}\\ I_k & -A_{11}A_{21}^{-1}\end{pmatrix}=\begin{pmatrix}0 & (\vec{\alpha}^{\top}\vec{\varphi}-I_k)^{-1}\\ I_k & -\displaystyle\int_{-\infty}^{x}\vec{\varphi}^{\top}\vec{\varphi}_x\,dx\,(\vec{\alpha}^{\top}\vec{\varphi}-I_k)^{-1}\end{pmatrix}.$$

Thus $\boldsymbol{q}:=\varphi\Omega^{-1}=(\vec{\alpha},\vec{\boldsymbol{q}})$, where

$$\vec{\boldsymbol{q}}=\left(\vec{\varphi}+\vec{\alpha}\int_{-\infty}^{x}\vec{\varphi}^{\top}\vec{\varphi}_x\,dx\right)(\vec{\alpha}^{\top}\vec{\varphi}-I_k)^{-1}. \tag{19}$$

The matrix $\mathcal{M}=C\hat{\Lambda}-\hat{\Lambda}^{\top}C$ is of the form $\mathcal{M}=\begin{pmatrix}0 & -\Lambda^{\top}\\ -\Lambda & 0\end{pmatrix}$, as $\hat{\Lambda}=\begin{pmatrix}\Lambda & 0\\ 0 & 0\end{pmatrix}$. For the completion of the proof it is sufficient to refer to formulas (15)–(19) and to the corresponding results of Theorem 3 for the mKdV equation (14). ■

The possibility of application of other reductions in $\mathcal{D}$HcmKP hierarchy requires further research.

New Classes of Nonlinear Evolutionary Equations

Lev M. BERKOVICH

Samara State University, 1 Academician Pavlov Str., 443011 Samara, Russia
E-mail: *berk@ssu.samara.ru*

We consider new classes of nonlinear evolutionary equations (NEEs) of the n-th order depending on two arbitrary functions such that the solutions to these equations of traveling wave type satisfy the corresponding nonlinear superposition principles (NSPs). The construction is based on the methods of the factorization and exact linearization of ordinary differential equations (ODEs)

1 Introduction

In the papers [1] and [2] some higher analogs of the nonlinear evolutionary equation of Korteweg–de Vries are considered. Some NEEs of the higher order are represented in handbook [3]. In the present paper we have constructed new types of NEEs of higher order. For their construction the methods of factorization and exact linearization were used (see [4–8]).

In Section 2 the summary of results on the method of a exact linearization is given. In Section 3 the NEEs of n-th order depending on one arbitrary function and reducible to linear evolutionary equations (LEEs) by a nonlinear substitution of dependent variable are constructed. In Section 4 the NEEs of n-th order depending on two arbitrary functions are constructed. Their solutions of traveling wave type satisfying to nonlinear ODEs, linearized by transformation dependent and independent variables. In Section 5 the NEEs of n-th order depending on two arbitrary functions also are are constructed. Their stationary solutions satisfy to the nonlinear ODEs reduced to the semilinear equations.

2 On the method of exact linearization for ordinary differential equations

Lemma 1. *An autonomous second-order ODE*

$$F(y, y', y'') = 0, \qquad ()' = \frac{d}{dx} \tag{1}$$

can be reduced to the linear form

$$z''(s) + 2b_1 z'(s) + b_2 z(s) = 0, \qquad b_1, b_2 = \text{const}, \tag{2}$$

by a nonlinear transformation of the dependent and independent variables

$$y = v(y)z, \qquad ds = ydx \tag{3}$$

if and only if (1) *can be factored into noncommutative nonlinear differential operators as*

$$\left(D - \left(\frac{v^*}{v} + \frac{u^*}{u}\right)y' - r_2 u\right)\left(D - \frac{v^*}{v}y' - r_1 u\right)y = 0, \qquad D = \frac{d}{dx}, \qquad ()^* = \frac{d}{dy} \tag{4}$$

or into commutative operators as

$$\left(\frac{1}{u}D - \frac{v^*}{vu}y' - r_2\right)\left(\frac{1}{u}D - \frac{v^*}{vu}y' - r_1\right)y = 0,$$

where r_1 and r_2 are the roots of the characteristic equation

$$r^2 + 2b_1 r + b_2 = 0. \tag{5}$$

Lemma 2. *Equation* (1) *can be linearized by transformation* (3)*, if and only if it can be represented in the form*

$$y'' + fy'^2 + 2b_1\varphi y' + b_2\varphi \exp\left(-\int f dy\right)\int \varphi \exp\left(\int f dy\right) dy = 0, \tag{6}$$

where $f = f(y)$, $\varphi = \varphi(y)$, that reduces to (2) by the transformation

$$z = \beta \int \varphi \exp\left(\int f dy\right) dy, \qquad ds = \varphi(y)dx, \tag{7}$$

where $\beta = \text{const} \neq 0$ is a normalizing factor.

Lemma 3. *An autonomous n-th order ODE*

$$F\left(y, y', \ldots, y^{(n)}\right) = 0 \tag{8}$$

can be reduced to a linear autonomous form

$$M_n(z) \equiv z^{(n)}(s) + \sum_{k=1}^{n} \binom{n}{k} b_k z^{(n-k)}(s) = 0, \qquad b_k = \text{const}$$

by transformation (3) *if and only if* (8) *can be represented in the form*

$$\prod_{k=n}^{1} \left[D - \left(\frac{1}{y} - \left(\ln \int \varphi^{\frac{n^2-n+2}{2n}} \exp\left(\int f dy\right) dy\right)^* + (k-1)\frac{\varphi^*}{\varphi}\right) y' - r_k\varphi\right] y = 0, \tag{9}$$

where r_k are the roots of the characteristic equation

$$M_n(r) \equiv r^n + \sum_{k=1}^{n} \binom{n}{k} b_k r^{n-k} = 0; \tag{10}$$

the linearizing transformation (2) then has the form

$$z = \beta \int \varphi^{\frac{n^2-n+2}{2n}} \exp\left(\int f dy\right) dy, \qquad ds = \varphi dx, \tag{11}$$

where $\beta = \text{const} \neq 0$ is a normalizing factor.

Note 1. The structure of linearizable equations. Linearizable equations depend on two arbitrary functions and n parameters serving as coefficients of the linear equations. They are algebraic with respect to the derivatives of the dependent variable which they include. The higher-order equations are constructed on the basis of recursive relations. The order of the nonlinear term is determined as the sum of the products of the orders of derivatives by their exponents. Each equation belonging to the class under examination can be represented as an algebraic sum of terms (with coefficients expressed through the dependent variable) each of which consists of nonlinear terms of the same order. The order of the term not depending on the coefficients of the transformed linear equation equals the order of the equation. All the other terms have smaller orders and contain coefficients (parameters) of the linear equation. Then, a linearizable equation can be represented in the form

$$\sum_{k_1+2k_2+\cdots+nk_n=n} \Psi^{12\ldots n}_{k_1 k_2 \ldots k_n} y^{(1)k_1} y^{(2)k_2} \ldots y^{(n)k_n}$$

$$+\sum_{m=1}^{n-1}\binom{n}{m}b_m\varphi^m\left(\sum_{l_1+2l_2+\cdots+(n-m)l_{n-m}=n-m}\Psi^{12\ldots n-m}_{l_1l_2\ldots l_{n-m}}y^{(1)l_1}y^{(2)l_2}\ldots y^{(n-m)l_{n-m}}\right)$$
$$+b_n\exp\left(-\int f dy\right)\int\varphi^{\frac{n^2+n-2}{2n}}\exp\left(\int f dy\right)dy=0, \tag{12}$$

where the coefficients Ψ depend on $f(y)$ and $\varphi(y)$ and

$$\Psi^{12\ldots n}_{00\ldots1}=1,\qquad \Psi^{12\ldots n-m}_{00\ldots1}=1,\qquad \Psi^{12\ldots n-1n}_{10\ldots10}=nf(y).$$

3 Nonlinear evolutionary equations reducible to linear evolutionary equations

Proposition 1. *An NEE*

$$\frac{\partial y}{\partial t}=F\left(y,\frac{\partial y}{\partial x},\ldots,\frac{\partial^n y}{\partial x^n}\right),\qquad y=y(t,x) \tag{13}$$

reduces to a linear evolutionary equation (LEE)

$$\frac{\partial z}{\partial t}=\sum_{k=0}^{n}\binom{n}{k}b_k\frac{\partial^{n-k}z}{\partial x^{n-k}}, \tag{14}$$

by substitution of the form (see (3)*)*

$$y=v(y)z, \tag{15}$$

if and only if (13) *can be factored as*

$$\left(1-\frac{v^*}{v}y\right)\frac{\partial y}{\partial t}=\prod_{k=1}^{n}\left(\frac{\partial}{\partial x}-\frac{v^*}{v}\frac{\partial y}{\partial x}-r_k\right)y, \tag{16}$$

where r_k are the roots of characteristic equation (10)*.*

Theorem 1. *NEE* (13) *reduces to LEE* (14) *by substitution* (15) *if and only if it can be represented in the form*

$$\frac{\exp\left(\int f dy\right)y}{\int\exp(\int f dy)dy}\frac{\partial y}{\partial t}=\prod_{k=1}^{n}\left[\frac{\partial}{\partial x}-\left(\frac{1}{y}-\frac{\exp\left(\int f dy\right)}{\int\exp(\int f dy)dy}\right)\frac{\partial y}{\partial x}-r_k\right]y, \tag{17}$$

linearizing substitution (15) *then has an explicit form*

$$z=\beta\int\exp\left(\int f dy\right)dy,\qquad \beta=\text{const}\neq0. \tag{18}$$

Proof. We apply Lemma 3, equation (16), and the formula

$$1-\frac{v^*}{v}y=\frac{\exp\left(\int f dy\right)y}{\int\exp\left(\int f dy\right)dy}.$$ ■

Equation (13) in form (16) satisfies the nonlinear superposition principle (NSP)

$$z=\int\exp\left(\int f dy\right)dy=\sum_{k=1}^{n}c_kz_k(t,x),$$

where c_k are arbitrary constants and $z_k(t,x)$ are linearly independent partial solutions to LEE (14).

Example 1. The equation[1]

$$y_t = \frac{h}{2}y_{xx} - \frac{1}{2}y_x^2, \qquad h = \text{const} \tag{19}$$

belongs to the class (17) and it is reduced to the LEE

$$z_t = -hz_{xx} \tag{20}$$

by the transformation $z = \exp(-y/h)$. Let $z_1(t,x)$ and $z_2(t,x)$ be its linearly independent solutions. Then the complete integral $z = c_1z_1 + c_2z_2$ of LEE (20), where c_1 and c_2 are arbitrary constants, is a linear superposition principle, and the formula

$$y = -h\ln\left[\exp\left(-\frac{1}{h}y_1 - \frac{\lambda_1}{h}\right) + \exp\left(-\frac{1}{h}y_2 - \frac{\lambda_2}{h}\right)\right]$$

is a NSP for (19), where λ_1 and λ_2 are arbitrary constants, $y_1(x,t)$ and $y_2(x,t)$ are particular solutions, and $y(x,t)$ is a complete integral of equation (19).

Note that equation (19) can be linearized into the equation $z_t = z_{ss}$ by the transformation $z = \exp(-y/h)$, $ds = \sqrt{2/h}dx$.

Note 2. In idempotent analysis, the correspondence principle (in the sense of Maslov) is an NSP (see for example [9]).

Example 2. The equation

$$\begin{aligned} y_t = {} & y^{\text{iv}} + 4fy'y''' + 3fy''^2 + 6(f^2 + f^*)y'^2y'' + (f^3 + 3ff^* + f^{**})y'^4 \\ & + 4b_1(y''' + 3fy'y'' + (f^2 + f^*)y'^3) \\ & + 6b_2(y'' + fy'^2) + 4b_3y' + b_4\exp\left(-\int f dy\right)\int \exp\left(\int f dy\right)dy = 0 \end{aligned}$$

can be reduced by substitution (18) to the corresponding fourth-order LEE.

A nonlinear ODE linearizable by transformation (18) was constructed in [10].

4 Nonlinear evolutionary equations with linearizable right-hand sides

Proposition 2. *NEE* (13) *has a solution of the traveling wave type*

$$y(\tau) = y(x - at) \tag{21}$$

and can be reduced to a linear ODE by the substitution

$$y = v(y)z, \qquad ds = u(y)d\tau, \tag{22}$$

if and only if

$$u^{n-1}\left(1 - \frac{v^*}{v}y\right)\frac{\partial y}{\partial t} = \prod_{k=n}^{1}\left[\frac{\partial}{\partial x} - \left(\frac{v^*}{v} + (k-1)\frac{u^*}{u}\right)\frac{\partial u}{\partial x} - r_ku\right]y, \tag{23}$$

where r_k are the roots of characteristic equation (10).

[1]This example was adduced in works of V.P. Maslov and his coauthors.

Proof. Sufficiency. First, note that the right-hand side of equation (23) generalizes formula (4). We seek a traveling wave type solution (21) for (23):

$$-au^{n-1}\left(1-\frac{v^*}{v}y\right)y_\tau=\prod_{k=n}^{1}\left[D_\tau-\left(\frac{v^*}{v}+(k-1)\frac{u^*}{u}\right)y_\tau-r_ku\right]y,\qquad D_\tau=\frac{d}{d\tau}.\tag{24}$$

Let us rewrite the left-hand side of (24) in the form

$$-au^{n-1}\left(D_\tau-\frac{v^*}{v}y_\tau\right)y$$

and apply substitution (22). We obtain, successively,

$$-au^{n-1}vD_\tau z=v\prod_{k=n}^{1}\left[D_\tau-(k-1)\frac{u^*}{u}y_\tau-r_ku\right]z,$$

$$-au^{n-1}vuD_sz=vu^n\prod_{k=n}^{1}(D_s-r_k)z,\qquad D_s=uD_\tau,\tag{25}$$

$$\sum_{k=0}^{n}\binom{n}{k}b_kz^{(n-k)}(s)+az'(s)=0,\qquad b_0=1,\qquad ()'=\frac{d}{ds}.\tag{26}$$

The **necessity** of conditions (23) is proved on the basis of equation (25). ■

Theorem 2. *NEE* (13) *with condition* (23) *has a traveling wave type solution* (21) *if and only if* (23) *can be represented in the form*

$$\frac{\varphi^{\frac{3n^2-3n+2}{2n}}\exp\left(\int f dy\right)y}{\int\varphi^{\frac{n^2-n+2}{2n}}\exp\left(\int f dy\right)dy}\frac{\partial y}{\partial t}$$
$$=\prod_{k=n}^{1}\left[\frac{\partial}{\partial x}-\left(\frac{1}{y}-\frac{\varphi^{\frac{n^2-n+2}{2n}}\exp\left(\int f dy\right)}{\int\varphi^{\frac{n^2-n+2}{2n}}\exp\left(\int f dy\right)dy}+(k-1)\frac{\varphi^*}{\varphi}\right)\frac{\partial y}{\partial x}-r_k\varphi\right]y,\tag{27}$$

where r_k *with* $k=1,2,\dots,n$ *are the roots of characteristic equation* (10)*, or in lexicographic form*

$$\varphi^{n-1}y_t=\sum_{k_1+2k_2+\cdots+nk_n=n}\Psi^{12\dots n}_{k_1k_2\dots k_n}y^{(1)k_1}y^{(2)k_2}\dots y^{(n)k_n}$$
$$+\sum_{m=1}^{n-1}\binom{n}{m}b_m\varphi^m\left(\sum_{l_1+2l_2+\cdots+(n-m)l_{n-m}=n-m}\Psi^{12\dots n-m}_{l_1l_2\dots l_{n-m}}y^{(1)l_1}y^{(2)l_2}\dots y^{(n-m)l_{n-m}}\right)$$
$$+b_n\exp\left(-\int f dy\right)\int\varphi^{\frac{n^2+n-2}{2n}}\exp\left(\int f dy\right)dy=0,\tag{28}$$

where the coefficients Ψ *depend on* $f(y)$ *and* $\varphi(y)$ *and*

$$\Psi^{12\dots n}_{00\dots1}=1,\qquad \Psi^{12\dots n-m}_{00\dots1}=1,\qquad \Psi^{12\dots n-1n}_{10\dots10}=nf(y).$$

Then substitution (21) *which gives linear ODE* (25) *has the form*

$$z=\beta\int\varphi^{\frac{n^2-n+2}{2n}}\exp\left(\int f dy\right)dy,\qquad ds=\varphi d\tau.$$

Proof. We apply Lemma 3, Proposition 2, formulas (9), (11), (12), (14), and the formula

$$1-\frac{v^*}{v}y=\frac{\varphi^{\frac{n^2-3n+2}{2n}}\exp\left(\int f dy\right)y}{\int\varphi^{\frac{n^2-n+2}{2n}}\exp\left(\int f dy\right)dy}.$$

■

Theorem 3 (see [5]). *Let $z_1(s), z_2(s), \dots, z_n(s)$ be linearly independent particular solutions to equation* (25)*. Then the general integral of* (25) *is*

$$z=c_1z_1(s)+c_2z_2(s)+\cdots+c_nz_n(s),$$

where $c_1, c_2, \dots, c_n$ are arbitrary constants, and this formula is an LSP. The NSP for (27), (28) *is obtained by the formulas*

$$z=\varphi^{\frac{n^2-n+2}{2n}}\exp\left(\int f dy\right)=\sum_{k=1}^{n}c_kz_k(s),\qquad ds=\varphi d\tau,\qquad \tau=x-at.$$

The general form of a second-order NEE belonging to class (28) *(see also* (5) *and* (6)*) is*

$$\varphi y_t=y_{xx}+fy_x^2+2b_1\varphi y_x+b_2\varphi\exp\left(-\int f dy\right)\int\varphi\exp\left(\int f dy\right)dy.$$

Next, we have

$$-a\varphi y_\tau=y_{\tau\tau}+fy_\tau^2+2b_1\varphi y_\tau+b_2\varphi\exp\left(-\int f dy\right)\int\varphi\exp\left(\int f dy\right)dy.$$

The substitution (see formula (7)) $z=\beta\int\varphi\exp\left(\int f dy\right)dy$, $ds=\varphi d\tau$ yields a linear equation

$$z''(s)+2b_1z'(s)+b_2z(s)+az'(s)=0.$$

Example 3. Consider the equation

$$yy_t=y_{xx}+3yy_x+y^3. \tag{29}$$

Seeking a solution of type (21) for equation (29) leads to the ODE $-ayy_\tau=y_{\tau\tau}+3yy_\tau+y^3$. Using the substitution $y^2=z$, $ds=yd\tau$, we obtain a linear equation

$$z''(s)+3z'(s)+2z(s)+az'(s)=0.$$

The general form of an NEE of order $n=3$ belonging to a class (28), is

$$\begin{aligned}\varphi^2y_t=y_{xxx}+3fy_xy_{xx}+\left(\frac{1}{3}\frac{\varphi_{yy}}{\varphi}-\frac{5}{9}\frac{\varphi_y^2}{\varphi^2}-\frac{1}{3}f\frac{\varphi_y}{\varphi}+f^2+f_y\right)y_x^3\\+3b_1\varphi\left[y_{xx}+\left(f+\frac{1}{3}\frac{\varphi_y}{\varphi}\right)y_x^2\right]+3b_2\varphi^2y_x\\+b_3\varphi^{5/3}\exp\left(-\int f dy\right)\int\varphi^{4/3}\exp\left(\int f dy\right)dy.\end{aligned} \tag{30}$$

Example 4. Consider the Harry–Dym equation

$$y_t=y^3y_{xxx}. \tag{31}$$

It belongs to class (30), namely

$$\varphi^2 y_t = y_{xxx} + \left(\frac{1}{3}\frac{\varphi_{yy}}{\varphi} - \frac{5}{9}\frac{\varphi_y^2}{\varphi^2}\right) y_x^3 + b_3\varphi^{3/5}\int \varphi^{4/5} dy$$

with $f = 0$, $b_3 = 0$, $\varphi = y^{-3/2}$. It admits the representation

$$y^{-3} y_t = \left(\partial_x + \frac{y_x}{y}\right)\left(\partial_x - \frac{1}{2}\frac{y_x}{y}\right) y_x.$$

The ordinary differential equation corresponding to a solution of (31) of type (21) has the form

$$y'''(\tau) + a y^{-3} y'(\tau) = 0. \tag{32}$$

Equation (32) is reduced to the linear form $z'''(s) + az'(s) = 0$ by the substitution $z = 1/y$, $ds = y^{-3/2} d\tau$.

5 Nonlinear evolutionary equations with factorable right-hand sides

The new classes of the nonlinear evolutionary equations (NEE) of n-th order, depending on two arbitrary functions and $n-1$ parameters, are constructed (see also [11]):

$$\frac{\partial y}{\partial t} = \frac{\partial}{\partial x}\left[\frac{v}{v - v^* y}\prod_{k=n-1}^{1}\left(\frac{\partial}{\partial x} - \left(\frac{v^*}{v} + (k-1)\frac{u^*}{u}\right)\frac{\partial y}{\partial x} - r_k u\right)\right] y, \tag{33}$$

where $r_k = \text{const}$, $k = 1, \ldots, n-1$, $v = v(y)$, $u = u(y)$, $()^* = d/dy$.

Besides solutions such as a traveling wave, stationary solutions of the equation (33) are also of interest. The corresponding ODE have the form

$$\prod_{k=n-1}^{1}\left[\frac{\partial}{\partial x} - \left(\frac{v^*}{v} + (k-1)\frac{u^*}{u}\right)\frac{dy}{dx} - r_k u\right] y = C\left(1 - \frac{v^*}{v} y\right), \qquad D = \frac{d}{dx}. \tag{34}$$

By substitution $y = v(y)z$, $ds = u(y)dx$ the equation (34) is reduced to a semilinear equation

$$\prod_{k=n-1}^{1}(D_s - r_k) z = C\left(1 - \frac{v^*}{v} y\right) v^{-1} u^{1-n}, \tag{35}$$

where right-hand side is a function of z.

Example 5. The Korteweg–de Vries equation (KdV)

$$y_t + y_{xxx} - 6 y y_x = 0$$

belongs to the class (33) and admits a representation of the form

$$y_t + \partial_x(y_{xx} - 3y^2) = 0$$

and also a factorization

$$y_t + \frac{2}{3}\partial_x\left(\partial_x - r_2 y^{1/2}\right)\left(\partial_x + \frac{1}{2}\frac{y_x}{y} - r_1 y^{1/2}\right) y = 0,$$
$$r_{1,2} = \mp\frac{3}{\sqrt{2}}, \qquad u = y^{1/2}, \qquad v = y^{-1/2}.$$

The semilinear equation corresponding to (35) is the equation

$$z''(s) - \frac{9}{2}z = Cz^{-1/3}.$$

Example 6. Consider modified KdV-equation (MKdV)

$$y_t + y_{xxx} - 6y^2y_x = 0.$$

It admits a factorization $y_t + \partial_x(y_{xx} - 2y^3) = 0$, and the following

$$y_t + \frac{1}{2}\partial_x(\partial_x - 2y)\left(\partial_x + \frac{y_x}{y} + 2y\right)y = 0,$$

here $u = y$, $v = y^{-1}$, $r_{1,2} = \pm 2$.

Example 7. Generalized MKdV-equation

$$y_t + y_{xxx} - ay^k y_x = 0$$

admits first a representation

$$y_t + \partial_x\left(y_{xx} + \frac{a}{k+1}y^{k+1}\right) = 0,$$

and then a factorization

$$y_t + \frac{2}{k+2}\partial_x\left(\partial_x - r_2y^{k/2}\right)\left(\partial_x + \frac{k}{2}\frac{y_x}{y} - r_1y^{k/2}\right)y = 0,$$

where $u = y^{k/2}$, $v = y^{-k/2}$, $r_{1,2} = \pm i\sqrt{\frac{a(k+2)}{2(k+1)}}$.

Corresponding semilinear equation has the form

$$\ddot{z} + \frac{a(k+2)}{2(k+1)}z = Cz^{-\frac{k}{k+2}}.$$

Liouville integrable separable systems with quadratic in momenta first integrals are considered. Particular attention is paid to the systems generated by so-called special conformal Killing tensors, i.e. Benenti systems. Then infinitely many new classes of separable systems are constructed by appropriate deformations of Benenti class systems.

1 Introduction

The separation of variables for solving by quadratures of the Hamilton–Jacobi (HJ) equations of related Liouville integrable dynamic systems with quadratic in momenta first integrals has a long history as a part of analytical mechanics. There are some milestones of that theory. First, in 1891 Stäckel initiated a program of classification of separable systems presenting conditions for separability of the HJ equations in orthogonal coordinates [1–3]. Then, in 1904 Levi-Civita found a test for the separability of a Hamiltonian dynamics in a given system of canonical coordinates [4]. The next was Eisenhart [5–7], who in 1934 inserted a separability theory in the context of Riemannian geometry, making it coordinate free and introducing the crucial objects of the theory, i.e. Killing tensors. This approach was then developed by Woodhouse [8], Klanins [9, 10] and others. Finally, in 1992, Benenti [11–13] constructed a particular, but very important subclass of separable systems, based on the so called special conformal Killing tensors.

The first constructive theory of separated coordinates for dynamical systems was made by Sklyanin [15]. He adopted the method of soliton theory, i.e. the Lax representation, to systematic derivation of separated coordinates. In that approach involutive functions appear as coefficients of characteristic equation (spectral curve) of Lax matrix. The method was successfully aplied to separation of variables for many integrable systems [15–20].

Recently, a modern geometric theory of separability on bi-Poisson manifolds was constructed [21–26], related to the so-called Gel'fand–Zakharevich (GZ) bi-Hamiltonian systems [27, 28]. Obviously, it contains as a special case Liouville integrable systems with all constants of motion being quadratic in momenta functions. Indeed, Ibort et.al. [29] proved that the Benenti class of systems can be lifted to the GZ bi-Hamiltonian form.

In the following paper we construct in a systematic way all Liouville integrable systems on Riemannian spaces, which are of the GZ type, including as a special case the Benenti class of systems. What is important, infinitely many classes of separable systems are constructed from appropriate deformations of the Benenti class of systems. In that sense we demonstrate the crucial role of this particular class of systems in the separability theory of dynamic systems with quadratic in momenta first integrals.

2 Separable dynamics on Riemannian spaces

Let (Q, g) be a Riemann (pseudo-Riemann) manifold with covariant metric tensor g and local coordinates $q^1, \ldots, q^n$. Moreover, let $G := g^{-1}$ be a contravariant metric tensor satisfying

$\sum\limits_{j=1}^{n} g_{ij}G^{jk} = \delta_i^k$. The equations

$$q_{tt}^i + \Gamma_{jk}^i q_t^j q_t^k = G^{ik}\partial_k V(q), \quad i = 1, \ldots, n, \qquad q_t \equiv \frac{dq}{dt} \tag{1}$$

describe the motion of a particle in the Riemannian space with the metric g, where Γ_{jk}^i are the Levi-Civita connection components. Equations (1) can be obtained by varying the Lagrangian

$$\mathcal{L}(q, q_t) = \frac{1}{2}\sum_{i,j} g_{ij} q_t^i q_t^j - V(q) \tag{2}$$

and are called Euler–Lagrange equations. Obviously, for $G = I$ equations (1) reduce to Newton equations of motion.

One can pass in a standard way to the Hamiltonian description of dynamics, where the Hamiltonian function takes the form

$$H(q,p) = \sum_{i=1}^{n} q_t^i \frac{\partial \mathcal{L}}{\partial q_t^i} - \mathcal{L} = \frac{1}{2}\sum_{i,j=1}^{n} G^{ij} p_i p_j + V(q), \qquad p_i := \frac{\partial \mathcal{L}}{\partial q_t^i} = \sum_j g_{ij} q_t^j$$

and equations of motion are

$$\begin{pmatrix} q \\ p \end{pmatrix}_t = \theta_0 dH = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix} \begin{pmatrix} \frac{\partial H}{\partial q} \\ \frac{\partial H}{\partial p} \end{pmatrix} = X_H \iff q_t^i = \frac{\partial H}{\partial p_i}, \qquad p_{it} = -\frac{\partial H}{\partial q^i}.$$

X_H denotes the Hamiltonian vector field with respect to a canonical Poisson tensor θ_0 and the whole dynamics takes place on the phase space $M = T^*Q$ in local coordinates $(q^1, \ldots, q^n, p_1, \ldots, p_n)$.

Of special importance is the geodesic motion $V(q) \equiv 0$, with Euler–Lagrange equations and Hamiltonian representation in the form

$$q_{tt}^i + \Gamma_{jk}^i q_t^j q_t^k = 0, \quad i = 1, \ldots, n \iff \begin{pmatrix} q \\ p \end{pmatrix}_t = \theta_0 dE = X_E, \quad E = \frac{1}{2}\sum_{i,j=1}^{n} G^{ij} p_i p_j.$$

Functionally independent Hamiltonian functions H_i, $i = 1, \ldots, n$ are said to be separable in the canonical coordinates (λ, μ) if there are n relations, called the separation conditions (Sklyanin [15]), of the form

$$\varphi_i(\lambda^i, \mu_i; H_1, \ldots, H_n) = 0, \quad i = 1, \ldots, n, \qquad \det\left[\frac{\partial \varphi_i}{\partial H_j}\right] \neq 0, \tag{3}$$

which guarantee the solvability of the appropriate Hamilton–Jacobi equations and involutivity of H_i. A special case, when all separation relations (3) are affine in H_i, is given by the set of equations

$$\sum_{k=1}^{n} \phi_i^k(\lambda_i, \mu_i) H_k = \psi_i(\lambda_i, \mu_i), \quad i = 1, \ldots, n, \tag{4}$$

where ϕ and ψ are arbitrary smooth functions of their arguments, is called the *Stäckel separation conditions* and the related dynamic systems are called Stäckel separable.

We are going to present a subclass of one-particle dynamics, containing Liouville integrable and separable systems with n quadratic in momenta constants of motion. Stäckel [1–3] was the first who gave the characterization of equations of motion integrable by separation of variables.

He proved that if in a system of orthogonal coordinates (λ,μ) there exists a non-singular matrix $\varphi=(\varphi_k^l(\lambda_k))$, called a *Stäckel matrix* such that the Hamiltonians H_r are of the form

$$H_r=\frac{1}{2}\sum_{i=1}^{n}(\varphi^{-1})_r^i(\mu_i^2+\sigma_i(\lambda_i)), \tag{5}$$

then H_r are functionally independent, pairwise commute with respect to the canonical Poisson bracket and the Hamilton–Jacobi equation associated to H_1 is separable. Indeed, for quadratic in momenta constants of motion, the Stäckel separation conditions (4) take the general form

$$\sum_{k=1}^{n}\phi_i^k(\lambda^i)H_k=\frac{1}{2}f_i(\lambda^i)\mu_i^2+\gamma_i(\lambda^i),\qquad i=1,\dots,n, \tag{6}$$

where f_i, γ_i, ϕ_i^k are arbitrary smooth functions of its argument and the normalization $\phi_i^n=1$, $i=1,\dots,n$ is assumed. To get the explicit form of $H_k=H_k(\lambda,\mu)$ one has to solve the system of linear equations (6). The results are the following

$$\varphi=\begin{pmatrix}\frac{\phi_1^1(\lambda^1)}{f_1(\lambda^1)} & \frac{\phi_1^2(\lambda^1)}{f_1(\lambda^1)} & \dots & \frac{\phi_1^{n-1}(\lambda^1)}{f_1(\lambda^1)} & \frac{1}{f_1(\lambda^1)}\\ \vdots & \vdots & \dots & \vdots & \vdots\\ \frac{\phi_n^1(\lambda^n)}{f_n(\lambda^n)} & \frac{\phi_n^2(\lambda^n)}{f_n(\lambda^n)} & \dots & \frac{\phi_n^{n-1}(\lambda^n)}{f_n(\lambda^n)} & \frac{1}{f_n(\lambda^n)}\end{pmatrix},\qquad \sigma_i(\lambda_i)=\gamma_i(\lambda^i)/f_i(\lambda^i).$$

Eisenhart considered Stäckel separable systems in the frame of one-particle dynamics on Riemannian (pseudo-Riemannian) space (Q,g). He gave a coordinate-free representation for Stäckel geodesic motion introducing a special family of *Killing tensors* [5–7]. As known, a $(1,1)$-type tensor $K=(K_j^i)$ (or a $(2,0)$-type tensor $KG=A=(A^{ij})$) is called a Killing tensor with respect to g if

$$\Big\{\sum A^{ij}p_ip_j,\sum G^{ij}p_ip_j\Big\}_{\theta_0}=0,$$

where $\{\cdot,\cdot\}_{\theta_0}$ means a canonical Poisson bracket. He proved [5–7] that the geodesic Hamiltonians can be transformed into the Stäckel form (5) if the contravariant metric tensor $G=g^{-1}$ has $(n-1)$ commuting independent contravariant Killing tensors A_r of a second order such that

$$E_r=\frac{1}{2}\sum_{i,j}A_r^{ij}p_ip_j,$$

admitting a common system of closed eigenforms α_i

$$(A_r^*-v_r^iG)\alpha_i=0,\qquad d\alpha_i=0,\qquad i=1,\dots,n,$$

where v_r^i are eigenvalues of $(1,1)$ Killing tensor $K_r=A_rg$ $(K_r^*=gA_r^*)$.

For n degrees of freedom, let us consider n Stäckel Hamiltonian functions in separated coordinates in the following form

$$H_r=\frac{1}{2}\sum_{i=1}^{n}v_r^iG^{ii}\mu_i^2+V_r(\lambda)=\frac{1}{2}\mu^TK_rG\mu+V_r(\lambda),\quad r=1,\dots,n, \tag{7}$$

where $\mu=(\mu_1,\dots,\mu_n)^T$ and $V_r(\lambda)$ are appropriate potentials separable in (λ,μ) coordinates. For the integrable system (7) calculated from (6)

$$G^{ii}=(-1)^{i+1}\frac{f_i(\lambda^i)\det W^{i1}}{\det W},\qquad v_r^i=(-1)^{r+1}\frac{\det W^{ir}}{\det W^{i1}},\qquad V_r=\sum_{i=1}^{n}(-1)^{i+r}\gamma_i(\lambda^i)\frac{\det W^{ir}}{\det W},$$

where

$$W = \begin{pmatrix} \phi_1^1(\lambda^1) & \phi_1^2(\lambda^1) & \cdots & \phi_1^{n-1}(\lambda^1) & 1 \\ \vdots & \vdots & \cdots & \vdots & \vdots \\ \phi_n^1(\lambda^n) & \phi_n^2(\lambda^n) & \cdots & \phi_n^{n-1}(\lambda^n) & 1 \end{pmatrix}$$

and W^{ik} is the $(n-1)\times(n-1)$ matrix obtained from W after we cancel its ith row and kth column.

In our further considerations we restrict to the so-called GZ case, when $\phi_i^k(\lambda_i)$ are monomials, $f_i = f$ and $\gamma_i = \gamma$. Then, the Stäckel separation conditions are n copies of a so-called separation curve

$$H_1\xi^{m_1} + \cdots + H_n\xi^{m_n} = \frac{1}{2}f(\xi)\mu^2 + \gamma(\xi), \qquad m_n = 0 < m_{n-1} < \cdots < m_1 \in \mathbb{N}, \tag{8}$$

with $(\xi,\mu) = (\lambda^i, \mu_i)$, $i = 1,\dots,n$.

In (λ,μ) coordinates n related Hamilton–Jacobi (HJ) equations

$$H_r\left(\lambda, \frac{\partial W}{\partial \lambda}\right) = a_r, \qquad r = 1,\dots,n,$$

for a generation function $W(\lambda,a) = \sum\limits_{i=1}^{n} W_i(\lambda_i,a)$, decouple into n ordinary differential equations

$$\frac{1}{2}f(\lambda^i)\left(\frac{dW_i}{d\lambda^i}\right)^2 + \gamma(\lambda^i) = a_1(\lambda^i)^{m_1} + a_2(\lambda^i)^{m_2} + \cdots + a_n \equiv a(\lambda^i)$$

and hence, the implicit solution of dynamical system with Hamiltonian function H_r is given by

$$\sum_{k=1}^{n}\int^{\lambda^k} \frac{\xi^{m_i}}{\sqrt{\psi(\xi)}}d\xi = t_r\delta_{ri} + \text{const}_i, \qquad i = 1,\dots,n,$$

where $2f(\xi)[a(\xi) - \gamma(\xi)] \equiv \psi(\xi)$, called the *inverse Jacobi problem*.

In this context, a question about classification and construction in natural coordinates of all separable systems on Riemannian spaces, with n quadratic in momenta constants of motion, arises. The classification can be made with respect to the admissible forms of Stäckel separability conditions. The right hand side of the conditions (8) is always the same for the class of systems considered

$$\text{r.h.s.} = \frac{1}{2}f(\lambda^i)\mu_i^2 + \gamma(\lambda^i) = \psi(\lambda^i,\mu_i), \tag{9}$$

so different classes of separable systems are described by different forms of the l.h.s. of Stäckel conditions, while systems from the same class are described by different f and γ in (9).

3 Separable systems in natural coordinates

Among all Stäckel systems a particularly important subclass consists of these considered by Benenti [11–13] and constructed with the help of the so-called *conformal Killing tensor*. Let $L = (L_j^i)$ be a second order mixed type tensor on Q and let $\overline{L} : M \to \mathbb{R}$ be a function on M defined as $\overline{L} = \frac{1}{2}\sum\limits_{i,j=1}^{n}(LG)^{ij}p_ip_j$. If

$$\{\overline{L}, E\}_{\theta_0} = \kappa E, \qquad \text{where} \quad \kappa = \{\varepsilon, E\}_{\theta_0}, \quad \varepsilon = \text{Tr}\,(L),$$

then L is called a conformal Killing tensor with the associated potential $\varepsilon = \mathrm{Tr}\,(L)$. If we assume additionally that L has simple eigenvalues and its Nijenhuis torsion vanishes, then L is called a special conformal Killing tensor [14].

For the Riemannian space (Q, g, L), geodesic flow has n constants of motion of the form

$$E_r = \frac{1}{2}\sum_{i,j=1}^{n} A_r^{ij} p_i p_j = \frac{1}{2}\sum_{i,j=1}^{n} (K_r G)^{ij} p_i p_j, \qquad r = 1, \ldots, n, \tag{10}$$

where A_r and K_r are Killing tensors of type $(2,0)$ and $(1,1)$, respectively. Moreover, as was shown by Benenti [11, 12], all the Killing tensors K_r with a common set of eigenvectors, are constructed from L by

$$K_{r+1} = \sum_{k=0}^{r} \rho_k L^{r-k},$$

where ρ_r are coefficients of the characteristic polynomial of L

$$\det(\xi I - L) = \xi^n + \rho_1 \xi^{n-1} + \cdots + \rho_n, \qquad \rho_0 = 1, \tag{11}$$

or equivalently by the following 'cofactor' formula [30–32]

$$\mathrm{cof}\,(\xi I - L) = \sum_{i=0}^{n-1} K_{n-i} \xi^i,$$

where $\mathrm{cof}\,(A)$ stands for the matrix of cofactors, so that $\mathrm{cof}\,(A)A = (\det A) I$. So, for a given metric tensor g, the existence of a special conformal Killing tensor L is a sufficient condition for the geodesic flow on Q to be a Liouville integrable Hamiltonian system with all constants of motion quadratic in momenta. Moreover, the basic separable potentials $V_r^{(m)}$ are given by the following recursion relation [30–32]

$$V_r^{(m+1)} = \rho_r V_1^{(m)} - V_{r+1}^{(m)}, \tag{12}$$

where the first nontrivial potentials are $V_r^{(0)} = -\rho_r$.

It turns out that we can (generically) associate with the tensor L a coordinate system on Q in which the geodesic flows associated with all the functions E_r separate. Namely, let $(\lambda^1(q), \ldots, \lambda^n(q))$ be n distinct, functionally independent eigenvalues of L, i.e. solutions of the characteristic equation $\det(\xi I - L) = 0$. Solving these relations with respect to q we get the transformation $\lambda \to q: \ q_i = \alpha_i(\lambda)$. The remaining part of the transformation to the separation coordinates can be reconstructed from the generating function $W(p, \lambda) = \sum\limits_i p_i \alpha_i(\lambda)$. In the (λ, μ) coordinates the Stäckel separation conditions (8) for Benenti Hamiltonian functions $H_r = E_r + V_r^{(j)}$ are given by the separation curve of the form

$$H_1 \xi^{n-1} + H_2 \xi^{n-2} + \cdots + H_n = \frac{1}{2} f(\xi)\mu^2 + \xi^{n+j}, \qquad j = 0, 1, 2, \ldots. \tag{13}$$

It is important to notice that all Liouville integrable systems of classical mechanics, with quadratic in momenta first integrals, that was separated in XIX and XX centuries, belong to the Benenti class. The reason is that only the Benenti class contains dynamic systems on flat and constant curvature Riemannian spaces. Another important feature of Benenti systems is that all of them can be lifted to one Casimir bi-Hamiltonian form [29].

Now we present the way to construct all remaining classes of separable systems by an appropriate deformations of the Benenti class. Let us start from the separability condition (8) for n Hamiltonian functions in the following form

$$\widetilde{H}_1\xi^{(n+k)-1} + \widetilde{H}_2\xi^{(n+k)-2} + \cdots + \widetilde{H}_{n+k} = \frac{1}{2}f(\xi)\mu^2 + \xi^{n+j}, \qquad k \in \mathbb{N}, \qquad j \geq k, \tag{14}$$

where $\widetilde{H}_{n_1} = \widetilde{H}_{n_2} = \cdots = \widetilde{H}_{n_k} = 0$, $1 < n_1 < \cdots < n_k < n+k$, and the separability condition for Benenti systems with the same separation coordinates (λ, μ)

$$H_1\xi^{n-1} + H_2\xi^{n-2} + \cdots + H_n = \frac{1}{2}f(\xi)\mu^2 + \xi^{n+j}. \tag{15}$$

Theorem 1. *Deformation of the Benenti system with separation curve* (15) *to the new system with separation curve* (14) *is given by a following determinant form*

$$\widetilde{H}_r = \begin{vmatrix} H_{r-k} & \rho_{r-1} & \cdots & \rho_{r-k} \\ H_{n_1-k} & \rho_{n_1-1} & \cdots & \rho_{n_1-k} \\ \cdots & \cdots & \cdots & \cdots \\ H_{n_k-k} & \rho_{n_k-1} & \cdots & \rho_{n_k-k} \end{vmatrix} \Bigg/ \begin{vmatrix} \rho_{n_1-1} & \cdots & \rho_{n_1-k} \\ \cdots & \cdots & \cdots \\ \rho_{n_k-1} & \cdots & \rho_{n_k-k} \end{vmatrix}, \tag{16}$$

where ρ_i, $i = 0, \ldots, n$ are coefficients of the characteristic polynomial of the conformal Killing tensor L (11) *related to the Benenti system.*

The formula (16) applies separately to the geodesic and the potential parts. The geodesic part $\widetilde{E}_r$ can be presented in the following form

$$\widetilde{E}_r = \frac{1}{2}p^T\widetilde{K}_r\widetilde{G}p, \qquad r = 1, \ldots, n+k, \tag{17}$$

where metric tensor $\widetilde{G}$ and Killing tensors $\widetilde{K}_r$ are

$$\widetilde{G} = (-1)^k\varphi^{-1}D_0G, \qquad \widetilde{K}_r = K_r - K_{r-1}D_1D_0^{-1} + \cdots + (-1)^kK_{r-k}D_kD_0^{-1},$$

$$\varphi = \begin{vmatrix} \rho_{n_1-1} & \cdots & \rho_{n_1-k} \\ \cdots & \cdots & \cdots \\ \rho_{n_k-1} & \cdots & \rho_{n_k-k} \end{vmatrix}, \qquad D_0 = \begin{vmatrix} K_{n_1-1} & \cdots & K_{n_1-k} \\ \cdots & \cdots & \cdots \\ K_{n_k-1} & \cdots & K_{n_k-k} \end{vmatrix},$$

$$D_i = \begin{vmatrix} K_{n_1} & \cdots & K_{n_1-i+1} & K_{n_1-i-1} & \cdots & K_{n_1-k+1} \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ K_{n_k} & \cdots & K_{n_k-i+1} & K_{n_k-i-1} & \cdots & K_{n_k-k+1} \end{vmatrix}, \qquad i = 1, \ldots, k$$

and K_m in determinant calculations are treated as symbols, not as matrices. The proof of the theorem as well as other details can be found in [32].

Systems constructed in such way although obtained through the deformation procedure on the level of Hamiltonian functions, are far from being trivial generalizations of Benenti systems. There is no obvious relations between solutions of a given Benenti system and all its deformations. In each case we have a different inverse Jacobi problem to solve. Notice that the common feature of appropriate deformed systems is the same set of separated coordinates determined by the related Benenti system. Moreover, all of them can be lifted to a multi-Casimir bi-Hamiltonian form [32].

4 Example

Consider the case $n = 2$. Let Q be a two dimensional flat space parametrized by canonical coordinates $q = (q^1, q^2)$ with the contravariant metric tensor G and related special conformal Killing tensor L of the form

$$G = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad L = \begin{pmatrix} q^1 & \frac{1}{2}q^2 \\ \frac{1}{2}q^2 & 0 \end{pmatrix} \implies K_2 = \begin{pmatrix} 0 & \frac{1}{2}q^2 \\ \frac{1}{2}q^2 & -q^1 \end{pmatrix}.$$

Two geodesic Hamiltonians E_1 and E_2, according to (10) are

$$E_1 = \frac{1}{2}p_1^2 + \frac{1}{2}p_2^2, \qquad E_2 = \frac{1}{2}q^2 p_1 p_2 - \frac{1}{2}q^1 p_2^2.$$

Let us choose the potential $V^{(2)}$. As $\rho_1 = -q^1$ and $\rho_2 = -\frac{1}{4}(q^2)^2$ hence

$$V_1^{(2)} = (q^1)^3 + \frac{1}{2}q^1(q^2)^2, \qquad V_2^{(2)} = \frac{1}{16}(q^2)^4 + \frac{1}{4}(q^1)^2(q^2)^2.$$

It is one of the integrable cases of the Henon–Heiles system with Hamiltonian function $H_1 = E_1 + V_1^{(3)}$, second constant of motion $H_2 = E_2 + V_2^{(3)}$ and Newton equations

$$(q^1)_{tt} = -3(q^1)^2 - \frac{1}{2}(q^2)^2, \qquad (q^2)_{tt} = -q^1 q^2.$$

The transformation to separated coordinates (λ, μ) takes the form

$$q^1 = \lambda^1 + \lambda^2, \qquad q^2 = 2\sqrt{-\lambda^1\lambda^2},$$
$$p_1 = \frac{\lambda^1\mu_1}{\lambda^1 - \lambda^2} + \frac{\lambda^2\mu_2}{\lambda^2 - \lambda^1}, \qquad p_2 = \sqrt{-\lambda^1\lambda^2}\left(\frac{\mu_1}{\lambda^1 - \lambda^2} + \frac{\mu_2}{\lambda^2 - \lambda^1}\right),$$

and the separation curve is

$$H_1\xi + H_2 = \frac{1}{2}\xi\mu^2 + \xi^4.$$

Now, let us consider the simplest deformation given by $k = 1$, $n_1 = 2$. Then,

$$\widetilde{G} = -\frac{1}{\rho_1}G = \begin{pmatrix} \frac{1}{q^1} & 0 \\ 0 & \frac{1}{q^1} \end{pmatrix}, \quad \widetilde{K}_2 = 0, \quad \widetilde{K}_3 = -K_2^2 = \begin{pmatrix} -\frac{1}{4}(q^2)^2 & \frac{1}{2}q^1q^2 \\ \frac{1}{2}q^1q^2 & -\frac{1}{4}(q^2)^2 - (q^1)^2 \end{pmatrix},$$
$$\widetilde{V}_1 = -\frac{1}{\rho_1}V_1, \quad \widetilde{V}_2 = 0, \quad \widetilde{V}_3 = V_2 - \frac{\rho_2}{\rho_1}V_1,$$

hence

$$\widetilde{H}_1 = \frac{1}{2}\frac{1}{q^1}p_1^2 + \frac{1}{2}\frac{1}{q^1}p_2^2 + (q^1)^2 + \frac{1}{2}(q^2)^2,$$
$$\widetilde{H}_3 = -\frac{1}{8}\frac{q_2^2}{q^1}p_1^2 + \frac{1}{2}q^2p_1p_2 - \frac{1}{8}\frac{q_2^2}{q^1}p_2^2 - \frac{1}{16}(q^2)^4.$$

$\widetilde{H}_1$ and $\widetilde{H}_2$ are in involution and are separated in the same coordinates (λ, μ) as the Henon–Heiles system. The appropriate separation curve takes the form

$$\widetilde{H}_1\xi^2 + \widetilde{H}_3 = \frac{1}{2}\xi\mu^2 + \xi^4.$$

Asymptotic Irrelevance of the KdV Hierarchy

Luis J. BOYA

Departamento de Física Teórica, Universidad de Zaragoza, E-50009 Zaragoza, Spain
E-mail: *luisjo@unizar.es*

All the equations of the KdV hierarchy share many common features, like single and multiple soliton solutions, singular algebraic potentials, etc.; in particular the phase shifts for soliton-soliton scattering are all the same in the chain KdV_1, KdV_2, etc., depending only on the momenta. We exhibit the reason for this behaviour: as these equations are originated as isopectral deformations of the Schrödinger equation in one dimension, the above features are really properties of the Schrödinger operator, and the different KdV equations just prescribe different "speeds", given by the dispersion law, for reaching the asymptotic regime. In particular, we show how the "interaction" is sum of two-body forces, what is the key for the solubility of these equations in the first place, and then calculate the phase shifts from inverse scattering (as a double-Darboux factorization), obtaining the known result, independent of the hierarchy, without ever using any of the KdV equations. We also obtain the Hirota formula for N solitons as a Wronskian, by creating them one by one from the $u(x) = 0$ potential.

1 Isospectral problem for finite matrices

Consider a Hermitian $n \times n$ matrix M and an automorphism $M \to M^{\#}$; as in any mathematical category, we are interested in the orbit $M/\{\mathrm{Aut}\}$. Now in a complete matrix algebra any automorphism is *inner*, that is

$$M \to M^{\#} = UMU^{-1} \tag{1}$$

with U unitary to preserve Hermiticity. The spectrum of M, $\mathrm{Spec}\, M$, is preserved, and we call it a hard datum. The orbit of a prefixed M is

$$\{M\} = U(n)/(\text{isotropy subgroup for } M) \equiv U(n)/H(M); \tag{2}$$

e.g. if $\mathrm{Spec}\, M$ is nondegenerate, that is for a generic M,

$$H(M) = U(1) \times \cdots \times U(1) \qquad \text{and} \qquad \{M\} = \text{Flag manifold} = U(n)/(U(1)^n). \tag{3}$$

So a generic Hermitian matrix is characterised by n different real numbers, the Spectrum, the hard datum, which is deformation invariant and $n^2 - n$ real numbers, variable under deformation, which specify the Orientation of M, and constitute the soft datum. The isospectral deformation changes the orientation but maintains the spectrum; it translates the matrix along the flag manifold.

At any moment the spectrum is retrieved from the powers of traces of the matrix by

$$I_k = (1/k)\,\mathrm{Tr}\, M^k, \tag{4}$$

i.e. $c_1 := \sum \lambda_i = I_1$, $c_2 := \sum_{i<j} \lambda_i \lambda_j = I_1^2/2 - I_2$, etc., where c_i are the elementary symmetric polynomials on the eigenvalues. Alternatively the spectrum is given by the poles of the resolvent

$$\mathrm{Res}\, M(\lambda) = [M - \lambda]^{-1}. \tag{5}$$

In the following we apply this analysis to the Schrödinger operator as a (infinite dimensional local) Hermitian operator.

2 Hard and soft data for the Schrödinger operator

Consider the Schrödinger equation on the real line $\mathbb{R}$; the operator is

$$H = -D^2 + u(x), \tag{6}$$

where $x \in \mathbb{R}$, $D \equiv d/dx$, and $u(x)$ is a real function decaying "fast enough" at $x \to \pm\infty$. There are *three* differences with the above finite case: infinite dimension, presence of continuous spectrum, and differential operator (the most general operator would be an *integral* operator). The data for the Discrete Spectrum are the bound states

$$H\Psi_j(x) = E_j\Psi_j(x), \qquad E_j < 0, \qquad j : 1, 2, \ldots, N, \qquad N+1 \in \mathbb{N}. \tag{7}$$

For $x \to +\infty$

$$\Psi_j(x) \to c_j \exp(-\kappa_j x), \qquad \|\Psi\| = 1, \qquad \kappa_j^2 = -E_j. \tag{8}$$

The *eigenvalues* E_i are the (discrete) hard data; the norming constants c_j localise the bound states; there are position (soft data), not spectral data. Note we take *normalised* discrete eigenfunctions.

Continuous Spectrum. It is contained in the *S-matrix*, which in our $1D$ case is a 2×2 matrix: we have forward/backward amplitudes for the direct and the *zurdo* scattering (zurdo or $\hat{}$: incoming particle form the right):

$$S(k) = \begin{pmatrix} t(k) & b(k) \\ \hat{b}(k) & \hat{t}(k) \end{pmatrix}, \qquad k \in [0, \infty). \tag{9}$$

Our potential is real so time reversal holds; hence $t(k) = \hat{t}(k)$; also by causality $t(k)$ is related to the *discrete* spectrum [1]; hence the forward amplitude is a hard datum, as part of the spectral density. There are also restrictions coming from the *unitarity* of S:

$$\begin{aligned} &S^\dagger S = 1 = SS^\dagger \Rightarrow |t|^2 + |b|^2 = |\hat{t}|^2 + |\hat{b}|^2 = 1, \\ &\operatorname{Arg} t + \operatorname{Arg} \hat{t} (= 2\operatorname{Arg} t) - \operatorname{Arg} b - \operatorname{Arg} \hat{b} = \pi. \end{aligned} \tag{10}$$

Hence the *argument* of either reflected amplitude (say, in direct scattering) is the soft datum for the continuous spectrum. Hence the complete data for the Schrödinger operator are

$\kappa_j (j : 1, \ldots, N)$ and $|b(k)|$ are hard data, fixed by $\operatorname{Spec} H$,
c_j and $\operatorname{Arg} b(k)$ are soft data, fixed by the Orientation of H.

In particular κ_j and $|b(k)|$ fix the *spectral density*. It is to be remarked that the natural "observables": energies E_j and scattering *coefficients* $\sigma_+ = |t(k) - 1|^2$ and $\sigma_- = |b(k)|^2$ are *hard data*.

3 Inverse problem

We just recall the usual procedure to recover the potential from the scattering data, cf. e.g. [2]. There are three steps:

1) Fourier transform of the total (soft + hard) data:

$$B(x) \equiv \frac{1}{2\pi} \int b(k)\, dk \exp(ikx) + \sum_j c_j^2 \exp(-\kappa_j x). \tag{11}$$

2) Solve for the kernel $K(x,y)$ in the Marchenko integral equation

$$K(x,z) + B(x+z) + \int_x^\infty K(x,y)B(y+z)dy = 0. \tag{12}$$

3) Retrieve the potential by

$$u(x) = -2K_x(x,x), \qquad \text{where} \quad K_x \equiv dK/dx. \tag{13}$$

Notice the solution is complete, i.e. we recover the full potential, and hence both the hard and the soft data are used. For example, for the *solitonic potentials* (defined as reflectionless potentials by $b(k) \equiv 0$), it is

$$u(x) = -2\big(d^2/dx^2\big) \log \det A, \tag{14}$$

where

$$A_{mn} = \delta_{mn} + c_n^2[\exp -(\kappa_m + \kappa_n)x]/(\kappa_m + \kappa_n), \tag{15}$$

where the discrete spectrum data κ_j, c_j are given arbitrarily, subject only to all eigenvalues κ_j different. For example for $N = 1$ $\{\kappa, c\}$ we recover the one soliton potential $u(x) = -2\kappa^2 \operatorname{sech}^2\kappa(x - x_0)$, where $E = -\kappa^2$ and $c = \sqrt{2\kappa}\exp(\kappa x_0)$.

The exponential part in (15) is related to the soliton scattering phase shift for any of the KdV hierarchy equations (see later); we have approached it here from inverse scattering theory, with no reference to the hierarchy at all! (15) was first obtained by Kay and Moses [3] from inverse scattering and later by Hirota [4] from his bilinear method. We shall obtain it below also by the Darboux method.

4 General isospectral problem

We know that the KdV equations are isospectral evolution equations; hence, their solutions $u(x) = u(x, t = 0) \to u(x,t)$ are a particular case of the general isospectral problem. It is this: *given a potential $u(x)$, find the most general potential $v(x)$ with the same hard data.* The formal solution of the inverse problem sketched above allows us to set and solve, in principle, the general isospectral problem: There are again three steps:

1) Solve the direct problem for $u(x)$: find

$$\kappa_j, \quad c_j, \quad |b(k)| \quad \text{and} \quad \operatorname{Arg} b(k). \tag{16}$$

2) Change arbitrarily the soft data c_j and $\operatorname{Arg} b(k)$.

3) Solve the inverse problem from the new c and $b(k)$.

Then the new potential $v(x)$ is the most general potential strictly isospectral to $u(x)$.

Some restrictions apply: for example, the new $b(k)$ has to be "nice", i.e. to admit Fourier transform guaranteeing that the new potential $v(x)$ falls off at infinity fast enough. Also c_j have to be positive (by an initial convention).

From the above it is clear that the KdV equations realize part of this program; before seeing it in detail, let us consider the simplest case: to obtain the most general potential isospectral to the standard one-soliton potential

$$u(x) = -2\operatorname{sech}^2(x); \tag{17}$$

it has a single bound state with $\kappa = 1$, $c = \sqrt{2}$ and it is reflectionless, $b(k) = 0$. To change the soft data means just to change $\sqrt{2}$ to an arbitrary c; then the inverse method produces inmediately

$$v(x) = -2\operatorname{sech}^2(x - x_1), \qquad \text{with} \quad x_1 = \log\big(c/\sqrt{2}\big). \tag{18}$$

The only effect on the potential is just a traslation of the "well", where the soliton is located.

We shall see now that two methods: the Double Darboux method (DD) and the KdV hierarchy are equivalent to finding deformed isospectral potentials in somewhat complementary ways from a given potential. We first dispose of the DD method [5].

In the simplest application of the DD method one kills the ground state and reinserts it in another "position"; therefore, it changes only the first norming constant c_1. The procedure is constructive, i.e. the new ground state wavefunction is calculated completely from the original one (see e.g. [6]):

$$\Psi(x,\lambda) = \Psi(x)/[1+\lambda\int_{-\infty}^{x}\Psi^2(x)\,dx], \tag{19}$$

and therefore the new norming constant is (as $\|\Psi\| = 1$)

$$c_1' = c_1/(1+\lambda). \tag{20}$$

The iterated DD method repeats the process changing simultaneously the positions of two or more arbitrary bound states (by killing and reinstating them somewhere else), and leaving the phases of the reflection amplitudes unchanged. The procedure can be always implemented (and indeed, not only for fast-decaying potentials), and the solutions are also algebraic, but the procedure is cumbersome and tedious!

The original method was devised by Darboux (1882) [5] to relate linear differential operators, not necessarily of second order. The general application to solutions of the Schrödinger equation was found by Abraham and Moses (1980) [6], Mielnick (1984) [7] and others.

5 The KdV hierarchy

The Korteweg–de Vries equation ($\mathrm{KdV} = \mathrm{KdV}_1$) was discovered in 1895 as an equation exhibiting soliton behaviour, and the hierarchy KdV_n was first presented by P. Lax (1968) [8]. The time evolution of the solutions of the equations of the KdV hierarchy, $u(x) \to u(x,t)$ represents the isospectral change of the Hamiltonian of the Schrödinger equation by an uniparametric group of automorphims whose generator is polynomial in the derivatives.

In the beautiful exposition of Lax (1970) [8], we have

$$H \to H(t) = U(t)HU^{-1}(t). \tag{21}$$

Define $B(t)$ by $B(t) = (dU(t)/dt)U^{-1}(t)$. Then

$$H_t = [B,H], \qquad u_t = K[u], \qquad \text{and} \qquad \Psi_t = B\Psi \tag{22}$$

with $a_t = \partial a/\partial t$ throughout. Then the first equation defines the problem (i.e., to find B). The second equation is the Non-Linear evolution equation (KdV hierarchy). The third equation is important for the evolution of the scattering data.

The KdV hierarchy obtains solving for B order by order in derivatives:

$B = D$: The equation is $u_t = u_x$; the chiral wave equation.

$B = D^3 + \{u, D\}$. The equation is, of course

$$u_t = 6uu_x - u_{xxx}, \qquad (\text{Korteweg–de Vries}, 1895) \tag{23}$$

with a cubic dispersion law. There are at least one equation of each odd order of dispersion; for systematics we just write the (natural) quintic equation [9]

$$u_t = -30u^2u_x + 20u_xu_{xx} + 10uu_{xxx} - u_{xxxxx}. \tag{24}$$

The key point why these hierarchical equations can be solved *inspite of being partial and nonlinear* is that *the scattering data of the potential change with the linear part of the operator B only*, which has the highest derivative: the rest is function of the potential u, and goes to zero faster, as u itself decays fast.

Let us interpret the evolution in the original KdV equation, with cubic dispersion law, as an one-parameter isospectral deformation; at time t (=deformation parameter), the hard data are of course invariant:

$$\kappa_j(t) = \kappa_j(0), \qquad |b(k,t)| = |b(k,0)|, \tag{25}$$

but the soft data evolve in a simple manner:

$$c_j(t) = \exp\left(4\kappa_j^3 t\right) c_j(0), \qquad b(k,t) = \exp\left(8ik^3 t\right) b(k,0), \tag{26}$$

i.e. the "bumps" of the bound state wavefunctions move all harmonically, and only the phase of the reflected amplitudes changes. As it is expected, the other equations in the KdV hierarchy just trade, as far as soft data are concerned, the cubic "3" of KdV_1 for any greater odd number.

It is interesting the comparison of the Double Darboux method and the KdV solutions for new potentials:

– In the DD method, we change one position of the discrete spectrum at a time arbitrarily.

– With the KdV equations, we change all the soft data with a particular dispersion law.

6 Irrelevance of the KdV hierarchy

It is common lore that the "nonlinear" character of the KdV equations is the agent responsible for the phase shift in soliton-soliton scattering; the shift is obtained from the asymptotic behaviour, of course; now the motion of the solitons through space means the centers x_i (or the norming constants c_i) move with a particular dispersion law, but of course they are irrelevant at the asymptotic limit: initial $x_i \to -\infty$, final $x_i \to +\infty$. We conclude, therefore, that the phase shift is a hard datum; hence, we should be able to get it directly from the Schrödinger equation; this we show next, limiting ourselves to the case of two solitons.

To create two arbitrary solitons we use the direct Darboux method twice starting from the $u(x) = 0$ solution, the vacuum [10]. The procedure is well known, so we just quote some formulas and results:

Take the $E_1 = -\kappa_1^2$, unphysical solution $\phi_1(x) = \cosh \kappa_1(x - x_1)$. Factorize $H - E_1 = A^\dagger A$, where $A = D + W' = \phi_1 \cdot D \cdot \phi_1^{-1}$ with $\phi_1(x) = \exp(-W)$. The new, first step potential is

$$v_1(x) = -2\kappa_1^2 \operatorname{sech}^2(x - x_1). \tag{27}$$

To create the second solution, with $E_2 < E_1$, take now the free solution $\phi_2(x) = \sinh \kappa_2(x - x_2)$, which becomes a zeroless unphysical solution of the first step potential by

$$\tilde{\phi}_2(x) = A\phi_2(x) = (D - \tanh \kappa_1(x - x_1))\phi_2(x) = \phi_1 \cdot D \cdot \phi_1^{-1}\phi_2(x). \tag{28}$$

The new potential is now

$$v_2(x) = -2D^2 \log \phi_1(x) - 2D^2 \log \tilde{\phi}_2(x) = -2D^2 \log W(\phi_1(x), \phi_2(x)), \tag{29}$$

where W is the *Wronskian* $W = \phi_1(x)\phi_2'(x) - \phi_2(x)\phi_1'(x)$.

This is an *exact* solution of the two soliton potential; to compute the phase shift we let now $x_2 \to -\infty$ and compare the new center of the remaining (original) soliton x_1' with the original x_1; the phaseshift is twice this value times κ_1 (as Φ is dimensionless): as the second soliton is created

at $x = -\infty$, the first gets repelled and moves a distance $x_1' - x_1$: when the bigger soliton moves to $+\infty$, the old one recedes to $-x_1' - x_1$.The messy algebra leads to a well known expression (recall $\kappa_2 > \kappa_1$)

$$\Phi = \log(\kappa_2 + \kappa_1)/(\kappa_2 - \kappa_1) \tag{30}$$

checked numerically (it is enough to take $\kappa_1 = 1$, and $x_1 = 0$). The second soliton repels the first by a sort of exclusion principle: the bound eigenvalues of the Schrödinger equations are nondegenerate, hence $\kappa_1 = \kappa_2$ would lead to an infinite phase shift, and "by continuity" we get (30); writing it in the form

$$\Phi = 2\,\mathrm{Arg}\,\tanh(\kappa_1/\kappa_2) \tag{31}$$

looks like a very common formula is scattering theory (with arc tan instead; recall κ is like an imaginary wavenumber; our shift is not really a phase shift, as it is not periodic; it is more a space (vs time) delay). For instance, scattering for a point impurity of strength g produces an even phase shift [11] $\mathrm{tg}\,\delta_+ = g/k$.

Formula (30) is of course obtained from the KdV_n equations: the generalization for n solitons leads, from KdV, to the Hirota formula [4]; in our method we get directly the Wronskian for n independent $E < 0$ free solutions; the identity of the Kay–Moses & Hirota formula with the Wronskian we leave to the reader to check; for this is essential to use the affine invariance of the equation (14), namely $\det A = \det BA$, where B is a column matrix with entries $\exp(a_i x + b_i)$, up to terms which die in calculating the potential.

Notice also the full n-soliton interaction is sum of independent two-body "forces", which accounts for the completely solubility of the system.

7 Singular solutions

We can see also how many special solutions, common to all KdV hierarchy equations, are obtained directly by the Darboux method starting again from the $u(x) = 0$ potential. For example, the first step of the $u(x) = 0$, $E = 0$ solution $\phi(x) = ax + b$ produces the centrifugal potential

$$u(x) = +2/(x - x_1)^2 \tag{32}$$

which is also a rational solution of KdV. Iteration with the $\phi_2(x) = x^2$ solution produces e.g.

$$u(x) = 6x\big(x^3 - 24x_1\big)/\big(x^3 + 12x_1\big)^2 \tag{33}$$

which again is a rational solution of KdV (with $t = x_1$) (cf. [9]).

8 Final remarks

Soliton properties, including scattering, are really properties of the Schrödinger operator. In particular, the one-soliton potential is just the partner potential to the vacuum potential $u(x) = 0$ doubled by the (unphysical, negative energy) solution $\phi(x) = \cosh(x)$. The iteration, always with negative energy, will produce the most general multi-soliton solution at any x, hence should reproduce the phase shifts, as we checked for the two soliton case; solitons "forces" are exclusively the effect of non-degeneracy of the normalizable eigenfunctions.

As the solitons move in one direction only, they behave as chiral fields. In the Lagrangian formulation, these chiral fields are rather peculiar, because the space of potentials $\{u\}$ (or rather

of the integrals $\varphi = \int u$, which is what enters in the local Lagrangian) is already the phase space, not the configuration space. This implies, in particular, that in the quantum version the solitons should behave like fermions (Jackiw proved this directly for the chiral, KdV_0 case [12]). This fermi character is a translation, we believe, of the purely classical effect: namely two solitons of close wavenumber cannot superpose (P. Lax), reflecting the case that for equal wavenumber they should be at infinite distance, because the Schrödinger equation does not allow degeneracy in the bound states in one dimension.

We believe also that upon quantization these solitons should behave like nonrelativistic Majorana–Weyl fermions, reflecting the "chiral" behaviour of the classical counterpart. But we have not looked carefully yet to the quantization problem.

On the Use of the Lie–Bäcklund Groups in the Context of Asymptotic Integrability

Georgy I. BURDE

The Jacob Blaustein Institute for Desert Research,
Ben-Gurion University, Sede Boker Campus 84990, Israel
E-mail: *georg@bgumail.bgu.ac.il*

A new approach to the problem of asymptotic integrability of physical systems is developed and applied to the KdV equation with higher-order corrections. A central object of the approach is an integrable reference equation, which is constructed by defining a proper Lie–Bäcklund group of transformations and applying it to the leading order equation. It is shown that the solitary wave solutions of the asymptotically integrable equations, derived using asymptotic transformations, fail to approximate solutions of those equations in some (rather wide) range of the soliton and system parameters.

1 Introduction

For many important physical systems, the leading order term in an asymptotic perturbation expansion is given by an integrable nonlinear equation. This implies that those physical systems are integrable at the nontrivial leading orders in an asymptotic sense. The meaning of the term "asymptotic integrability" is that the equation with higher-order corrections is integrable up to a certain order in the asymptotic sense. Asymptotic integrability at certain order is commonly ascertained by developing an asymptotic transformation relating this higher-order equation to an integrable equation. If such a transformation is impossible, the nonintegrable effects (the "obstacles" to integrability [1]) are defined as additional terms appearing in the target equation.

The most extensively studied example is that of weakly nonlinear long waves, when the leading order equation is the Korteweg–de Vries (KdV) equation. The KdV equation first arose as an approximate equation governing the unidirectional small amplitude long waves in inviscid incompressible fluid [2] but later it was introduced in many different physical contexts. If effects of higher-order are of interest, then extension of terms up to the next orders in the (small) wave amplitude, with the weakly nonlinear and weakly dispersive effects being in balance, leads to the extended KdV equation including higher-order corrections. The KdV equation with the first-order corrections is integrable in the asymptotic sense as it has been shown by Kodama [3] (see also [4]) who has found a transformation which maps the perturbed KdV equation to the integrable equation (normal form) obtained by combining the KdV equation with its first commuting flow. In [4], the normal form was introduced up to the second-order corrections. It was found that, in general, the asymptotic integrability cannot be extended to the second-order, and the asymptotic transformation from the second order KdV equation to the equation representing a normal form plus one obstacle was defined.

It is commonly accepted that the asymptotic transformations from the high-order KdV equations to the corresponding integrable equation (if there are no obstacles), or to the form given by the symmetries plus obstacles, can be used for investigating the properties of the high-order KdV solitons (see, e.g. [5,6]).

In the present paper, we develop an approach allowing us to study the approximation properties of the asymptotic solutions of the higher-order KdV equations that are obtained by Kodama's asymptotic transformation from the normal form solitary waves. Our approach, as

applied in the context of asymptotic integrability, is aimed at constructing some asymptotically integrable higher-order KdV equations, for which the asymptotic solutions, alternative to those derived via Kodama's transformation, may be defined. The central object of the approach is some reference integrable equation, which depends on a small parameter of the physical system in such a way that its asymptotic perturbation expansion, to a certain order, has a form of the corresponding order KdV equation. The reference integrable equation is constructed by applying the properly defined Lie–Bäcklund group of transformations to the leading order equation.

2 The reference equation

We will consider a physical system that can be described by an asymptotic perturbation expansion with the leading order term given by an integrable nonlinear equation. We will assume the following expansion form with a small parameter ϵ and a leading order term representing a scalar differential equation:

$$F^{(0)}(x,u,u_{(1)},u_{(2)},\dots,u_{(k)})+\epsilon F^{(1)}(x,u,u_{(1)},u_{(2)},\dots,u_{(k+r)}) \\ +\epsilon^2F^{(2)}(x,u,u_{(1)},u_{(2)},\dots)+\dots+\epsilon^NF^{(N)}(x,u,u_{(1)},u_{(2)},\dots)=O\big(\epsilon^{N+1}\big), \tag{1}$$

where $x=(x^1,x^2,\dots,x^n)$ are n independent variables, u is the dependent variable, and $u_{(j)}$ denotes the set of all jth-order partial derivatives of u with respect to x.

Following the ideas of the approach, developed in [7] for the point transformations, we will consider the one-parameter (a) group of the Lie–Bäcklund transformations

$$\bar u=\phi(x,u,u_{(1)},u_{(2)},\dots;a) \tag{2}$$

with (canonical) Lie–Bäcklund infinitesimal generator

$$U=\eta(x,u,u_{(1)},u_{(2)},\dots)\frac{\partial}{\partial u}, \tag{3}$$

where the order of derivatives appearing in the generator is, in general, not restricted.

The group (2) is defined from the requirement that the leading order equation transform, under an infinitesimal action of the group (for small values of the group parameter $a=\epsilon$), into the first-order perturbed equation obtained by retaining only the leading order and first-order terms in (1), as follows

$$F^{(0)}(x,u,u_{(1)},u_{(2)},\dots,u_{(k)})+\epsilon F^{(1)}(x,u,u_{(1)},u_{(2)},\dots,u_{(k+r)})=0. \tag{4}$$

To define the group the following steps are made:

(i) The group (2) is applied to the *unperturbed equation* $F^{(0)}=0$ written in the variables $\bar u$, $\bar u_{(1)}$ and so on, as

$$F^{(0)}(x,\bar u,\bar u_{(1)},\bar u_{(2)},\dots,\bar u_{(k)})=0. \tag{5}$$

As the result, equation (5) is transformed to

$$H(x,u,u_{(1)},u_{(2)},\dots,u_{(s)};a)=0 \tag{6}$$

or infinitesimally

$$F^{(0)}(x,\bar u,\bar u_{(1)},\bar u_{(2)},\dots,\bar u_{(k)})=F^{(0)}(x,u,u_{(1)},u_{(2)},\dots,u_{(k)}) \\ +aU^{(k)}F^{(0)}(x,u,u_{(1)},u_{(2)},\dots,u_{(k)})\Big|_{[F^{(0)}]}+O\left(a^2\right)\qquad(a\ll1), \tag{7}$$

where $U^{(k)}$ is the kth extended infinitesimal generator of (3) defined by

$$U^{(k)} = \eta\frac{\partial}{\partial u} + D_j(\eta)\frac{\partial}{\partial u_j} + D_iD_j(\eta)\frac{\partial}{\partial u_{ij}} + \cdots \tag{8}$$

and $[F^{(0)}]$ denotes the set of equations including the equation $F^{(0)} = 0$ and its differential consequences:

$$D_iF^{(0)} = 0, \qquad D_iD_jF^{(0)} = 0, \qquad \ldots. \tag{9}$$

(ii) It is required that

$$U^{(k)}F^{(0)}(x, u, u_{(1)}, u_{(2)}, \ldots, u_{(k)})\Big|_{[F^{(0)}]} = F^{(1)}(x, u, u_{(1)}, u_{(2)}, \ldots, u_{(k+r)}). \tag{10}$$

It yields determining equations for the Lie–Bäcklund group generator $\eta(x, u, u_{(1)}, u_{(2)}, \ldots)$.

(iii) With the group generator defined, the finite transformations (2) can be determined as a solution of the Lie–Bäcklund equation

$$\frac{d\bar{u}}{da} = \eta(x, \bar{u}, \bar{u}_{(1)}, \bar{u}_{(2)}, \ldots), \qquad \bar{u}|_{a=0} = u(x). \tag{11}$$

It is evident from (i)–(iii) that the group (2) defined in such a way is neither a symmetry group of equation (1) nor a symmetry group of the unperturbed equation.

In some cases, for specific relations among the coefficients of differential monomials in the first-order term of (1), the Lie–Bäcklund equation (11) can be solved in a closed form so that the finite transformation (2) is represented by an analytical function. Using this closed form transformation one can construct the equation (6) in an explicit form (not as a series). This new equation is dependent on a parameter a (for the sake of brevity we will name it the "a-equation") and possesses the following properties:

a) The a-equation is integrable, since there exists an exact transformation (inverse to (2)) that converts equation (6) into the leading order integrable equation (5). Therefore any exact solution of equation (5) yields the exact solution of the a-equation.

b) When $a \ll 1$, the a-equation coincides with the initial perturbed equation (1) up to first-order in $a = \epsilon$.

c) In the case when (1) is an evolution equation and the x-derivative terms at each order represent differential polynomials of specific weights, the corresponding order terms in an expansion of the a-equation in series with respect to a have the same differential structure as those in the original equation but with the monomial coefficients specified in a certain way.

In view of the property (c), the a-equation can be considered as a model for the original physical system in a sense, since it contains impacts of all orders of the asymptotic perturbation expansion on the solution. This model may correspond to a real physical system if there are enough freedoms to satisfy the required conditions on the coefficients.

From another point of view, an expansion of the a-equation up to a certain order produces equations that can be treated as asymptotically integrable at this order since the equation expanded is exactly integrable and the terms dropped may be considered as having an asymptotically negligible influence upon the solution.

3 Applications to the higher-order KdV equations

It can be shown with the use of an appropriate perturbation method (e.g., see [2]) that the higher-order correction to the KdV equation has the following expansion form with a small parameter ϵ:

$$u_t + K^{(0)}[u] + \epsilon K^{(1)}[u] + \epsilon^2 K^{(2)}[u] + \cdots + \epsilon^N K^{(N)}[u] = O\big(\epsilon^{N+1}\big), \tag{12}$$

where $K^{(0)}[u]$ gives the KdV flow in its standard form

$$K^{(0)}[u] = u_3 + 6uu_1 \tag{13}$$

and the next two terms in (12) are given by

$$K^{(1)}[u] = a_1^{(1)}u_5 + a_2^{(1)}u_3u + a_3^{(1)}u_2u_1 + a_4^{(1)}u_1u^2, \tag{14}$$

$$K^{(2)}[u] = a_1^{(2)}u_7 + a_2^{(2)}u_5u + a_3^{(2)}u_4u_1 + a_4^{(2)}u_3u^2 + a_5^{(2)}u_3u_2 + a_6^{(2)}u_2u_1u + a_7^{(2)}u_1u^3 + a_8^{(2)}u_1^3. \tag{15}$$

The subscript t denotes derivatives with respect to time variable and other subscripts denote derivatives of the corresponding order with respect to the space variable x. Each polynomial $K^{(n)}[u]$ has the scaling property with the homogeneous weight $2n+5$ if one assigns the weight 2 to u and 1 to $\partial/\partial x$.

Following the approach described in the previous section, we consider the one-parameter (a) Lie–Bäcklund group of transformations

$$\bar{u} = \phi(x, t, u, p, u_1, u_2, \ldots; a), \qquad U = \eta(x, t, u, p, u_1, u_2, \ldots)\frac{\partial}{\partial u}, \tag{16}$$

where the nonlocal terms containing

$$p = D^{-1}(u), \qquad D^{-1}(\cdot) = \int_{-\infty}^{x} (\cdot)dx' \tag{17}$$

may appear. The transformation (16) is defined by the requirement that it converts the leading order equation $u_t + K^{(0)}[u] = 0$ written in the variables $\bar{u}$, $\bar{u}_1$ and so on, as

$$F^{(0)}(\bar{u}) = \bar{u}_t + \bar{u}_3 + 6\bar{u}\bar{u}_1 = 0 \tag{18}$$

into a new equation $H(u; a) = 0$ which possesses the property that, for small values of the group parameter a, it coincides with the perturbed equation (12) up to first-order in $a = \epsilon$:

$$H(u; a) = u_t + K^{(0)}[u] + aK^{(1)}[u] + O\left(a^2\right) \qquad (a \ll 1). \tag{19}$$

Applying this requirement (expressed in terms of the group generator by (10)) yields determining equations for the Lie–Bäcklund group generator $\eta(x, t, u, p, u_1, u_2, \ldots)$.

It is evident that the generator $\eta(x, t, u, p, u_1, u_2, \ldots)$ defined in such a way is not unique since, in addition to the terms depending on the coefficients $a_1^{(1)}, \ldots, a_4^{(1)}$ of the differential polynomial $K^{(1)}[u]$, it may include the terms representing symmetries of the leading order equation $F^{(0)}(u) = 0$ with arbitrary coefficients. In what follows, we will deal with a minimal form of the group generator excluding symmetries, since only it yields the transformation generating the a-equation possessing the property (c): the terms of its expansion with respect to a, at each order, represent differential polynomials of the homogeneous weight like (14), (15) and so on. This minimal form is uniquely defined from the determining equations yielded by (10) as

$$\eta = \lambda_1 u^2 + \lambda_2 u_2 + \lambda_3 u_1 p + \lambda_4 x(u_3 + 6uu_1) \tag{20}$$

or equivalently as

$$\eta = \lambda_1 u^2 + \lambda_2 u_2 + \lambda_3 p u_1 - \lambda_4 x u_t, \tag{21}$$

where the parameters $\lambda_1, \ldots, \lambda_4$ are expressed through the coefficients $a_1^{(1)}, \ldots, a_4^{(1)}$ of $K^{(1)}[u]$ by the relations

$$\lambda_1 = \frac{1}{6}\left(a_4^{(1)} - a_2^{(1)} - 4a_1^{(1)}\right), \qquad \lambda_2 = \frac{1}{12}\left(a_4^{(1)} - a_3^{(1)} + 6a_1^{(1)}\right),$$
$$\lambda_3 = \frac{1}{3}\left(a_2^{(1)} - 8a_1^{(1)}\right), \qquad \lambda_4 = \frac{1}{3}a_1^{(1)}. \tag{22}$$

It is seen that the group generator depends explicitly on x but it does not contain t.

With the group generator defined, the finite transformations (16) are determined as a solution of the Lie–Bäcklund equation

$$\frac{d\bar{u}}{da} = \lambda_1\bar{u}^2 + \lambda_2\bar{u}_2 + \lambda_3\bar{u}_1\bar{p} + \lambda_4 x(\bar{u}_3 + 6\bar{u}\bar{u}_1), \qquad \bar{u}|_{a=0} = u(x,t), \tag{23}$$

where, alternatively, the expression for η on the right-hand side, may be defined as in (21). We will concentrate on the cases where the Lie–Bäcklund equation (23) can be solved in a closed form, which correspond to the specific relations between the coefficients $a_1^{(1)}, \ldots, a_4^{(1)}$ of the differential polynomial $K^{(1)}[u]$.

In the present paper, we will consider only the following case

$$a_2^{(1)} = 8a_1^{(1)}, \qquad a_3^{(1)} = a_4^{(1)} + 6a_1^{(1)} \tag{24}$$

which, according to (22), corresponds to the generator (21) with the coefficients λ_2 and λ_3 vanishing. Then the Lie–Bäcklund equations (23) can be solved to give

$$\bar{u}(x,t;a) = \frac{u(\xi,\tau)}{1 - a\lambda_1 u(x,\tau)}, \qquad \xi = x, \qquad \tau = t - a\lambda_4 x, \tag{25}$$

where

$$\lambda_1 = \frac{a_4^{(1)}}{6} - 2a_1^{(1)}, \qquad \lambda_4 = \frac{a_1^{(1)}}{3}. \tag{26}$$

In (25), $\bar{u}$ is a solution of the KdV equation (18) and u is a solution of the reference equation $H(u;a) = 0$ which possesses the property (19). The equation for $u(\xi,\tau)$ obtained by substituting (25) into (18) is

$$H(u;a) = \frac{1}{a^4\lambda_1^4 v^4}\Big\{6a^2\lambda_1^2\left[L(v)\right]^3 - 6vL(v)\left[1 + a^2\lambda_1^2 L^2(v)\right]$$
$$+ a\lambda_1 v^2\left[a\lambda_1 v_\tau - 6L(v) + a\lambda_1 L^3(v)\right]\Big\} = 0, \tag{27}$$

where

$$v = u - \frac{1}{a\lambda_1}, \qquad L = \frac{\partial}{\partial\xi} - a\lambda_4\frac{\partial}{\partial\tau}. \tag{28}$$

The a-equation (27) treated as an equation for $u(x,t)$ is dependent on a – not only explicitly but also through the independent variable τ as is defined in (25). It possesses the properties (a)–(c) formulated in the previous section. Solutions of the a-equation (27) can be obtained from solution of the integrable KdV equation (18) by the transformation (inverse to (25):

$$u(x,t;a) = \frac{\bar{u}(x,z)}{1 + a\lambda_1\bar{u}(x,z)}, \qquad z = t + a\lambda_4 x, \tag{29}$$

where $\bar{u}(x,z)$ satisfies $\bar{u}_z + \bar{u}_3 + 6\bar{u}\bar{u}_1 = 0$.

Despite the fact that the maximal order of derivatives in equation (27) is three – the same as in the leading order equation, its expansion in to series with respect to a includes the terms with higher-order derivatives (which appear due to the a-dependence of the independent variable τ), and those high-order terms have the same differential structure as the corresponding order terms in the original equation (12). However, the monomial coefficients in the higher-order terms are now specified in a certain way.

In the expansion of equation (27), the coefficients in the first-order term are specified according to (24). We will also write out the relations defining the monomial coefficients in the second-order term

$$\begin{aligned}
&a_1^{(2)} = \frac{4}{3}a_1^{(1)^2}, \qquad a_2^{(2)} = 14a_1^{(1)^2}, \qquad a_3^{(2)} = \frac{1}{3}a_1^{(1)}\left(84a_1^{(1)} + 5a_4^{(1)}\right),\\
&a_4^{(2)} = \frac{4}{3}a_1^{(1)}\left(18a_1^{(1)} + a_4^{(1)}\right), \qquad a_5^{(2)} = \frac{2}{3}a_1^{(1)}\left(66a_1^{(1)} + 5a_4^{(1)}\right),\\
&a_6^{(2)} = 36a_1^{(1)^2} + 10a_1^{(1)}a_4^{(1)} + \frac{1}{6}a_4^{(1)^2}, \qquad a_7^{(2)} = \frac{1}{6}a_4^{(1)^2}, \qquad a_8^{(2)} = \frac{1}{6}a_4^{(1)}\left(12a_1^{(1)} + a_4^{(1)}\right).
\end{aligned} \tag{30}$$

4 Asymptotic integrability

The analysis made in [4] is based on a near identity transformation $T_\epsilon : v \to u$

$$u = T_\epsilon(v) = v + \epsilon\Phi^{(1)}(v) + \cdots \tag{31}$$

such that the perturbed KdV equation (12) is transformed to

$$v_t + K^{(0)}[v] + \epsilon G^{(1)}[v] + \epsilon^2 G^{(2)}[v] + \cdots + \epsilon^N G^{(N)}[v] = O\big(\epsilon^{N+1}\big), \tag{32}$$

where $G^{(n)}(v)$ are differential polynomials of the same structure as the corresponding polynomials in (12). In particular, if the calculations are aimed at defining obstacles to the asymptotic integrability, then $G^{(n)}(v)$ are represented as

$$G^{(n)}(v) = a_1^{(n)}K_0^{(n)}(v) + R^{(n)}(v), \qquad R^{(n)}(v) = \sum_{i=1}^{\Delta(n)} \mu_i^{(n)} R_i^{(n)}(v). \tag{33}$$

Here $K_0^{(n)}(v)$ are symmetries of the leading order KdV equation. The number $\Delta(n)$ in (33) is the total number of the conditions $\mu_i^{(n)} = 0$ (number of obstacles) needed to be satisfied for existence of a transformation to the normal form containing only symmetries.

At order ϵ, the transform T_ϵ is given by the first-order term $\Phi^{(1)}$ of the generating function. There is no obstacles to asymptotic integrability at the first-order. The transform T_ϵ at the next orders is defined via an expansion of the generating function Φ in the power series of ϵ [4]. At order ϵ^2, there is one obstacle to asymptotic integrability, which means that one condition on the coefficients $a_1^{(1)}, \ldots, a_4^{(1)}, a_1^{(2)}, \ldots, a_8^{(2)}$ needs to be satisfied for existence of a transformation to the normal form.

We will study the approximate solitary wave solutions for the KdV equation (12) of a specific form, namely, one with the first- and second-order corrections given by the terms of an expansion of the a-equation (27) in series with respect to a. There is no obstacle to asymptotic integrability of this equation via Kodama's transformation to the normal form – the relations (24) and (30), defining the expansion of the a-equation (27) satisfy the condition for vanishing the obstacle.

The one-soliton solution of the leading order KdV equation and the corresponding solution of the second-order normal form are

$$u = 2k^2\mathrm{sech}^2\left[k\left(x - 4k^2t\right)\right], \tag{34}$$

$$v = 2k^2\mathrm{sech}^2\left\{k\left[x - \left(4k^2 + 16\epsilon a_1^{(1)}k^4 + 64\epsilon^2 a_1^{(2)}k^6\right)t\right]\right\}, \tag{35}$$

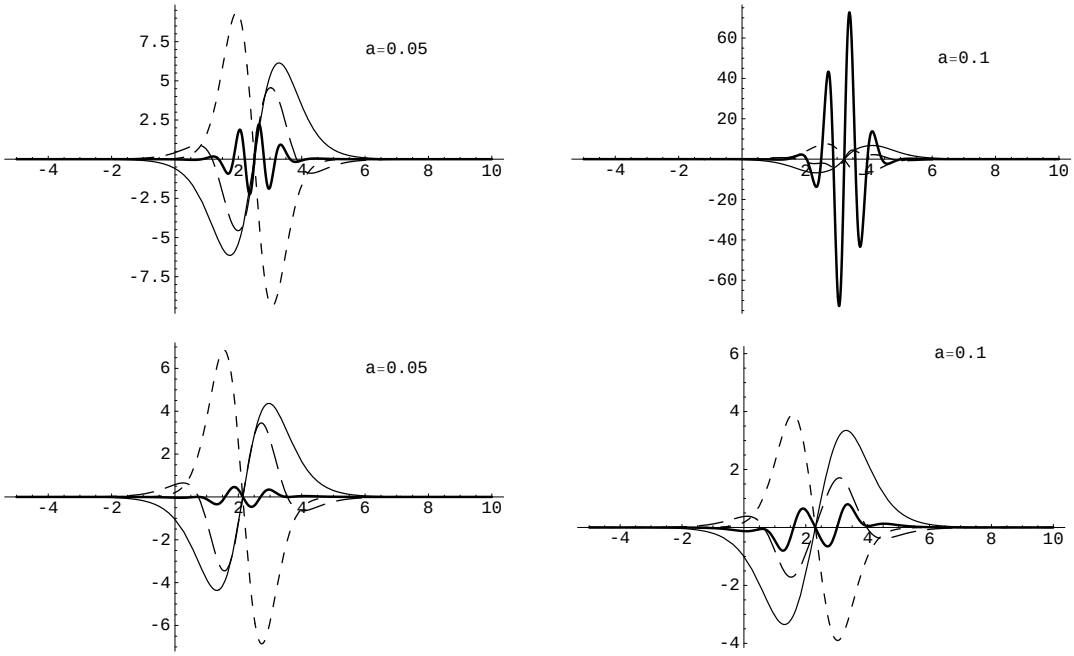

Figure 1. A residual error for the solutions of the second-order KdV equation defined by (24) and (30) in comparison with the terms of the leading order KdV equation (thick solid for the error, thin solid for u_t, short-dashed for $6uu_x$ and long-dashed for u_{xxx}): for the solution (36) obtained by Kodama's transformation ($\epsilon = a$) from the normal form solitary wave (top) and for the solution (37) of the a-equation (bottom). For both solutions $a_1^{(1)} = 1$, $a_4^{(1)} = 30$, $k = 1$.

where a phase constant has been omitted for the sake of simplicity. Applying Kodama's transformation to the solution (35) yields

$$\begin{aligned} u(x,t) = {} & 2k^2\mathrm{sech}^2 Z + \frac{2}{3}\epsilon k^4\left(16a_1^{(1)} - a_4^{(1)} + 4a_1^{(1)}\cosh 2Z\right)\mathrm{sech}^4 Z \\ & + \frac{2}{9}\epsilon^2 k^6\left(282{a_1^{(1)}}^2 - 32a_1^{(1)}a_4^{(1)} + {a_4^{(1)}}^2 + 8a_1^{(1)}\left(19a_1^{(1)} - a_4^{(1)}\right)\cosh 2Z\right. \\ & \left. + 14{a_1^{(1)}}^2\cosh 4Z\right)\mathrm{sech}^6 Z, \qquad Z = k\left[x - \left(4k^2 + 16\epsilon a_1^{(1)}k^4 + \frac{256}{3}\epsilon^2{a_1^{(1)}}^2k^6\right)t\right]. \end{aligned} \tag{36}$$

It is readily checked that this solution satisfies the second-order KdV equation with the coefficients defined by (24) and (30) if the terms of the order ϵ^3 are dropped.

Applying the transformation (29) to the solution (34) yields the corresponding one-soliton solution of the a-equation (27), as follows:

$$u = \frac{12k^2}{3 + 2a\left(a_4^{(1)} - 12a_1^{(1)}\right)k^2 + 3\cosh\left\{2k\left[x - 4k^2\left(t + \frac{aa_1^{(1)}x}{3}\right)\right]\right\}}. \tag{37}$$

The results presented in Fig. 1 and Fig. 2 demonstrate that the solitary wave solutions, constructed from the normal form solitons using a near identity transformation, although being formally asymptotic solutions of the higher-order KdV equations, have very bad approximation properties for the values of the soliton wave-number k larger than one. Even for $k = 1$ an acceptable approximation is achieved only for values of the expansion parameter $\epsilon \sim 10^{-2}$. For $k = 2$ (the second soliton in Fig. 2) the solution is invalid already for $\epsilon < 10^{-2}$.

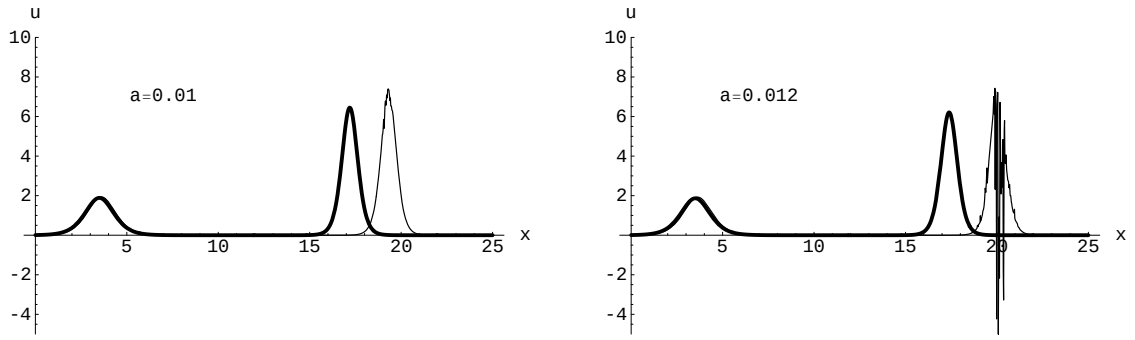

Figure 2. Comparison of different two-soliton ($k_1 = 1$; $k_2 = 2$) solutions of the KdV equation defined by (24) and (30) at $t = 1$: thick solid – the solution of the a-equation; thin solid – the solution obtained by Kodama's transformation ($\epsilon = a$) from the second-order normal form two-soliton solution. For both solutions $a_1^{(1)} = 1$, $a_4^{(1)} = 30$.

It should be noted in this connection that the solutions constructed via Kodama's transformation are ones of an excessive accuracy. For example, in the one-soliton solution (36), one should have taken $Z = k\left[x - \left(4k^2 + 16\epsilon a_1^{(1)} k^4\right) t\right]$ in the terms multiplied by ϵ, and $Z = k\left(x - 4k^2 t\right)$ in the terms multiplied by ϵ^2. However, the approximation properties for such a solution were found to be even worse than those for (36).

We also conclude, based on some features of the solitary wave solutions of the a-equation (not discussed here), that the solutions constructed via Kodama's transformation cannot (because of the k-dependence of their approximation properties) reflect some solution features intrinsic for the original physical system.

Some algebro-geometric origins of q-differential equations are examined.

1 Introduction

Many q-differential operators arise in the study of q-special functions, Casimir operators, quantum groups, and representation theory. There are also natural origins via quantum integrable systems and the quantization of classical integrable systems. The latter is often expressed via a q-hierarchy picture akin to the standard Hirota–Lax–Sato formulation and this has many canonical aspects. On the other hand one can produce a great number of q-differential operators by more or less ad hoc manipulation of noncommutative differential calculi or by variations of classical Lie group methods applied to quantum groups. We examine first the hierarchy picture briefly and notice that although the standard methods generalize quite readily the resulting KP or KdV equations for example seem to have an infinite number of terms whereas many "ad hoc" derivations from differential calculi or e.g. Maurer–Cartan arguments have only a finite number of terms and there is no clear way to determine if in fact such equations have any intrinsic meaning. We show that the standard derivation of KdV via vector fields on the unit circle and the smooth dual space of Lax operators can be extended to a q-situation using a q-Virasoro algebra and we produce a corresponding qKdV equation with an infinite number of terms; this seems to be a fairly canonical derivation and we suggest that it could be equivalent to the hierarchy qKdV equation (not yet proved). This approach to KdV via the unit circle with its attendant UrKdV–mKdV equations, Schwarzian derivatives, projective geometry, etc. has another connection to quantum mechanics (QM) via the beautiful equivalence principle of Faraggi–Matone and we use this as a motivational background (cf. [1]). In this connection we remark that in fact KP for example can already be considered as a Moyal quantization of dKP (dispersionless KP) and it is not clear just what role the qKP or qKdV equations can play in quantum mechanics; however for completeness we also indicate a few approaches to Moyal type integrable equations.

2 The equivalence principle

The equivalence principle (EP) of Faraggi–Matone (cf. refs. [1, 2]) is based on the idea that all physical systems can be connected by a coordinate transformation to the free situation with vanishing energy (i.e. all potentials are equivalent under coordinate transformations). This automatically leads to the quantum stationary Hamilton–Jacobi equation (QSHJE) which is a third-order nonlinear differential equation providing a trajectory representation of quantum mechanics (QM). The theory transcends in several respects the Bohm theory and in particular utilizes a Floydian time (cf. ref. [3]) leading to **(A1)** $\dot{q} = p/m_Q \neq p/m$ where **(A2)** $m_Q = m(1 - \partial_E Q)$ is the "quantum mass" and Q the "quantum potential". Thus the EP is reminscient of the Einstein equivalence of relativity theory. This latter served as a midwife to the birth of relativity but was somewhat inaccurate in its original form. It is better put as saying that all laws of physics

should be invariant under general coordinate transformations (cf. ref. [4]). This demands that not only the form but also the content of the equations be unchanged. More precisely the equations should be covariant and all absolute constants in the equations are to be left unchanged (e.g. c, $\hbar$, e, m and $\eta_{\mu\nu}$ = Minkowski tensor). Now for the EP, the classical picture with $S^{cl}(q, Q^0, t)$ the Hamilton principal function ($p = \partial S^{cl}/\partial q$) and P^0, Q^0 playing the role of initial conditions involves the classical HJ equation (CHJE) **(A3)** $H(q,p) = (\partial S^{cl}/\partial q), t) + (\partial S^{cl}/\partial t) = 0$. For time independent V one writes $S^{cl} = S_0^{cl}(q, Q^0) - Et$ and arrives at the classical stationary HJ equation (CSHJE) **(A4)** $(1/2m)(\partial S_0^{cl}/\partial q)^2 + \mathfrak{W} = 0$ where $\mathfrak{W} = V(q) - E$. In the Bohm theory one looked at Schrödinger equations **(A5)** $i\hbar\psi_t = -(\hbar^2/2m)\psi'' + V\psi$ with $\psi = \psi(q)\exp(-iEt/\hbar)$ and **(A6)** $\psi(q) = R(q\exp(i\hat{W}/\hbar)$ leading to

$$\left(\frac{1}{2m}\right)(\hat{W}')^2 + V - E - \frac{\hbar^2 R''}{2mR} = 0, \qquad (R^2\hat{W}')' = 0, \tag{1}$$

where **(A7)** $\hat{Q} = -\hbar^2 R''/2mR$ was called the quantum potential; this can be written in the Schwartzian form **(A8)** $\hat{Q} = (\hbar^2/4m)\{\hat{W}; q\}$ (via $R^2\hat{W}' = c$). Here **(A9)** $\{f; q\} = (f'''/f') - (3/2)(f''/f')^2$. Writing $\mathfrak{W} = V(q) - E$ as in **(A4)** we have the quantum stationary HJ equation (QSHJE) **(A10)** $(1/2m)(\partial\hat{W}'/\partial q)^2 + \mathfrak{W}(q) + \hat{Q}(q) = 0$ ($\equiv \mathfrak{W} = -(\hbar^2/4m)\{\exp(2iS_0/\hbar); q\}$). This was worked out in the Bohm school (without the Schwarzian connections) but **(A6)** is not appropriate for all situations; the Bohm theory is incomplete and can lead to incorrect predictions. The technique of Faraggi–Matone (FM) is completely general and with only the EP as guide one exploits the relations between Schwarzians, Legendre duality, and the geometry of a second-order differential operator $D_x^2 + V(x)$ (Möbius transformations play an important role here) to arrive at the QSHJE in the form

$$\frac{1}{2m}\left(\frac{\partial S_0^v(q^v)}{\partial q^v}\right)^2 + \mathfrak{W}(q^v) + \mathfrak{Q}^v(q^v) = 0, \tag{2}$$

where $v : q \to q^v$ represents an arbitrary locally invertible coordinate transformation. Note in this direction for example that the Schwarzian derivative of the the ratio of two linearly independent elements in $ker\,(D_x^2 + V(x))$ is twice $V(x)$. In particular given an arbitrary system with coordinate q and reduced action $S_0(q)$ the system with coordinate q^0 corresponding to $V - E = 0$ involves **(A11)** $\mathfrak{W}(q) = (q^0; q)$ where (q^0, q) is a cocycle term which has the form **(A12)** $(q^a; q^b) = -(\hbar^2/4m)\{q^a; q^b\}$. In fact it can be said that the essence of the EP is the cocycle condition **(A13)** $(q^a; q^c) = (\partial_{q^c} q^b)^2[(q^a; q^b) - (q^c; q^b)]$.

In addition FM developed a theory of (x, ψ) duality (cf. ref. [1]) which related the space coordinate and the wave function via a prepotential (free energy) in the form $\mathfrak{F} = (1/2)\psi\bar{\psi} + iX/\epsilon$ for example. A number of interesting philosophical points arise (e.g. the emergence of space from the wave function) and we connected this to various features of dispersionless KdV in refs. [5, 6] in a sort of extended WKB spirit. One should note here that although a form **(A6)** is not generally appropriate it is correct when one is dealing with two independent solutions of the Schrödinger equation ψ and $\bar{\psi}$ which are not proportional. In this context we utilized some interplay between various geometric properties of KdV which involve the Lax operator $L^2 = D_x^2 + V(x)$ and of course this is all related to Schwartzians, Virasoro algebras, and vector fields on S^1 (see e.g. refs. [7–10]. Thus the simple presence of the Schrödinger equation (SE) in QM automatically incorporates a host of geometrical properties of $D_x = d/dx$ and the circle S^1. In fact since the FM theory exhibits the fundamental nature of the SE via its geometrical properties connected to the QSHJE one could speculate about trivializing QM to a study of S^1 and ∂_x!

In any event KdV in its geometrical glory is important and we want to look at qKdV and qKP. A main theme here is to understand the relation of the qKdV hierarchy picture in terms of a geometrical origin of qKdV type equations. The hierarchy picture is described below. We also

give various derivations of qKdv and qKP type equations from various geometrical or quantum group points of view (most of which are not equivalent to the hierarchy pictures). However we do find a qKdV equation from a q-Virasoro context which could agree with the hierarchy picture (see Section 6). Even so it is not entirely obvious that the hierarchy picture is the only legitimate object of study – although the analytic approach of ref. [11] and the algebraic (oper) approach of ref. [12] do point in this direction.

3 KP and KDV hierarchies

For classical KP and KdV one has (cf. refs. [5, 6, 13, 14]

$$L = \partial + \sum_1^\infty u_{n+1}(t)\partial^{-n}, \qquad W = 1 + \sum_1^\infty w_n\partial^{-n}, \qquad L = W\partial W^{-1} \tag{3}$$

with **(A14)** $\psi = We^\xi = W(\lambda)e^\xi$; $\xi = \sum_1^\infty t_n\lambda^n$; $L\psi = -\lambda\psi$; $\partial_m\psi = B_m\psi = L_+^m\psi$ and **(A15)** $\partial_m L = [B_m, L]$; $\partial_n B_m - \partial_m B_n = [B_n, B_m]$; $\partial_n W = -(L_-^n)W$. Recall **(A16)** $\psi(t,\lambda) = \frac{X(\lambda)\tau}{\tau} = \frac{e^\xi\tau\left(t_j - \frac{1}{j\lambda^j}\right)}{\tau(t)} = \frac{e^\xi\tau_-}{\tau}$ where τ is the famous tau function with **(A17)** $u = \partial_x^2\log(\tau)$ with $u \sim u_2$ in 3. Typical forms for KP and KdV are **(A18)** $u_t - u_{xxx} + 6uu_x - 3\partial^{-1}u_{yy} = 0$ and $u_t - u_{xxx} + 6uu_x = 0$. For KdV one has $L_+^2 = L^2$ and the hierarchy picture is much simplified; we discuss this below in the context of qKdV.

4 *Q*-hierarchies

For qKP we go to refs. [11, 12, 14–23]; the hierarchy picture is straightforward but the resulting equations are much more complicated. Thus one writes e.g. **(A19)** $\partial_q f(x) = [f(qx) - f(x)]/(q-1)x$ and $Df(x) = f(qx)$. Then in the hierarchy constructions x and $t = t_1$ are both used in the first variable position with

$$\tau_q(x,t) = \tau(t_i + c(x)_i), \qquad c(x) = \left(\frac{(1-q)x}{1-q}, \ldots, \frac{(1-q)^n x^n}{n(1-q^n)}, \ldots\right), \tag{4}$$

where τ is an ordinary tau function for KP. One takes then ($\partial_1 \sim \partial/\partial t_1, \ldots, \partial_n \sim \partial/\partial t_n$)

$$L_q = \partial_q + \sum_0^\infty a_n(t)\partial_q^{-n}, \qquad \partial_n L_q = [(L_q^n)_+, L_q] = [B_n^q, L_q] \tag{5}$$

(note $a_0 \neq 0$ appears here and $u \sim a_1$). Further ($\xi = \sum_1^\infty t_k\lambda^k$)

$$\psi_q = \frac{\tau_q(x, t - [\lambda^{-1}])}{\tau_q(x,t)} e_q(x\lambda)\exp(\xi), \qquad (q;q)_k = (1-q)\cdots(1-q^k), \tag{6}$$

$$\exp_q(x) = \sum_1^\infty \frac{(1-q)^k x^k}{(q;q)_k} = \exp\left(\sum_1^\infty \frac{1-q)^k x^k}{k(1-q^k)}\right), \qquad \partial_q e_q(x\lambda) = \lambda e_q(x),$$

where $[\lambda^{-1}] = (1/n\lambda^n)$. Note also **(A20)** $\psi_q = W_q e_q(x\lambda)e^\xi$; $L_q\psi_q = \lambda\psi_q$ with

$$L_q = W_q\partial_q W_q^{-1}, \qquad W_q = 1 + \sum_1^\infty \tilde{w}_j\partial_q^{-j}, \qquad \partial_j W_q = -(L_q^j)_- W_q. \tag{7}$$

Next note $e_q(x\lambda)^{-1} = e_{1/q}(-x\lambda)$ and the adjoint wave function ψ_q^* is determined via

$$\psi_q^* = (W^*)^{-1}_{x/q} \exp_{1/q}(-x\lambda)e^{\xi}, \qquad L^*_{x/q}\psi_q^* = \lambda\psi_q^*,$$
$$\psi_q^* = \frac{\tau_q(x, t + [\lambda^{-1}])}{\tau_q(x,t)} \exp_{1/q}(-x\lambda)e^{-\xi}, \tag{8}$$

where $V = \sum v_i\partial_q^i \sim V^* = \sum(\partial_q^*)^i v_i$ with $\partial_q^* = -q^{-1}\partial_{1/q}$ and $V_{x/q} \sim \sum v_i(x/q)q^i\partial_q^i$. Recall also the Schur polynomials

$$\sum p_n(t)\lambda^n = \exp(\xi(t,\lambda)), \qquad \sum \tilde{p}_n(x,t)\lambda^n = \exp_q(x\lambda)e^{\xi(t,\lambda)},$$
$$\tilde{p}_k(x,t) = p_k(t + c(x)). \tag{9}$$

Next the classical Hirota bilinear identity is

$$\oint \psi^*(t,\lambda)\psi(t',\lambda)d\lambda = 0 \quad \Rightarrow \quad \oint \tau(t + y + [\lambda^{-1}])\tau(t - y - [\lambda^{-1}])e^{-2\sum y_i\lambda^i} = 0 \tag{10}$$

and this leads to classical Hirota equations **(A21)** $\partial_1\partial_n\tau\cdot\tau = 2p_{n+1}(\tilde{\partial})\tau\cdot\tau$ (Hirota notation – also $\tilde{\partial} = (\partial_1, (1/2)\partial_2, \ldots)$). One can produce analogous formulas in q-theory but their usefulness is limited and not even clear (cf. ref. [14] for an extensive discussion). The problem lies in the fact that $u = \partial^2 \log\tau$ does not generalize but instead

$$u = -(q-1)x\partial_q\left(\frac{p_2(\tilde{\partial})\tau_q}{\tau_q}\right) + \frac{\partial_q\tau_q}{\tau_q}(q-1)x\partial_q\left(\frac{\partial_1\tau_q}{\tau_1}\right) + \partial_q\left(\frac{\partial_q\tau_q}{\tau_q}\right). \tag{11}$$

The classical Hirota equations are compatible with and lead to formulas involving $\log\tau$ (and hence u) but in the q-situation (11) makes this impossible. In fact I have never seen a qKP equation analogous to **(A18)** for example.

The problems are more easily seen with qKdV and there one has (recall $Df(x) = f(qx)$)

$$L_q^2 = \partial_q^2 + (q-1)xu\partial_q + u, \qquad u = \partial_q\partial_1\log[\tau_q(x,t)D\tau_q(x,t)],$$
$$L_q = \partial_q + s_0 + s_1\partial_q^{-1} + \cdots. \tag{12}$$

Considerable calculation leads to ($u_1 = (q-1)xu$)

$$s_0 = (q-1)x\partial_1\partial_q\log\tau_q, \qquad \partial_t u = (\partial_q^3 u) + w_2(\partial_q^2 u) + w_1(\partial_q u) - [(\partial_q^2 w_0) + u_1(\partial_q w_0)], \tag{13}$$
$$w_2 = D^2 s_0 + u_1 = D^2 s_0 + Ds_0 + s_0, \tag{14}$$
$$w_1 = (q+1)(D\partial_q s_0) + \tau^2 s_1 + [(Ds_0) + s_0](Ds_0) + u,$$
$$w_0 = \partial_q^2 s_0 + (q+1)(D\partial_q s_1) + u_1\partial_q s_0 + u_1(Ds_1) + us_0 + D^2 s_2$$

and the determination of the s_i requires infinite series calculations based on formulas like

$$s_1 + Ds_1 = u - \partial_q s_0 - s_0^2 = f \quad \Rightarrow \quad s_1(x) = \sum_0^\infty (-1)^n f(q^n x). \tag{15}$$

Similarly **(A22)** $Ds_2 + s_2 = -\partial_q s_1 - s_0 s_1 - s_1 D^{-1} s_0$, etc. This seems to suggest that an explicit form of qKdV (as in **(A18)**) arising in the hierarchy picture with coefficients specified in terms of u (or s_0) will involve an infinite number of terms.

5 Origins of Q-equations

5.1 Linear equations

In refs. [14–16] we sketched a number of sources for linear q-differential equations in various contexts (see the references there for details and cf. also refs. [24, 25]). This includes many relations involving q-special functions, Casimir operators, quantum groups, and representation theory with linear q-differential equations arising naturally. A good source of general information with Lie theoretic background is refs. [26, 27]. There is also a development involving special functions and q-special functions where tau functions arise as generating functions for matrix elements in general group representations (cf. ref. [15] and references there).

Remark 1. The development in ref. [26] for example emphasizes the ideas of intertwining and group invariant differential operators in a general Lie theoretic context with representations involving Verma modules (cf. also ref. [27] and references there). One arrives e.g. at a Maxwell hierarchy and its quantum group version in the context of a particular q-Minkowski space-time. The spirit is that of QG symmetries described via invariant q-differential operators and here the equations are also q-conformally invariant. Other work involving Dirac equations is described in ref. [15] for example and the differential operators involved seem to be primarily linear. However the treatment in ref. [27] provides interesting nonlinear differential operators in the context of multilinear intertwining differential operators. Bilinear and trilinear formulas for example are written out for $\mathfrak{sl}(2)$ and there is an interesting connection to KdV. Thus let G be a Lie group with representations T, T' in spaces C, C'. An intertwining operator $\mathfrak{I}$ is a continuous linear map **(A23)** $\mathfrak{I} : C \to C' : f \to j$ such that **(A24)** $\mathfrak{I} \circ T(g) = T'(g) \circ \mathfrak{I}$. The equation **(A25)** $\mathfrak{I}f = j$ is then a G-invariant equation. Omitting details one defines multilinear intertwining differential operators via

$$ {}_k\mathfrak{I} : f \otimes \cdots \otimes f \to j;\ {}_k\mathfrak{I} \circ T(g) \otimes \cdots \otimes T(g) = T'(g) \circ {}_k\mathfrak{I} \tag{16} $$

and arrives at generalized Schwarzians **(A26)** $\widetilde{Sch}_n(\phi) = [1/(\phi')^2]_2\mathfrak{I}^0_{n\alpha}(\phi)$. Recalling that the KdV equation can be written in the Krichever–Novikov form **(A27)** $\partial_t f + \widetilde{Sch}_4(f)f' = 0$ (note $\widetilde{Sch}_4(f) = S(f)$ is the Schwarzian derivative) one can pass to the standard KdV form **(A28)** $\partial_t u + u''' - 6uu' = 0$ where the substitution $u = -(1/2)\widetilde{Sch}_4(f)$ is used. It is conjectured in ref. [27] that the equations **(A29)** $\partial_t f + \widetilde{Sch}_n(f)f' = 0$ ($n \in 2\mathbb{N}+2$) are integrable, and if so they should coincide with the KdV hierarchy. One expects that a similar analysis in the q-context would be of great interest in understanding qKdV.

5.2 Differential calculi

When we come to nonlinear equations such as KP or KdV there are a number of classical derivations of intrinsic geometrical or algebraic interest which should morally have a q-version. Moreover one would expect the q-versions to bear some natural or canonical relation to the hierarchy version described earlier. In refs. [14–16] we examined some such derivations but without being able to establish a clear connection to the hierarchy picture. The constructions however seem interesting enough and well modeled on meaningful classical situations so some further study is indicated. First in a somewhat experimental manner consider a differential calculus approach following refs. [14–16, 28]. Thus

Example 1. Consider a calculus based on **(A)** $dt^2 = dx^2 = dxdt + dtdx = 0$ **(B)** $[dt, t] = [dx, t] = [dt, x] = 0$ and $[dx, x] = \eta dt$. Assuming the Leibnitz rule $d(fg) = (df)g + f(dg)$ for functions and $d^2 = 0$ one obtains **(A30)** $df = f_x dx + (f_t + (1/2)\eta f_{xx})dt$. For a connection $A = wdt + udx$ the zero curvature condition $F = dA + A^2 = 0$ leads to **(A31)** $(u_t - w_x + (\eta/2)u_{xx} + \eta u u_x = 0$ which for $w_x = 0$ is a form of Burger's equation.

Example 2. Next consider **(A)** $[dt,t]=[dx,t]=[dt,x]=[dy,t]=[dt,y]=[dy,y]=0$ with **(B)** $[dx,x]=2bdy$ and $[dx,y]=[dy,x]=3adt$. Further **(C)** $dt^2=dy^2=dtdx+dxdt=dydt+dtdy=dydx+dxdy=0$. Then **(A32)** $df=f_xdx+(f_y+bf_{xx})dy+(f_t+3af_{xy}+abf_{xxx}dt)$. For $A=vdx+wdt+udy$ one finds that $dA+A^2=F=0$ implies

$$u_x=v_y+bv_{xx}+2bvv_x,\qquad w_x=3av_{xy}+abv_{xxx}+3auv_x+3av(v_y+bv_{xx}),\tag{17}$$
$$w_x+bw_{xx}=u_t+3au_{xy}+abu_{xxx}+3auu_x-v[2bw_x-3a(u_y+bu_{xx})].$$

Taking e.g. $w_x=(3a/2b)u_y+(3a/2)u_{xx}$ in the last equation to decouple one arrives at **(A33)** $\partial_x(u_t-(ab/2)u_{xxx}+3auu_x)=(3a/2b)u_{yy}$; for suitable a, b this is KP. If the equation is independent of y we obtain a version of KdV.

It is surprisingly difficult to convert these examples into meaningful q-calculus equations and in that spirit for guidance we were motivated to develop many formulas concerning qKP, qKdV, etc. One has e.g. a first-order differential calculus (FODC) Γ_+ from ref. [25] on a quantum plane or Manin plane (cf. also ref. [15]); this is based on $xp=qpx$ with standard formulas as in ref. [25]. In this FODC the partial derivatives ∂_i of Γ_+ act on $\mathfrak{A}=$ formal power series with x, p ordering, via ($\partial_p x^n=q^nx^n\partial_p$ and $\partial_x p^n=q^np^n\partial_x$)

$$\partial_x(f(x)h(p))=(D^x_{q^2}f(x))h(p),\qquad \partial_p(f(x)h(p))=(T_qf(x))(D^p_{q^2}h(p)),\tag{18}$$

$$\partial_x(x^n)=D_{q^2}x^n=[[n]]_{q^2}x^{n-1},\qquad [[n]]_{q^2}=\frac{q^{2n}-1}{q^2-1},\qquad \partial_p p^n=[[n]]_{q^2}p^{n-1}.\tag{19}$$

Example 3. The q-plane itself doesn't seem immediately fruitful here so consider the generalized q-plane with an algebra generated by x, y, x^{-1}, y^{-1} where $xy=qyx$, $xdx=qdxx$, $ydx=q^{-1}dxy$, $xdy=qdyx$, and $ydy=q^{-1}dyy$. Also from $qdyx=dxy$ we have $qdydx=dxdy$ and a little calculation yields **(A34)** $dx^n=[(1-q^{-n})/(1-q^{-1})]x^{n-1}dx$ with $dy^m=[(1-q^m)/(1-q)]y^{m-1}dy$. Working from $f=\sum a_{nm}x^ny^m$ one obtains then (note $dxy^m=q^my^mdx$)

$$df=D_yD^x_{q^{-1}}fdx+D^y_qfdy.\tag{20}$$

Set then $A=wdy+udx$ with $dA=D_yD^x_{q^{-1}}wdxdy+D^y_qudydx$ and, noting that $dyx^n=q^{-n}x^ndy$, $dyy^m=q^my^mdy$, and $dxy^m=q^my^mdx$ with $dxx^n=q^{-n}x^ndx$ one gets $dyw=D_x^{-1}D_ywdy$ and $dxu=D_x^{-1}D_yudx$ leading to $A^2=wD_x^{-1}D_yudydx+uD_x^{-1}D_ywdxdy$; and

$$dA+A^2=0=qD_yD^x_{q^{-1}}w+D^y_qu+wD_x^{-1}D_yu+quD_x^{-1}D_yw.\tag{21}$$

Setting then e.g. $qw=D_y^{-1}D^x_{q^{-1}}u$ one gets

$$D^y_qu+(D^x_{q^{-1}})^2u+q^{-1}(D_x^{-1}D_yu)(D_y^{-1}D^x_{q^{-1}}u)+uD_x^{-1}D^x_{q^{-1}}u=0.\tag{22}$$

For $q\to 1$ we have **(A35)** $u_y+u_{xx}+2uu_x=0$ so this appears to be an exact q-form of Burger's equation.

Example 4. We will try now a somewhat different approach. First we take q-derivatives only in x, as in the case of qKP for example and we know from Example 2 that **(A32)** leads to interesting consequences so begin with an assumption ($f_y=\partial f/\partial y$, etc.)

$$df=D^x_qfdx+\left(f_y+b(D^x_q)^2f\right)dy+\left(f_t+3a\partial_yD^x_qf+ab(D^x_q)^3f\right)dt.\tag{23}$$

Then we can determine what elementary commutation relations between the variables are consistent with (23). This is rather ad hoc but we stipulate x, y, t ordering and then there are relations

$$dxx=qxdx+b[2]_qdy,\qquad dyx=q^2xdy+a[3]_qdt,$$
$$dtx=q^3xdt,\qquad dxy=ydx+3adt\tag{24}$$

along with

$$[dt,y]=[dy,y]=[dy,t]=[dx,t]=[dt,t]=[dx,y]=0 \tag{25}$$

which are determined by (23). The underlying structure for x,y,t is not visible from (23) but (24)–(25) do lead to (23) and whatever zero curvature equations subsequently arise (see ref. [16] for details). Returning now to (23) it remains to check now the zero curvature equation arising in the spirit of Example 2 (some extra factors and terms will arise via noncommutativity). Thus assume first $dx^2=dy^2=dt^2=0$ and take $A=vdx+wdt+udy$; after some computation modeled on Example 2 one arrives at a rather clumsy q-version of KP. For y independent u we obtain

$$\begin{aligned} &u_t+ab(D_q^x)^3u-\frac{[3]_qab}{[2]_q}D_q^xD_x(D_q^x)^2u+[3]_qauD_x^2D_q^xu\\ &\quad=\frac{[3]_qa}{[2]_qb}\left(D_xD_q^xuD_x^3u-uD_x^3D_q^xu\right) \end{aligned} \tag{26}$$

which is a quantum KdV type equation.

5.3 Geometry

We indicate two "geometrical" contexts in a classical vein and subsequently give "quantum" versions of these.

Example 5. One can devise a procedure directly from ref. [29]. Thus look at $SL(2,\mathbb{R})$ with matrices **(A36)** $X=\begin{pmatrix} a & b\\ c & d\end{pmatrix}$, $ad-bc=1$. The right invariant Maurer–Cartan (MC) form is **(A37)** $\omega=dXX^{-1}=(w_j^i)$ $(i,j=1,2)$ where $\omega_1^1+\omega_2^2=0$. The structure equation of $SL(2,\mathbb{R})$ or MC equation is **(A38)** $d\omega=\omega\wedge\omega$ or explicitly **(A39)** $d\omega_1^1=\omega_1^2\wedge\omega_2^1$; $d\omega_1^2=2\omega_1^1\wedge\omega_1^2$; $d\omega_2^1=2\omega_2^1\wedge\omega_1^1$. Now let U be a neighborhood in the (x,t) plane and consider a smooth map $f:U\to SL(2,\mathbb{R})$. The pullback of the MC form can be written as **(A40)** $\omega_1^1\sim\eta dx+Adt$; $\omega_1^2\sim Qdx+Bdt$; $\omega_2^1\sim rdx+Cdt$ with coefficient functions of x, t. The equations **(A39)** become **(A41)** (i) $-\eta_t+A_x-QC+rB=0$, (ii) $-Q_t+B_x-2\eta B+2QA=0$, and (iii) $-r_t+C_x-2rA+2\eta C=0$. Take $r=1$ with η independent of (x,t) and set $Q=u(x,t)$. Then from (i) and (iii) one gets **(A42)** $A=\eta C+\frac{1}{2}C_x$; $B=uC-\eta C_x-\frac{1}{2}C_{xx}$. Putting this in the (ii) above yields $u_t=K(u)$ where **(A43)** $K(u)=u_xC+2uC_x+2\eta^2C_x-\frac{1}{2}C_{xxx}$. In the special case $C=\eta^2-(1/2)u$ one gets the KdV equation **(A44)** $u_t=\frac{1}{4}u_{xxx}-\frac{3}{2}uu_x$.

Example 6. Following ref. [30], let $\mathrm{Vec}\,(S^1)$ denote the Lie algebra of smooth vector fields on S^1 and then the Virasoro algebra is $\mathrm{Vir}=\mathrm{Vec}(S^1)\oplus\mathbb{R}=\mathfrak{W}\oplus\mathbb{R}$ with (note the minus sign convention involving $f'g-fg'$)

$$[(f(x)\partial_x,a),(g(x)\partial_x,b)]=\left((f'g-fg')\partial_x,\int_{S^1}f'g''dx\right) \tag{27}$$

($\mathfrak{W}\sim$ Witt algebra). Here $\int_{S^1}f'g''dx$ is called the Gelfand–Fuks cocycle, where a cocycle on a Lie algebra $\mathfrak{g}$ is a bilinear skew symmetric form $c(\cdot,\cdot)$ satisfying **(A45)** $\sum c([f,g],h)=0$ over cyclic permutations of f, g, h. This means that $\hat{\mathfrak{g}}=\mathfrak{g}\oplus\mathbb{R}$ (central extension) with commutator $[(f,a),(g,b)]=([f,g],c(f,g))$ satisfies the Jacobi identity of a Lie algebra. Now the Euler equation corresponding to geodesic flow is a 1-parameter family of KdV equations. To see how this arises consider **(A46)** $\mathrm{Vir}^*=\{(u(x)dx^2,c);\ u \text{ smooth on } S^1 \text{ and } c\in\mathbb{R}\}$. Then **(A47)** $\langle(v(x)\partial_x,a),(u(x)dx^2,c)\rangle=\int_{S^1}v(x)u(x)dx+ac$. The coadjoint action of $(f\partial_x,a)\in\mathrm{Vir}$ on $(udx^2,c)\in\mathrm{Vir}^*$ is $(\mathrm{ad}_v^*:\mathfrak{g}^*\to\mathfrak{g}^*,\ \mathrm{ad}_v^*w(u)=w(ad_vu))$ **(A48)** $\mathrm{ad}^*_{(f\partial_x,a)}(udx^2,c)=$

$(2f'u + fu' + cf''')dx^2, 0)$ which arises from the identity **(A49)** $\langle[(f\partial_x, a), (g\partial_x, b)], (udx^2, c)\rangle = \langle(g\partial_x, b), \mathrm{ad}^*_{(f\partial_x,a)}(udx^2, c)\rangle$. Now for S^1 there are no boundary terms in integration (for single valued functions) so, integrating by parts,

$$\int_{S^1} g(2f'u + fu' + cf''')dx = \int_{S^1} [u(gf' - fg') + cf'g'']dx. \tag{28}$$

Now a function H on $\mathfrak{g} = \mathrm{Vir}$ determines a tautological inertia operator $A : \mathrm{Vir} \to \mathrm{Vir}^* : (u\partial_x, c) \to (udx^2, c)$ and hence a quadratic Hamiltonian on Vir^* via

$$H(udx^2, c) = \frac{1}{2}\langle(u\partial_x, c), (udx^2, c)\rangle = \frac{1}{2}\langle(u\partial_x, c), A(u\partial_x, c)\rangle. \tag{29}$$

Following ref. [30] the corresponding Euler equation is $\dot{m} = -\mathrm{ad}^*_{A^{-1}m}m$ $(m \in \hat{\mathfrak{g}})$ which here takes the form **(A50)** $\partial_t(udx^2, c) = -\mathrm{ad}^*_{A^{-1}(udx^2,c)}(udx^2, c)$. Using **(A51)** $(f\partial_x, a) = A^{-1}(udx^2, c) = (u\partial_x, c)$ this becomes an equation **(A52)** $\partial_t u = -2u'u - uu' - cu''' = -3uu' - cu'''$ where c is independent of time.

6 Q-versions

6.1 Q-Virasoro

We recall first from refs. [16, 31] the following information regarding q-Virasoro constructions. Thus work on S^1 with $(q \neq 0, \pm 1)$

$$\partial_q z = \frac{q^m z^m - q^{-m} z^m}{(q - q^{-1})z} = z^{m-1}[m], \qquad [m] = \frac{q^m - q^{-m}}{q - q^{-1}}. \tag{30}$$

We adapt the formalism of ref. [31] as follows. Let $D_n = -z^{n+1}\partial$ with $\partial : z^m \to q^m[m]z^{m-1}$ so $\partial \sim \partial_q\tau$ where $\tau f(z) = f(qz)$. Generally we will think of $z = e^{i\theta} \in S^1$ so $(1/2\pi i)\int_{S^1} z^n dz = (1/2\pi)\int z^{n+1}d\theta = \delta_{(-1,0)}$ which will be written as **(A52)** $\int z^n = \delta_{(-1,0)}$. Write also **(A53)** $\ell_n \sim D_n = -z^{n+1}\partial_q\tau$ and it is known that q-brackets are needed now where **(A54)** $[\ell_m, \ell_n]_q = q^{m-n}\ell_m\ell_n - q^{n-m}\ell_n\ell_m = [m-n]\ell_{m+n}$. For a central term in a putative Vir_q one wants (cf. refs. [16, 31]) a formula **(A55)** $c[m+1][m][m-1]\delta_{m+m,0}$ (see below for an optimal term). First we want to formulate the q-bracket in terms of vector fields as follows (the central term will be added later). This can be done as a direct calculation using the basic definition of ∂ above (cf. also (37) below). Thus

$$[z^n\partial, z^m\partial]_q \sim q^{n-m}z^n\partial(z^m\partial) - q^{m-n}z^m\partial(z^n\partial) = [n-m](-z^{m+n-1}\partial). \tag{31}$$

Let now $v \sim \sum a_n z^n$ and $w \sim \sum b_m z^m$; then we define a bracket in $Vec(S^1)$ via **(A56)** $[v\partial, w\partial]_q = -\sum a_n b_m [n-m]z^{m+n-1}\partial$. We defined a bracket of vector fields in ref. [16] so that from **(A56)** there resulted a correspondence **(A57)** $v'w - vw' \sim -[v\partial_x, w\partial_x] \sim -[v\partial, w\partial]_q = -\{(\tau v)(\partial_q w) - (\tau w)(\partial_q v)\}\tau$. This dangling τ creates some complications and is removed below.

Remark 2. In ref. [31] one defines the q-analogue of the enveloping algebra of the Witt algebra $\mathfrak{W}$ as the associative algebra $\mathfrak{U}_q(\mathfrak{W})$ having generators ℓ_m $(m \in \mathbb{Z})$ and relations **(A54)**. The q-deformed Virasoro algebra is defined as the associative algebra $\mathfrak{U}_q(\mathrm{Vir})$ having generators ℓ_m $(m \in \mathbb{Z})$ and relations $(q \neq$ root of unity)

$$q^{m-n}\ell_m\ell_n - q^{n-m}\ell_n\ell_m = [m-n]\ell_{m+n} + \delta_{m+n,0}\frac{[m+1][m][m-1]}{[2][3]\langle m\rangle}\hat{c}, \tag{32}$$

where $\langle m\rangle = q^m + q^{-m}$ and $\hat{c}\ell_m = q^{2m}\ell_m\hat{c}$ (thus $\hat{c}$ is an operator which we examine below and we refer to refs. [16, 31] for the central term). Then $\mathfrak{U}_q(\mathrm{Vir}) \sim \mathrm{Vir}_q$ is a $\mathbb{Z}$ graded algebra

with $\deg(\ell_m) = m$ and $\deg(\hat{c}) = 0$. One also introduces in ref. [31] a larger algebra $\mathfrak{U}(V_q) =$ associative algebra generated by $J^{\pm 1}$, $\hat{c}$, d_m $(m \in \mathbb{Z})$ with relations

$$JJ^{-1} = J^{-1}J = 1, \qquad Jd_mJ^{-1} = q^m d_m, \qquad \hat{c}J = J\hat{c}, \qquad \hat{c}d_m = q^m d_m\hat{c}, \tag{33}$$
$$q^m d_m d_n J - q^n d_n d_m J = [m-n]d_{m+n} + \delta_{m+n,0}\frac{[m+1][m][m-1]}{[2][3]\langle m\rangle}\hat{c}.$$

The subalgebra of $\mathfrak{U}(V_q)$ generated by $\ell'_m = d_m J$ and $\hat{c}' = \hat{c}J$ $(m \in \mathbb{Z})$ is the same as $\mathfrak{U}_q(\mathrm{Vir})$. It is stated in ref. [31] that V_q is the universal quantum central extension of $\mathfrak{W}_q$ and thus (33) is better adapted for optimal algebraic and geometric meaning; it is this aspect which we emphasize below.

Now we mimic the framework of Example 6 and it is interesting to note that an ordinary integral $\int_{S^1}$ will suffice. One does not need a Jackson type integral in order to deal with integration by parts. Thus we observe that **(A58)** $\int_{S^1} f = \int \sum f_n z^n = f_{-1}$; $\int \partial_q f = (q - q^{-1})^{-1}(f_0 - f_0) = 0$. Since $\partial_q(fh) = (\tau f)(\partial_q h) + (\partial_q f)(\tau^{-1}h)$ we have an integration by parts formula

$$\int (\tau f)(\partial_q h) = -\int (\partial_q f)(\tau^{-1}h) \Rightarrow \int f\partial_q(\tau h) = -\int \partial_q(\tau^{-1}f)h. \tag{34}$$

This can be written as (recall $\partial \sim \partial_q\tau$) **(A59)** $\int f\partial h = -\int h\hat{\partial}f$ for $\hat{\partial} = \partial_q\tau^{-1}$. Now we think of $\mathfrak{U}_q(\mathrm{Vir})$ with elements $(f\partial, a)$ satisfying **(A60)** $[(f\partial, a), (g\partial, b)] = (-[f\partial, g\partial]_q\partial, \psi(f\partial, g\partial))$. The central term could be defined tentatively via e.g. **(A61)** $\int(\tau\partial^3 f)(\tau g)\hat{c} = \psi(f\partial, g\partial)$ (where one notes that **(A62)** $\psi(f\partial, g\partial) = q^{-1}\int g\partial^3 f\hat{c}$). We will want to put the central operator $\hat{c}$ into the integral, acting on f, and will see below that $\hat{c} \sim \tau^2$ for example and $\tau^2 F(z) = F(q^2 z)\tau^2$ so it eventually automatically passes to the right in our qKdV type equations. Hence for the moment think of $\hat{c} = \tau^2$ put into **(A61)** via e.g. $\tau\partial^3\tau^{-2}\hat{c}f \equiv \tau\partial^3 f$ and ignored at the end except when exhibiting formulas like (32) on generators (see also remarks below).

We recall now from ref. [31] (second paper)

$$[d_m, d_n] = Jd_mJ^{-1}d_nJ - Jd_nJ^{-1}d_mJ = q^{-n}Jd_md_n - q^{-m}Jd_nd_m. \tag{35}$$

Further $\hat{c}d_m = q^m d_m\hat{c}$ suggests $\hat{c} = \tau$ here and d_m is being used as $\ell_m\tau^{-1}$. Dropping the minus sign momentarily, from $\ell_m = z^{m+1}\partial_q\tau$ we get then **(A63)** $d_m = z^{m+1}\partial_q$. Then, using **(A64)** $\partial_q\tau = q\tau\partial_q$, one obtains $\tau d_m = \tau(z^{m+1}\partial_q) = q^m z^{m+1}\partial_q\tau$ and $\tau^{-1}d_m = q^{-m}d_m\tau^{-1}$. In addition $Jd_mJ^{-1} = q^m d_m$ corresponds to $Jd_m = q^m d_m J$ so we identify $J = \tau$. Writing $\ell_m = d_m J = d_m\tau$ we can also easily see that the brackets $[d_m, d_n]$ above are exactly the q-brackets **(A65)** $[\ell_m, \ell_n]_q = q^m\ell_m\ell_n - q^n\ell_n\ell_m$.

Now in ref. [31] (second paper) a Jacobi type identity is used involving an operator $\sigma(x) = (1/2)(\tau + \tau^{-1})(x)$ for $x \in \oplus\mathbb{C}d_n$. This seems to be better phrased in terms of an operator **(A66)** $\Gamma(d_p) = \langle p\rangle d_p$ which avoids the need to carry τ around to other terms. Then we can check that the rule in (33) rewritten as **(A67)** $[d_m, d_n] = [m-n]d_{m+n} + \gamma_m\delta_{m+n,0}\hat{c}$ will yield

$$[[d_m, d_n], \Gamma(d_p)] + [[d_n, d_p], \Gamma(d_m)] + [[d_p, d_m], \Gamma(d_n)] = \Xi_{m,n,p} = 0. \tag{36}$$

This is based on two identities; one is **(A68)** $[m-n][m+n-p]\langle p\rangle + [n-p][n+p-m]\langle m\rangle + [p-m][p+m-n]\langle n\rangle = 0$ and the second is

$$[p+1][p][p-1][m-n] + [m+1][m][m-1][n-p] + [n+1][n][n-1][p-m] = 0 \qquad (m+n+p=0). \tag{37}$$

The proofs are essentially straightforward (cf. ref. [32] for details). Thus V_q will be a genuine central extension of $\mathfrak{W}_q$, with a reasonable Jacobi identity (36).

Remark 3. Now in 31–**(A57)** we recall $\ell_m \sim -z^{m+1}\partial = -z^{m+1}\partial_q\tau$ and a d_m formulation would drop the τ. Thus work with ∂_q instead of $\partial = \partial_q\tau$ with **(A69)** $\partial_q z^{p+1} = q^{p+1}z^{p+1}\partial_q + [p+1]z^p\tau^{-1}$ based on $\partial_q f = (\tau f)\partial_q + (\partial_q f)\tau^{-1}$. Then

$$\begin{aligned}[d_m, d_n] &= [z^{m+1}\partial_q, z^{n+1}\partial_q] \\ &= q^m d_m d_n\tau - q^n d_n d_m\tau = [n-m]z^{n+m+1}\partial_q = [m-n]d_{m+n}. \end{aligned} \tag{38}$$

In this context the $\delta_{m+n,0}$ term does not arise. Note here $\tau^{-1}\partial_q = q\partial_q\tau^{-1}$ and **(A70)** $q^{m+1}[n+1] - q^{n+1}[m+1] = [n-m]$. Let now $v \sim \sum v_{n+1}z^{n+1}$ and $w = \sum w_{m+1}z^{m+1}$; then

$$[v\partial_q, w\partial_q] = [\sum v_{n+1}d_n, \sum w_{m+1}d_m] = \sum v_{n+1}w_{m+1}[n-m]z^{n+m+1}\partial_q. \tag{39}$$

Going back to (38) this corresponds then to **(A71)** $[v\partial_q, w\partial_q] = [(\tau v)(\partial_q w) - (\tau w)(\partial_q v)]\partial_q$ and this replaces **(A57)**.

Now we build in a cocycle term by using (33) in (38); a term **(A72)** $[z^{m+1}\partial_q, z^{n+1}\partial_q] = [d_m, d_n] = [m-n]d_{m+n} + \gamma_m\delta_{m+n,0}\tau$ arises. For $[v\partial_q, w\partial_q]$ we get then an additional term

$$\sum v_{n+1}w_{m+1}\gamma_n\delta_{m+n,0}\tau = \sum v_{n+1}w_{-n+1}\frac{[n+1][n][n-1]\tau}{\langle n\rangle[2][3]}. \tag{40}$$

Then for $a = 1/[2][3]$ and $(\tau + \tau^{-1})z^n = (q^n + q^{-n})z^n = \langle n\rangle z^n$ define

$$a\int w(\partial_q^2(\tau+\tau^{-1})^{-1}(\partial_q v)) = \sum v_{n+1}w_{-n+1}\gamma_n = \phi(v\partial_q, w\partial_q). \tag{41}$$

One checks that ϕ is antisymmetric and satisfies the q-cocycle condition

$$\phi([v\partial_q, w\partial_q], \Gamma(u\partial_q)) + \phi([w\partial_q, u\partial_q], \Gamma(v\partial_q)) + \phi([u\partial_q, v\partial_q], \Gamma(w\partial_q)) = 0. \tag{42}$$

Consequently (cf. ref. [32] for details).

Theorem 1. *The term $\phi(v\partial_a, w\partial_q)$ in (41) is a q-cocycle and following the constructions in ref.* [16] *one has a possibly canonical qKdV equation in the form* ($a = 1/[2][3]$)

$$u_t + c'\partial_q^2(\tau+\tau^{-1})^{-1}\partial_q u + \partial_q(u\tau u) + \tau^{-1}u\partial_q\tau^{-1}u. \tag{43}$$

Proof. We modify slightly the constructions in ref. [16] and write

$$\begin{aligned} &q\langle[f\partial_q, a), (g\partial_q, b)], (u, c)\rangle \\ &\quad = -q\int[(\tau f)(\partial_q g) - (\tau f)(\partial_q f)]u + caq\int g\partial_q^2(\tau+\tau^{-1})^{-1}\partial_q^2 f. \end{aligned} \tag{44}$$

We note from ref. [16] that **(A73)** $q\int fg = \int\tau^{-1}f\tau^{-1}g$ and $\int\partial_q f = 0$ while via **(A74)** $\partial_q(gfu) = \partial_q f\tau^{-1}(fu) + (\tau g)\partial_q(fu)$ (via $\partial_q(ab) = (\tau a)\partial_q b + (\partial_a)\tau^{-1}b$). Then **(A75)** $\int g[\tau^{-1}\times \partial_q(\tau u\tau^2 f) + \tau^{-1}(u\partial_q f) + aqc\partial_q^2(\tau+\tau^{-1})^{-1}\partial_q f]$ follows from (44). Putting $f = u$ we obtain the Euler equation as in ref. [16], namely **(A76)** $qu_t = -qca\partial_q^2(\tau+\tau^{-1})^{-1}\partial_q u - \tau^{-1}\partial_q(\tau u\tau^2 u) - \tau^{-1}(u\partial_q u)$. Using also $\tau^{-1}\partial_q = q\partial_q\tau^{-1}$ we obtain (43) with $c' = ac$. ■

Remark 4. In view of the expression **(A77)** $(\tau+\tau^{-1})^{-1} \sim \tau\sum(-1)^n\tau^{2n}$ the equation (43) involves an infinite number of terms (much as are indicated for qKdV in the hierarchy picture in ref. [16]. Since we now have a derivation with all of the classical algebraic and geometrical structure duplicated it seems that (43) could be a good candidate for a canonical form.

Remark 5. The Maurer–Cartan (MC) formulas were indicated in Example 5 and a version of this in a q-plane context appears in ref. [25]. A version of this can also be developed directly from the discussion of duality (cf. ref. [16] for details). A more interesting version comes from a quantum line $\mathbb{R}^1_q$ coupled with a time variable (e.g. $A_q = C(\mathbb{R}) \otimes \mathbb{R}^1_q$) with e.g. $x\Lambda = q\Lambda x$; $xdx = qdxx$; $dx\Lambda = q\Lambda dx$; $xd\Lambda = qd\Lambda x$; $e_1 x = q\Lambda x$ and $e_1\Lambda = 0$; $df(e_1) = e_1 f$; $e_2\Lambda = q\Lambda x$; $e_2 x = 0$; $df(e_2) = e_2 f$ (Λ is introduced for technical reasons (cf. ref. [16])). The MC equations are **(A78)** $d\omega_0 = \mathfrak{Q}(\omega_0 \wedge \omega_1)$; $d\omega_1 = -\omega_0 \wedge \omega_2$; $d\omega_2 = \mathfrak{Q}(\omega_1 \wedge \omega_2)$ ($\mathfrak{Q} = q^2 + q^4$) and we must find expressions df and $d\omega$ for functions and 1-forms. After considerable calculation based on zero curvature ideas (and some assumptions on Λ, $d\Lambda$) one can say that if $u = u(x,t)$ does not depend on Λ a qKdV type equation based on the quantum line arises in the form **(A79)** $u_t = \frac{1}{\mathfrak{Q}^2}\partial^x_{q^{-1}}(\partial^x_q)^2 u + \frac{\eta}{\mathfrak{Q}}\left((\partial^x_{q^{-1}}D_x)^2 - D_x^{-1}(\partial^x_q)^2\right)u - \frac{1}{\mathfrak{Q}}[q(\partial^x_q)D_x u + (1+q)u\partial^x_q u] + \eta u(1 - D_x)u$.

7 Moyal approach

One knows that Moyal quantization plays an important role in mathematical physics (for discussion cf. ref. [5, 15]). In fact KP can be identified with a Moyal quantization of dKP (cf. ref. [15] for details). Generally speaking one writes

$$f * g = f \exp\left[\kappa(\overleftarrow{\partial}_x \overrightarrow{\partial}_p - \overleftarrow{\partial}_p \overrightarrow{\partial}_x\right] g = f\left(x + \kappa\overrightarrow{\partial}_p, p - \kappa\overrightarrow{\partial}_x\right) g(x,p) \tag{45}$$

and $\{f,g\}_M = (f*g - g*f)/2\kappa$ is the Moyal bracket. This leads to **(A80)** $\{f,g\}_M = \frac{1}{\kappa}\{f\sin[\kappa(\overleftarrow{\partial}_x\overrightarrow{\partial}_p - \overleftarrow{\partial}_p\overrightarrow{\partial}_x)]g\}$. One can also write (using x, t variables and $\kappa \sim \theta/2$) **(A81)** $f * g = m \circ \exp(\theta P/2)(f \otimes g)$; $m(f\otimes g) = fg$; $P = \partial_t \otimes \partial_x - \partial_x \otimes \partial_t$. Now go to ref. [28] as developed in ref. [15] where one deals with bicomplexes (BC) $M = \oplus_{r\geq 0} M^r$ with linear maps $d, \delta : M^r \to M^r$ satisfying **(A82)** $d^2 = \delta^2 = d\delta + \delta d = 0$ (note δ is not the standard metric adjoint). In the spirit of Examples 1, 2 one develops zero curvature equations to produce integrable equations such as KdV and KP.

Example 7. Let $M = C^\infty(\mathbb{R}^3)\otimes\Lambda_2$ ($\Lambda_2 \sim \oplus_0^2\Lambda^j$) with **(A83)** $df = (f_t - f_{xxx})\tau + (1/2)(f_y - f_{xx})\xi$ and $\delta f = (3/2)(f_y + f_{xx})\tau + f_x\xi$ where $\tau, \xi \in \Lambda^1$. Deform now (or "dress") d to $Df = df + \delta(vf) - v\delta(f)$ so

$$Df = [f_t - f_{xxx} + (3/2)(v_y + v_{xx})f + 3v_x f_x]\tau + (1/2)(f_y - f_{xx} + 2v_x f)\xi. \tag{46}$$

Then the required BC condition $D^2 = 0$ becomes **(A84)** $v_{xt} - (1/4)v_{xxxx} + 3v_x v_{xx} - (3/4)v_{yy} = 0$ which is equivalent to KP for $u \sim -v_x$. There are also other forms of dressing of one BC to another while preserving the BC conditions. The underlying ideas here are zero curvature, cohomology (to get hierarchies), and gauge transformations (involving Seiberg–Witten (SW) maps – cf. ref. [5, 15]). In particular SW maps preserve zero curvature and e.g. solutions of the KdV equation determine solutions of a noncommutative KdV (NCKdV) equation in a manner similar to what happens with the SW map between commutative and noncommutative gauge theories (cf. ref. [15, 28] for details). Thus take $M = C^\infty(\mathbb{R}^2)\otimes\Lambda_2$ with $\tau, \xi \in \Lambda^1$ satisfying $\tau^2 = \xi^2 = \tau\xi + \xi\tau = 0$. One can then define d, δ on $M^0 = C^\infty(\mathbb{R}^2)$ and extend by linearity via $d(f\tau + h\xi) = (df)\tau + (dh)\xi$ for example. Start with **(A85)** $df = -f_{xx}\xi + (f_t + 4f_{xxx})\tau$ and $\delta f = f_x\xi - 3f_{xx}\tau$ (similar to Example 1). Apply a dressing to d in the form ($u = \phi_x$)

$$Df = df + \delta(\phi * f) - \phi * \delta f = -(f_{xx} + u * f)\xi + (f_t + 4f_{xxx} - 6u * f_x - 3u_x * f)\tau \tag{47}$$

(note ∂_x and ∂_t are derivations for $*$ which is a product as in (45) based on x, t). The only nontrivial BC equation is now $D^2 = 0$ and this is equivalent to the NCKdV equation **(A86)** $u_t + u_{xxx} - 3(u * u_x + u_x * u) = 0$. There are many more developments but we stop here.

Bi-Hamiltonian Formulation of Generalized Toda Chains

Pantelis A. DAMIANOU

Department of Mathematics and Statistic, University of Cyprus, 1678, Nicosia, Cyprus
E-mail: *damianou@ucy.ac.cy*

In this paper we prove that the Bogoyavlensky–Toda lattices corresponding to simple, classical Lie groups are bi-Hamiltonian. We illustrate in detail the case of B_N Toda systems.

1 Introduction

In this paper we establish for the first time the bi-Hamiltonian nature of the Toda lattices corresponding to classical simple Lie groups. These are systems that generalize the usual finite, non-periodic Toda lattice (which corresponds to a root system of type A_n). This generalization is due to Bogoyavlensky [2]. These systems were studied extensively in [10] where the solution of the system was connected intimately with the representation theory of simple Lie groups. There are also studies by Adler, van Moerbeke [1] and Olshanetsky, Perelomov [15]. We call such systems the Bogoyavlensky–Toda lattices. We make the following more general definition which involves systems with exponential interaction: Consider a Hamiltonian of the form

$$H = \frac{1}{2}(\boldsymbol{p}, \boldsymbol{p}) + \sum_{i=1}^{m} e^{(\boldsymbol{v}_i, \boldsymbol{q})}, \tag{1}$$

where $\boldsymbol{q} = (q_1, \ldots, q_N)$, $\boldsymbol{p} = (p_1, \ldots, p_N)$, $\boldsymbol{v}_1, \ldots, \boldsymbol{v}_m$ are vectors in $\mathbb{R}^N$ and $(\ ,\ )$ is the standard inner product in $\mathbb{R}^N$. The set of vectors $\Delta = \{\boldsymbol{v}_1, \ldots, \boldsymbol{v}_m\}$ is called the spectrum of the system. In this paper we limit our attention to the case where the spectrum is a system of simple roots for a simple Lie algebra $\mathcal{G}$. In this case $m = l = \operatorname{rank} \mathcal{G}$. It is worth mentioning that the case where m, N are arbitrary is an open and unexplored area of research. The main exception is the work of Kozlov and Treshchev [11] where a classification of system (1) is performed under the assumption that the system possesses N polynomial (in the momenta) integrals. Such systems are called Birkhoff integrable.

Example. The usual Toda lattice corresponds to a Lie algebra of type A_{N-1}. In other words, $l = N - 1$ and we choose Δ to be the set:

$$\boldsymbol{v}_1 = (1, -1, 0, \ldots, 0), \quad \ldots\ldots\ldots, \quad \boldsymbol{v}_{N-1} = (0, 0, \ldots, 0, 1, -1).$$

The Hamiltonian becomes:

$$H(q_1, \ldots, q_N, p_1, \ldots, p_N) = \sum_{i=1}^{N} \frac{1}{2} p_i^2 + \sum_{i=1}^{N-1} e^{q_i - q_{i+1}}, \tag{2}$$

which is the well-known classical Toda lattice.

The results of this paper were announced in [5] where it was pointed out that the higher Toda flows of the B_N, C_N and D_N systems are bi-Hamiltonian, but there was no similar result for the initial flow. Usually, it is more convenient to work instead in the space of the natural (q, p) variables, with the Flaschka variables (a, b). We end-up with a new set of polynomial equations

in the variables (a, b). One can write the equations in Lax pair form. The Lax pair $(L(t), B(t))$ in $\mathcal{G}$ can be described in terms of the root system. The symplectic bracket is transformed in (a, b) coordinates into a Lie–Poisson bracket denoted by π_1. The construction of the bi-Hamiltonian pair may be summarized as follows: Define a recursion operator $\mathcal{R}$ in (a, b) space by finding a second bracket, π_3, and inverting the initial Poisson bracket π_1. Define the negative recursion operator $\mathcal{N}$ by inverting the second Poisson bracket π_3. This recursion operator is the inverse of the operator $\mathcal{R}$. Finally, define a new rational bracket π_{-1} by $\pi_{-1} = \mathcal{N}\pi_1 = \pi_1\pi_3^{-1}\pi_1$. We obtain a bi-Hamiltonian formulation of the system:

$$\pi_1 \nabla H_2 = \pi_{-1} \nabla H_4,$$

where $H_i = \frac{1}{i} \operatorname{tr} L^i$. The brackets π_1 and π_{-1} are compatible and Poisson. In this paper we treat in detail the B_N case. For complete results and full proofs for all classical simple Lie groups, see [6]. We begin with a review of the classical Toda lattice.

2 A_N Toda lattice

Equation (2) is the classical, finite, nonperiodic Toda lattice. This system was investigated in [7–9, 13, 14] and in numerous of other papers that are impossible to list here. To determine the constants of motion, one uses Flaschka's transformation:

$$a_i = \frac{1}{2} e^{\frac{1}{2}(q_i - q_{i+1})}, \qquad b_i = -\frac{1}{2} p_i.$$

Then Hamilton's equations become

$$\dot{a}_i = a_i(b_{i+1} - b_i),$$
$$\dot{b}_i = 2(a_i^2 - a_{i-1}^2).$$

These equations can be written as a Lax pair $\dot{L} = [B, L]$, where L is the Jacobi matrix

$$L = \begin{pmatrix} b_1 & a_1 & 0 & \cdots & \cdots & 0 \\ a_1 & b_2 & a_2 & \cdots & & \vdots \\ 0 & a_2 & b_3 & \ddots & & \\ \vdots & & \ddots & \ddots & & \vdots \\ \vdots & & & \ddots & \ddots & a_{N-1} \\ 0 & \cdots & & \cdots & a_{N-1} & b_N \end{pmatrix},$$

and B is the skew-symmetric part of L (In the decomposition, lower Borel plus skew-symmetric). This is an example of an isospectral deformation; the entries of L vary over time but the eigenvalues remain constant. It follows that the functions $H_i = \frac{1}{i} \operatorname{tr} L^i$ are constants of motion.

Consider $\mathbb{R}^{2N}$ with coordinates $(q_1, \ldots, q_N, p_1, \ldots, p_N)$, the standard symplectic bracket

$$\{f, g\}_s = \sum_{i=1}^{N} \left(\frac{\partial f}{\partial q_i} \frac{\partial g}{\partial p_i} - \frac{\partial f}{\partial p_i} \frac{\partial g}{\partial q_i} \right),$$

and the mapping $F : \mathbb{R}^{2N} \to \mathbb{R}^{2N-1}$ defined by

$$F : (q_1, \ldots, q_N, p_1, \ldots, p_N) \to (a_1, \ldots, a_{N-1}, b_1, \ldots, b_N).$$

There exists a bracket on $\mathbb{R}^{2N-1}$, which satisfies

$$\{f,g\}\circ F=\{f\circ F, g\circ F\}_s\ .$$

This bracket (up to a constant multiple) is given by

$$\{a_i,b_i\}=-a_i,\qquad \{a_i,b_{i+1}\}=a_i, \tag{3}$$

all other brackets are zero. $H_1=b_1+b_2+\cdots+b_N$ is the only Casimir. The Hamiltonian in this bracket is $H_2=\frac{1}{2}\operatorname{tr}L^2$. The Lie algebraic interpretation of this bracket can be found in [10]. We denote this bracket by π_1. The invariants H_i are in involution with respect to this Lie Poisson bracket π_1.

The quadratic Toda bracket appears in conjunction with isospectral deformations of Jacobi matrices. First, let λ be an eigenvalue of L with normalized eigenvector v. Standard perturbation theory shows that

$$\nabla\lambda=(2v_1v_2,\dots,2v_{N-1}v_N,v_1^2,\dots,v_N^2)^T:=U^\lambda\ ,$$

where $\nabla\lambda$ denotes $\left(\frac{\partial\lambda}{\partial a_1},\dots,\frac{\partial\lambda}{\partial b_N}\right)$. Some manipulations show that U^λ satisfies

$$\pi_2U^\lambda=\lambda\pi_1U^\lambda,$$

where π_1 and π_2 are skew-symmetric matrices. It turns out that π_1 is the matrix of coefficients of the Poisson tensor (3), and π_2, whose coefficients are quadratic functions of the a's and b's, that can be used to define a new Poisson tensor. It is a Poisson bracket in which the Hamiltonian vector field generated by H_1 is the same as the Hamiltonian vector field generated by H_2 with respect to the π_1 bracket. The defining relations are:

$$\{a_i,a_{i+1}\}=\frac{1}{2}a_ia_{i+1},\qquad \{a_i,b_i\}=-a_ib_i,\qquad \{a_i,b_{i+1}\}=a_ib_{i+1},\qquad \{b_i,b_{i+1}\}=2a_i^2,$$

all other brackets are zero. This bracket, due to Adler, has $\det L$ as Casimir and $H_1=\operatorname{tr}L$ is the Hamiltonian. The eigenvalues of L (and therefore the H_i as well) are still in involution. Furthermore, π_2 is compatible with π_1. We also have

$$\pi_2\nabla H_l=\pi_1\nabla H_{l+1},\qquad l=1,2,\dots. \tag{4}$$

These relations are similar to the Lenard relations for the KdV equation; they are generally called the Lenard relations. Taking $l=1$ in (4), we conclude that the Toda lattice is bi-Hamiltonian. In fact, using results from [5], we can prove that the Toda lattice is multi-Hamiltonian:

$$\pi_2\,\nabla H_1=\pi_1\nabla H_2=\pi_0\nabla H_3=\pi_{-1}\nabla H_4=\cdots\ .$$

The notion of bi-Hamiltonian system is due to Magri [12].

The sequence of Poisson tensors can be extended to form an infinite hierarchy. In order to produce the hierarchy of Poisson tensors one uses master symmetries. The first two Poisson brackets are precisely the linear and quadratic brackets we mentioned above. If a system is bi-Hamiltonian and one of the brackets is symplectic, one can find a recursion operator by inverting the symplectic tensor. The recursion operator is then applied to the initial symplectic bracket to produce an infinite sequence. However, in the case of Toda lattice (in Flaschka variables (a,b)) both operators are non-invertible and therefore this method fails. Recursion operators were introduced by Olver [16].

In the case of Toda equations, the master symmetries map invariant functions to other invariant functions. Hamiltonian vector fields are also preserved. New Poisson brackets are generated by using Lie derivatives in the direction of these vector fields and they satisfy interesting deformation relations. We quote the results from refs. [3, 4].

Theorem 1. *There exists a sequence of vector fields X_i, for $i \geq -1$, and a sequence of contravariant 2-tensors π_j, $j \geq 1$, satisfying:*

i) *π_j are all Poisson;*

ii) *the functions H_i, $i \geq 1$, are in involution with respect to all of the π_j;*

iii) *$X_i(H_j) = (i+j)H_{i+j}$, $i \geq -1$, $j \geq 1$;*

iv) *$L_{X_i}\pi_j = (j-i-2)\pi_{i+j}$, $i \geq -1$, $j \geq 1$;*

v) *$[X_i, X_j] = (j-i)X_{i+j}$, $i \geq 0$, $j \geq 0$;*

vi) *$\pi_j \nabla H_i = \pi_{j-1}\nabla H_{i+1}$, where π_j denotes the Poisson matrix of the tensor π_j.*

Remark 1. Theorem 1 was extended for all integer values of the index in [5].

Remark 2. To define the vector fields X_n one considers expressions of the form

$$\dot{L} = [B, L] + L^{n+1}.$$

This equation is similar to a Lax equation, but in this case the eigenvalues satisfy $\dot{\lambda} = \lambda^{n+1}$ instead of $\dot{\lambda} = 0$.

3 B_N Toda systems

In this section, we show that higher polynomial brackets exist also in the case of B_n Toda systems. We will prove that these systems possess a recursion operator and we will construct an infinite sequence of compatible Poisson brackets in which the constants of motion are in involution. Finally, we show that these systems are bi-Hamiltonian. The Hamiltonian for B_n is

$$H = \frac{1}{2}\sum_{1}^{n} p_j^2 + e^{q_1 - q_2} + \cdots + e^{q_{n-1}-q_n} + e^{q_n}.$$

We make a Flaschka-type transformation

$$a_i = \frac{1}{2}e^{\frac{1}{2}(q_i - q_{i+1})}, \qquad a_n = \frac{1}{2}e^{\frac{1}{2}q_n}, \qquad b_i = -\frac{1}{2}p_i.$$

Then

$$\dot{a}_i = a_i(b_{i+1} - b_i), \qquad \dot{b}_i = 2(a_i^2 - a_{i-1}^2), \qquad i = 1, \ldots, n,$$

with the convention that $a_0 = b_{n+1} = 0$.

These equations can be written as a Lax pair $\dot{L} = [B, L]$, where L is the symmetric matrix

$$L = \begin{pmatrix} b_1 & a_1 & & & & & & \\ a_1 & \ddots & \ddots & & & & & \\ & \ddots & \ddots & a_{n-1} & & & & \\ & & a_{n-1} & b_n & a_n & & & \\ & & & a_n & 0 & -a_n & & \\ & & & & -a_n & -b_n & \ddots & \\ & & & & & \ddots & \ddots & -a_1 \\ & & & & & & -a_1 & -b_1 \end{pmatrix},$$

and B is the skew-symmetric part of L (In the decomposition, lower Borel plus skew-symmetric). We note that the determinant of L is zero.

In the new variables a_i, b_i, the canonical bracket on $\mathbb{R}^{2N}$ is transformed into a bracket π_1 which is given by

$$\{a_i, b_i\} = -a_i, \qquad \{a_i, b_{i+1}\} = a_i.$$

It is easy to show by induction that

$$\det \pi_1 = a_1^2 a_2^2 \cdots a_n^2.$$

The invariant polynomials for B_n, which we denote by

$$H_2, \quad H_4, \quad \ldots, \quad H_{2n}$$

are defined by $H_{2i} = \frac{1}{2i} \operatorname{Tr} L^{2i}$.

We look for a bracket π_3 which satisfies

$$\pi_3 \nabla H_2 = \pi_1 \nabla H_4 \ .$$

We define the following homogeneous cubic bracket π_3:

$$\begin{aligned}
&\{a_i, a_{i+1}\} = a_i a_{i+1} b_{i+1}, \qquad \{a_i, b_i\} = -a_i b_i^2 - a_i^3, \qquad \{a_n, b_n\} = -a_n b_n^2 - 2a_n^3,\\
&\{a_i, b_{i+2}\} = a_i a_{i+1}^2, \qquad \{a_i, b_{i+1}\} = a_i b_{i+1}^2 + a_i^3, \qquad \{a_i, b_{i-1}\} = -a_{i-1}^2 a_i,\\
&\{b_i, b_{i+1}\} = 2a_i^2(b_i + b_{i+1}), \qquad i = 1, 2, \ldots, n-1
\end{aligned}$$

We summarize the properties of this new bracket in the following:

Theorem 2. *The bracket π_3 satisfies the following:*

1. *π_3 is Poisson;*
2. *π_3 is compatible with π_1;*
3. *H_{2i} are in involution.*

Define $\mathcal{R} = \pi_3 \pi_1^{-1}$. Then $\mathcal{R}$ is a recursion operator. We obtain a hierarchy

$$\pi_1, \ \pi_3, \ \pi_5, \ \ldots$$

consisting of compatible Poisson brackets of odd degree in which the constants of motion are in involution.

4. *$\pi_{j+2} \operatorname{grad} H_{2i} = \pi_j \operatorname{grad} H_{2i+2} \ \forall \ i, \ j$.*

The proof of this result is in [4].

Following the procedure outlined in the introduction we obtain a bi-Hamiltonian formulation of the system. In other words, we define $\pi_{-1} = \mathcal{N}\pi_1 = \pi_1 \pi_3^{-1} \pi_1$ and use it to obtain the desired formulation. We illustrate with the B_2 Toda system. In this case $\det \pi_1 = a_1^2 a_2^2$ and $\det \pi_3 = a_1^2 a_2^2 \Delta^2 = \det \pi_1 \Delta^2$, where

$$\Delta = a_1^4 + 2a_2^2 a_1^2 + 2a_2^2 b_1^2 + b_1^2 b_2^2 - 2a_1^2 b_1 b_2.$$

The explicit formula for π_{-1} is

$$\pi_{-1} = \frac{1}{\Delta} A,$$

where

$$A=\begin{pmatrix} 0 & -a_1a_2b_2 & -a_1(b_2^2+a_1^2+2a_2^2) & a_1(b_1^2+a_1^2+2a_2^2)\\ a_1a_2b_2 & 0 & a_1^2a_2 & -a_2(b_1^2+2a_1^2)\\ a_1(b_2^2+a_1^2+2a_2^2) & -a_1^2a_2 & 0 & -2a_1^2(b_1+b_2)\\ -a_1(b_1^2+a_1^2+2a_2^2) & a_2(b_1^2+2a_1^2) & 2a_1^2(b_1+b_2) & 0 \end{pmatrix}.$$

This bracket is Poisson by construction. It is also compatible with π_1. We note that $\Delta=\sqrt{\det\mathcal{R}}$ and it is also equal to the product of the non-zero eigenvalues of L. Using the rational bracket π_{-1} we establish the bi-Hamiltonian nature of the system, i.e.

$$\pi_1\nabla H_2=\pi_{-1}\nabla H_4.$$

In fact the system is multi-Hamiltonian:

$$\pi_1\nabla H_2=\pi_{-1}\nabla H_4=\pi_{-3}\nabla H_6=\cdots,$$

where

$$\pi_{-(2i-1)}=\mathcal{N}^i\pi_1.$$

On Construction of Zero-Curvature Representations for Some Chiral-Type Three-Field Systems

Dmitry K. DEMSKOI

Oryol State University, 95 Komsomolskaya Str., 302015 Oryol, Russia
E-mail: *demskoy@iname.com*

The problem of construction of matrix zero-curvature representations for some chiral-type three field systems is considered. The systems belong to the class described by the Lagrangian $L = \frac{1}{2} g_{ij}(u) u^i_x u^j_t + f(u)$, where g_{ij} is the metric of three-dimensional reducible Riemannian space. The investigation is based on the analysis of evolutionary system $u_t = S(u)$, where S is a higher symmetry.

1 Introduction

We consider here the systems belonging to the following class of two-dimensional fields

$$u^i_{tx} + \Gamma^i_{jk}(u) u^j_x u^k_t = f^i(u), \qquad f^i = g^{ij} \frac{\partial f}{\partial u^j}, \tag{1}$$

where g^{ij} is the metric tensor and Γ^i_{jk} are the Christoffel symbols of the configurational space with the coordinates u^i, the low indices x and t denote the partial derivatives, also we assume summation over repeating indices. The system (1) possesses the following Lagrangian

$$L = \frac{1}{2} g_{ij}(u) u^i_x u^j_t + f(u).$$

In the article [2] the systems with the Lagrangian

$$L = \frac{1}{2} \left(u_t u_x + \psi(v, w)(v_t w_x + v_x w_t) \right) + f(u, v, w), \tag{2}$$

were studied. There we found the systems possessing the nontrivial higher polynomial (with respect to derivatives $u^i_n = \partial u^i / \partial x^n$) symmetries of the 2nd, 3rd, 4th or 5th order. It was proved that the non-degenerate symmetries exist if and only if $\psi = (vw + c)^{-1}$, $c = \text{const}$, and f takes one of the following forms

$$f = ave^{\sqrt{2}u} + bwe^{-\sqrt{2}u}, \tag{3a}$$
$$f = av^2 e^{2u} + bw^2 e^{-2u}, \tag{3b}$$
$$f = av^2 e^{2u} + bwe^{-u}, \tag{3c}$$
$$f = ave^{u} + bwe^{-u}, \tag{3d}$$
$$f = (vw + c/2) \left[ae^{\sqrt{2}u} + be^{-\sqrt{2}u} \right], \tag{3e}$$
$$f = a\,(vw + c/2)\, e^{\sqrt{2}u} + be^{-\sqrt{2}u}, \tag{3f}$$
$$f = a\,(vw + c/2)\, e^{\sqrt{2}u} + be^{-2\sqrt{2}u}, \tag{3g}$$
$$f = \left(v^2 w + 2/3\, vc \right) e^{\sqrt{2}u}, \tag{3h}$$
$$f = ve^{\sqrt{2/3}u}, \tag{3i}$$

where a and b are arbitrary constants. We assume that $c \neq 0$, so the connection Γ^i_{jk} is nontrivial.

Evidently the simplest case for investigation is when function f is linear with respect to v and w. Among the two-exponential functions (3a)–(3g) there are only two functions of that kind, they are given by (3a), (3d). Hyperbolic systems (1) corresponding to these functions have the following forms

$$u_{tx} = \sqrt{2}\big[ave^{\sqrt{2}u} - bwe^{-\sqrt{2}u}\big], \qquad v_{tx} = b\psi^{-1}e^{-\sqrt{2}u} + \psi w v_x v_t,$$
$$w_{tx} = a\psi^{-1}e^{\sqrt{2}u} + \psi v w_x w_t, \tag{4}$$

and

$$u_{tx} = ave^{u} - bwe^{-u}, \qquad v_{tx} = b\psi^{-1}e^{-u} + \psi w v_t v_x, \qquad w_{tx} = a\psi^{-1}e^{u} + \psi v w_t w_x. \tag{5}$$

It was shown in [3] that each system posessing Lagrangian (2) can be represented in an explicit Hamiltonian form

$$u_t = D_x^{-1}\frac{\delta H}{\delta u}, \qquad v_t = e^{\varphi}D_x^{-1}e^{-\varphi}\psi^{-1}\frac{\delta H}{\delta w}, \qquad w_t = \psi^{-1}e^{-\varphi}D_x^{-1}e^{\varphi}\frac{\delta H}{\delta v},$$

which is possibly nonlocal. Existence of the Hamiltonian form gives us a hope that both systems (4) and (5) are the first nonlocal members of the corresponding sequences of integrable Hamiltonian evolution systems

$$\boldsymbol{u}_{t_n} = S_n(\boldsymbol{u}) = J^{-1}\frac{\delta H_n}{\delta \boldsymbol{u}}, \tag{6}$$

where J^{-1} is Hamiltonian operator, S_0 is a corresponding nonlocal vector field, $S_1(\boldsymbol{u}) = \boldsymbol{u}_x$ and S_n, $n > 1$ are higher order vector fields; H_n are the corresponding Hamiltonians.

2 Zero-curvature representations

If a nonlinear system can be represented as the compatibility condition of a linear system $\Psi_x = U\Psi$, $\Psi_t = V\Psi$, i.e. as

$$U_t - V_x + [U, V] = 0, \tag{7}$$

then the system is said to possess zero-curvature representation. In the equation (7) $[U, V]$ is the commutator of matrices. The matrices U, V depend on field functions, and finite set of theirs derivatives, and on a parameter λ, usually called the spectral parameter.

The zero-curvature representation can be constructed starting directly from equation (7). For simplicity, one can choose the matrices U, V in the form

$$U = U_i(u)u_x^i + \overline{U}(u), \qquad V = V_i(u)u_t^i + \overline{V}(u) \tag{8}$$

(this choice corresponds to the solutions given below). Substituting (8) to (7), and requiring the system (1) to be obtained, one can obtain a matrix system for U_i, V_i, $\overline{U}$, and $\overline{V}$ involving covariant derivatives:

$$\nabla_j U_i - \nabla_i V_j + [U_i, V_j] = 0, \qquad f^i(U_i - V_i) + [\overline{U}, \overline{V}] = 0,$$
$$\nabla_i \overline{U} + [\overline{U}, V_i] = 0, \qquad \nabla_i \overline{V} + [\overline{V}, U_i] = 0. \tag{9}$$

The direct computation of the matrices U and V from the equations (9) is a fundamentally difficult problem, and we therefore use a different approach. Existence of the explicit Hamiltonian

form allows expecting that the systems (4) and (5) are nonlocal terms of hierarchies of evolutionary systems $u_t = S_n(u)$. Adopting this assumption we can try to find the zero curvature representation for any system (6) in the following form

$$U_{,t} - V_{n,x} + [U, V_n] = 0. \tag{10}$$

The matrix U must be one and the same for all equations of the hierarchy, but the matrices V_n are different. For the evolution systems such problems are usually solvable by the prolongation method [4, 5]. We assume that the matrix U for systems (4) and (5) has form (8). Replacing in (7) u_t, v_t, and w_t according to (6), we obtain matrices U, V in the form

$$U = \sum_i p_i(u) u_x^i A_i + \sum_j q_j(u) A_j, \qquad V_n = \sum_i g_i(u, u_1, \dots, u_k) A_i, \tag{11}$$

where k is the order of a higher symmetry $S_n(u)$, A_i are some constant matrices which satisfy commutation relations

$$[A_i, A_j] = C_{ij}^k A_k. \tag{12}$$

Note, that table of commutators (12) is not closed. There are some ways to solve the systems like (12). For example, one can choose one of the matrices in the Jordan normal form and try to solve the equations directly. But this way leads to an excessive branching if the matrix size is large. Therefore we applied a modification of the prolongation method by H.D. Wahlquist and F.B. Estabrook [4, 5] to close the table of commutators (12). There are two possibilities for any unknown commutator $[A_i, A_j]$:

(i) $[A_i, A_j]$ is a linear combination of the known elements of the Lie algebra or (ii) $[A_i, A_j]$ is a new element linearly independent of the previous elements. In the first case we write $[A_i, A_j]$ as a linear combination of all elements $A_1, \dots, A_n$ which we have for the current step and try to find the coefficients with the help of the Jacobi identity. In the second case we introduce the new element $A_{n+1} = [A_i, A_j]$ of the algebra. Then using the Jacobi identity we try to find the new commutational relations for A_{n+1} and so on. After a number of such steps we obtain a closed table of commutators. The obtained algebra can possess a centre. To obtain an algebra with the lowest dimension we construct a factor algebra, setting the elements of the centre as zeros. As a result, the matrices U and V were always embedded into simple classical algebras. To construct a representation of resulting algebra we use the standard algorithm: find a Cartan subalgebra, construct a Cartan–Weyl basis, and build all the matrices explicitly.

Zero-curvature representation for system (4). The simplest higher symmetry of this system is

$$\begin{aligned} &u_{t_1} = \sqrt{2}\psi v_x w_x, \qquad v_{t_1} = v_{xx} - 2v\psi v_x w_x + \sqrt{2} u_x v_x, \\ &w_{t_1} = -w_{xx} + 2w\psi v_x w_x + \sqrt{2} u_x w_x. \end{aligned} \tag{13}$$

Using prolongation technique of Whalquist–Estabrook we obtain the following matrices of the zero-curvature representation for system (13)

$$U = \begin{pmatrix} 0 & -v^{-1}(3vw + c)be^{-\sqrt{2}u} & \frac{2c^2}{3} v^{-1} v_x \psi \\ 0 & \frac{c}{3} v^{-1} v_x \psi & \lambda v a e^{\sqrt{2}u} \\ \frac{1}{3} v^{-1} v_x \psi & v^{-1} b e^{-\sqrt{2}u} & -\frac{c}{3} v^{-1} v_x \psi \end{pmatrix}, \tag{14}$$

$$V_1 = \begin{pmatrix} -\lambda ab & 3be^{-\sqrt{2}u} w_x & 2c^2 g - \lambda ab(3vw + c) \\ \frac{\lambda}{3} a e^{\sqrt{2}u} v_x \psi & cg & \left(1 - \frac{2}{3} c\psi\right) \lambda a e^{\sqrt{2}u} v_x \\ g & 0 & -cg \end{pmatrix}, \tag{15}$$

here

$$g = v^{-1}\psi(v_{xx} + \sqrt{2}v_x u_x)/3 - \psi^2 v_x w_x/3.$$

Now we can obtain the matrix V_0 for original hyperbolic system (4). Substituting matrix (14) to equation (10), one can easily find that the matrix V_0 has the following form

$$V_0 = u_t B_1 + v^{-1}v_t B_2 + w_t v\psi B_3 + B_4.$$

The constant matrices B_i are of the form

$$B_1 = \sqrt{2}/3(\boldsymbol{e}_{22} - \boldsymbol{e}_{11} - \boldsymbol{e}_{33}), \qquad B_4 = \lambda^{-1}(2c\boldsymbol{e}_{12} + \boldsymbol{e}_{32}) - (\boldsymbol{e}_{21} + c\boldsymbol{e}_{23})/3,$$
$$B_2 = (\boldsymbol{e}_{11} + \boldsymbol{e}_{22} - 2\boldsymbol{e}_{33})/3 + c\boldsymbol{e}_{13}, \qquad B_3 = (2\boldsymbol{e}_{11} - \boldsymbol{e}_{22} - \boldsymbol{e}_{33})/3 - 2c\boldsymbol{e}_{13},$$

here $\boldsymbol{e}_{ij}$ are the Weyl matrices. Thus the matrix V is given by

$$V_0 = \begin{pmatrix} h_1 & 2c\lambda^{-1} & cv^{-1}v_t - 2cw_t v\psi \\ -1/3 & h_2 - h_1 & -c/3 \\ 0 & \lambda^{-1} & -h_2 \end{pmatrix}, \tag{16}$$

where $h_1 = \frac{1}{3}(v^{-1}v_t + 2w_t v\psi - \sqrt{2}u_t)$, $h_2 = \frac{1}{3}(2v^{-1}v_t + w_t v\psi + \sqrt{2}u_t)$.

Zero-curvature representation for system (5). The simplest higher symmetry of this system is

$$\begin{aligned}
u_t &= -\frac{1}{2}u_{xxx} + \frac{3}{2}\psi(v_{xx}w_x - v_x w_{xx}) + \frac{1}{4}u_x^3 + \frac{9}{2}\psi u_x v_x w_x + \frac{3}{2}\psi^2 v_x w_x(v_x w - v w_x), \\
v_t &= v_{xxx} + \frac{3}{2}u_{xx}v_x + 3v_{xx}(u_x - \psi v w_x) + \frac{9}{4}u_x^2 v_x - 6\psi u_x v v_x w_x + 3\psi v_x w_x\left(\psi v^2 w_x - \frac{1}{2}v_x\right), \\
w_t &= w_{xxx} - \frac{3}{2}u_{xx}w_x - 3w_{xx}(u_x + \psi v_x w) + \frac{9}{4}u_x^2 w_x + 6\psi u_x v_x w w_x \\
&\quad + 3\psi v_x w_x\left(\psi w^2 v_x - \frac{1}{2}w_x\right).
\end{aligned} \tag{17}$$

The matrices U and V_1 of the zero-curvature representation for the system (17) is embedded into $sl(4,\mathbb{C})$. The matrix U is given by

$$U = \begin{pmatrix} -\frac{1}{2}w\psi v_1 & -\lambda e^u & 0 & -we^{-u} \\ -\psi^{-1}e^{-u} & \frac{1}{2}w\psi v_1 & we^{-u} & 0 \\ 0 & -\lambda v e^u & \frac{1}{2}w\psi v_1 & -\psi^{-1}e^{-u} \\ -\lambda v e^u & 0 & \lambda e^u & -\frac{1}{2}w\psi v_1 \end{pmatrix}. \tag{18}$$

The matrix V_1 is too cumbersome, and we omit it. Let us consider now the zero-curvature representation for the hyperbolic system (5). We take the matrix U in the form (18), and moreover, we assume that the matrix V_0 is linear with respect to u_t, v_t and w_t

$$V_0 = f_1 u_t + f_2 v_t + f_3 w_t + f_4.$$

If one substitutes V_0 into the equation (10) and substitutes therein u_{tx}, v_{tx} and w_{tx} from (5), then this equation must be an identity. This implies, in particular

$$f_1 = C_1, \qquad f_2 = C_2, \qquad f_4 = C_4, \qquad f_3 = f_3(v,w),$$

where C_i are constant matrices. The matrix f_3 satisfies the system

$$\frac{\partial f_3}{\partial v} = cA_1\psi^2 + w\psi[A_1, f_3], \qquad \frac{\partial f_3}{\partial w} = -v\psi f_3,$$

which has the following general solution $f_3 = \psi(C_3 + vA_1)$, and we obtain

$$V_0 = C_1u_t + C_2v_t + \psi(C_3 + vA_1)w_t + C_4.$$

Now the equation (10) yields a considerable number of commutational relations for the constant matrices C_i and A_j. We solved these relations using (18) and found

$$C_1 = \boldsymbol{e}_{44} - \boldsymbol{e}_{22}, \qquad C_2 = \boldsymbol{e}_{31}, \qquad C_3 = \boldsymbol{e}_{13}, \qquad C_4 = \frac{b}{2}(\boldsymbol{e}_{32} - \boldsymbol{e}_{41}) - \frac{a}{2\lambda}(\boldsymbol{e}_{14} + \boldsymbol{e}_{23}),$$

and

$$V_0 = \begin{pmatrix} -\frac{1}{2}\psi w_t v & 0 & \psi w_t & -a/(2\lambda) \\ 0 & -u_t + \frac{1}{2}\psi w_t v & -a/(2\lambda) & 0 \\ v_t & b/2 & \frac{1}{2}\psi w_t v & 0 \\ -b/2 & 0 & 0 & u_t - \frac{1}{2}\psi w_t v \end{pmatrix}. \tag{19}$$

3 Conserved currents

To construct the conserved currents of the systems (4) and (5) we use the algorithm presented in [1]. Let the vector function Ψ satisfy the system

$$\Psi_x = U\Psi, \qquad \Psi_t = V\Psi. \tag{20}$$

Introducing the function $\Phi = \Psi/(C, \Psi)$ where (C, Ψ) is the Euclidean scalar product and C is a constant vector, one can easily check that

$$\Phi_x = U\Phi - \Phi(C, U\Phi), \qquad \Phi_t = V\Phi - \Phi(C, V\Phi), \qquad (C, \Phi) = 1. \tag{21}$$

Multiplying (20) by vector $C/(C, \Psi)$ we obtain $(\log(C, \Psi))_x = (C, U\Phi)$, $(\log(C, \Psi))_t = (C, V\Phi)$. This implies the following conservation law

$$D_t(C, U\Phi) = D_x(C, V\Phi). \tag{22}$$

Expanding now Φ in a power series with respect to λ, one can obtain an infinite sequence of local conserved currents. Hence we may call the functions

$$R = (C, U\Phi) \qquad \text{and} \qquad T = (C, V_0\Phi) \tag{23}$$

the generating functions for the conserved densities and the fluxes accordingly.

Conserved currents for system (4). Let us consider equations (21) with matrices (14) and (16), where we set $a = 1$ and assume that $b \neq 0$. In this case, we can choose $c = (0, 1, 0)$. Then identity $(c, \varphi) = 1$ implies that $\varphi = (\varphi_1, 1, \varphi_3)$, and the first system in (21) takes the following form

$$\Phi_x = -c\frac{v_x}{v}\psi\Phi - 3b\frac{e^{-\sqrt{2}u}}{v\psi} - \lambda v e^{\sqrt{2}u}\Phi\varphi_3, \qquad \varphi_{3,x} = \frac{v_x}{3v}\psi\Phi + b\frac{e^{-\sqrt{2}u}}{v} - \lambda v e^{\sqrt{2}u}\varphi_3^2, \tag{24}$$

where $\Phi = \varphi_1 - 2c\varphi_3$. Generating functions (23) are then written as

$$\rho = \lambda v e^{\sqrt{2}u}\varphi_3 + \frac{cv_x}{3v}\psi, \qquad \theta = \frac{1}{3}\left(2\sqrt{2}u_t + \frac{v_t}{v} - vw_t\psi\right) - c\varphi_3 - \frac{1}{3}\Phi. \tag{25}$$

To obtain WKB-expansion for system (24), we set

$$\lambda = k^2/b, \qquad \Phi = gk^{-1}v^{-1}b\exp(-\sqrt{2}u), \qquad \varphi_3 = hk^{-1}v^{-1}b\exp(-\sqrt{2}u),$$

then equations (24) take simpler form

$$h_x = \left(\frac{v_x}{v} + \sqrt{2}u_x\right)h + \frac{v_x}{3v}\psi g + k(1-h^2), \quad g_x = (v_x w\psi + \sqrt{2}u_x)g - k(3\psi^{-1} + gh). \tag{26}$$

It is now clear that the expansions for g, and h must be given by

$$h = 1 + \sum_{i=1}^{\infty} h_i k^{-i}, \qquad g = -3\psi^{-1} + \sum_{i=1}^{\infty} g_i k^{-i}. \tag{27}$$

Substituting this expansions in (26), we get the recursion relations

$$\begin{aligned}
&h_{i+1} = \frac{1}{2}\left(\sqrt{2}u_x + \frac{v_x}{v}\right)h_i - \frac{1}{2}D_x h_i + \frac{v_x}{6v}\psi g_i - \frac{1}{2}\sum_{j=1}^{i} h_j h_{i-j+1},\\
&g_{i+1} = 3\psi^{-1}h_{i+1} + (\sqrt{2}u_x + v_x w\psi)g_i - D_x g_i - \sum_{j=1}^{i} h_j g_{i-j+1},\\
&h_1 = u_x/\sqrt{2}, \qquad g_1 = 3vw_x - 3/\sqrt{2}\,u_x\psi^{-1},
\end{aligned} \tag{28}$$

where $i \geqslant 1$. Applying all the substitutions to (25), we obtain the series

$$\rho = k + \sum_{i=0}^{\infty} \rho_i k^{-i}, \qquad \theta = \sum_{i=0}^{\infty} \theta_i k^{-i},$$

which determine canonical conserved currents (ρ_i, θ_i) of the system (4):

$$\begin{aligned}
&\rho_0 = \frac{\sqrt{2}}{2}u_x + \frac{cv_x}{3v}\psi, \qquad \rho_i = h_{i+1}, \qquad i \geq 1,\\
&\theta_0 = \frac{1}{3}\left(2\sqrt{2}u_t + \frac{v_t}{v} - vw_t\psi\right), \qquad \theta_1 = wb\exp(-\sqrt{2}u),\\
&\theta_{i+1} = -v^{-1}b\exp(-\sqrt{2}u)\,(ch_i + g_i/3), \qquad i \geq 1.
\end{aligned} \tag{29}$$

With the help of relations (28), and (29) one can easily obtain any number of conserved currents. For example

$$\begin{aligned}
&\rho_1 = -\frac{\sqrt{2}}{4}\omega_1, \qquad \rho_2 = \frac{\sqrt{2}}{8}D_x(\omega_1) - \frac{1}{2}\omega_3,\\
&\rho_3 = \frac{3}{4}D_x(\omega_3) - \frac{\sqrt{2}}{16}D_x^2(\omega_1) - \frac{1}{16}\omega_1^2 - \frac{1}{2}\omega_2\omega_3, \qquad \theta_2 = -b\exp(-\sqrt{2}u)\left(w_x - \frac{\sqrt{2}}{2}wu_x\right),\\
&\theta_3 = bw\exp(-\sqrt{2}u)\left(-\frac{\sqrt{2}}{4}\omega_1 + (v_x w\psi)^{-1}\omega_3\right),
\end{aligned}$$

where the functions ω_i are given by

$$\begin{aligned}
&\omega_1 = (\sqrt{2}u_2 - u_1^2 - 2v_1 w_1\psi)/6, \qquad \omega_2 = v_2 v_1^{-1} + u_1/\sqrt{2} - \psi w_1 v,\\
&\omega_3 = \psi v_1(w_2 - v_1 w_1\psi w - \sqrt{2}u_1 w_1).
\end{aligned} \tag{30}$$

Conserved currents for system (5). To construct the conserved currents for the system (5), let us simplify the matrix U with the help of the gauge transformation $\widetilde{U} = S^{-1}(US - S_x)$, $\widetilde{V}_0 = S^{-1}(V_0 S - S_t)$. We choose the matrix S in the following form

$$S = \exp(-\varphi/2) \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & e^{-u} & 0 & 0 \\ v & 0 & 1 & 0 \\ 0 & 0 & 0 & e^{u} \end{pmatrix},$$

where $\varphi = D_x^{-1}\psi w v_1$ is the quasi-local variable: $D_t\varphi = \psi v w_t - u_t$. Then the transformed matrices are

$$\widetilde{U} = \begin{pmatrix} 0 & -\lambda & 0 & -w \\ -c & \psi w v_1 + u_1 & w & 0 \\ -c\psi v_1 & 0 & \psi w v_1 & -c \\ 0 & 0 & \lambda & -u_1 \end{pmatrix}, \tag{31}$$

$$\widetilde{V}_0 = \begin{pmatrix} \psi v w_t - \frac{1}{2}u_t & 0 & \psi w_t & -\frac{a}{2\lambda}e^{u} \\ -\frac{av}{2\lambda}e^{u} & \psi v w_t - \frac{1}{2}u_t & -\frac{a}{2\lambda}e^{u} & 0 \\ 0 & \frac{b}{2}e^{-u} & -\frac{1}{2}u_t & \frac{av}{2\lambda}e^{u} \\ -\frac{b}{2}e^{-u} & 0 & 0 & -\frac{1}{2}u_t \end{pmatrix}. \tag{32}$$

Let us set $C = (0, 0, 0, 1)$, then the first of the systems (21) takes the following form

$$\begin{aligned} &\Phi_{1,x} = u_1\Phi_1 - \lambda\Phi_2 - w - \lambda\Phi_1\Phi_3, \qquad \Phi_{2,x} = -c\Phi_1 + (2u_1 + \psi w v_1)\Phi_2 + w\Phi_3 - \lambda\Phi_2\Phi_3, \\ &\Phi_{3,x} = -c\psi v_1\Phi_1 + (u_1 + \psi w v_1)\Phi_3 - c - \lambda\Phi_3^2. \end{aligned} \tag{33}$$

The generating functions (23) take now the simplest form

$$R = \lambda\Phi_3 - u_x, \qquad T = -(be^{-u}\Phi_1 + u_t)/2. \tag{34}$$

To obtain the local conserved densities we set $\lambda = -k^2/c$ and adopted the following formal series for Φ_i:

$$\Phi_1 = \frac{1}{k}\left(w + \sum_{i=1}^{\infty} h_i k^{-i}\right), \quad \Phi_2 = \frac{1}{k^3}\left(\frac{cw_1}{2} + \sum_{i=1}^{\infty} g_i k^{-i}\right), \quad \Phi_3 = \frac{c}{k}\left(1 + \sum_{i=1}^{\infty} \rho_i k^{-i}\right). \tag{35}$$

Substituting these series into the equations (33) we found that $\rho_1 = -u_x/2$ and the first conservation law is trivial $D_t u_x = D_x u_t$. The next conservation laws are given by

$$D_t\rho_i = D_x\frac{b}{2}e^{-u}h_{i-2}, \qquad i \geq 2, \tag{36}$$

where ρ_i and h_i satisfy the following relations

$$\rho_{i+1} = \frac{1}{2}\psi v_1 h_i - \frac{1}{2}(u_1 + \psi w v_1)\rho_i + \frac{1}{2}D_x\rho_i - \frac{1}{2}\sum_{j=0}^{i-1}\rho_{j+1}\rho_{i-j}, \qquad i \geq 1,$$

$$h_{i+1} = D_x h_i - w\rho_{i+1} - u_1 h_i - \frac{1}{c}g_i - \sum_{j=0}^{i-1}\rho_{j+1}h_{i-j}, \qquad i \geq 1,$$

$$g_{i+1} = \frac{c}{4}\delta_{i0}(w_2 - 2u_1 w_1 - \psi v_1 w w_1) + \frac{1}{2}D_x g_i - cw\rho_{i+2} - \left(u_1 + \frac{1}{2}\psi w v_1\right)g_i - \frac{c}{4}w_1\rho_{i+1}$$

$$-\frac{1}{2}\sum_{j=0}^{i-1}\rho_{j+1}g_{i-j}+\frac{c}{2}D_x h_{i+1}-\frac{c}{2}u_1h_{i+1}-\frac{c}{2}\sum_{j=0}^{i}\rho_{j+1}h_{i+1-j},\qquad i\geq 0,$$

$$\rho_1=-u_1/2,\qquad g_0=0,\qquad h_0\equiv w,\qquad h_1=(w_1-u_1w)/2. \tag{37}$$

Using relations (37) we found in particular

$$\begin{aligned}
&\rho_2=\omega_1/4,\qquad \rho_3=D_x(\rho_2)/2,\qquad \rho_4=(4\omega_2-\omega_1^2+2D_x^2(\omega_1))/32,\\
&\omega_1=u_1^2/2+\psi v_1w_1-u_2,\\
&\omega_2=-\psi v_1w_3+\psi u_2v_1w_1+\psi^2v_1v_2ww_1+3\psi u_1v_1w_2+2\psi^2v_1^2ww_2\\
&\qquad-3\psi^2u_1v_1^2ww_1-2\psi u_1^2v_1w_1+c\psi^3v_1^2w_1^2+\psi^2v_1^2w_1^2/2-2\psi^3v_1^3w^2w_1.
\end{aligned} \tag{38}$$

It can be seen that $\omega_2/8-\omega_1^2/32$ is not a total derivative, hence the densities ρ_1 and ρ_3 are trivial, and ρ_2, ρ_4 are non-trivial.

It is easy to see from (29), and (36) that if we set $b=0$, then all conserved densities of the systems (4), and (5) become pseudo-constants and the systems become Liouvillian ones. To prove this statement we must present three independent pseudo-constants along each characteristic (see for instance [6]).

Obviously, functions (30) constitute complete set of pseudo-constants for system (4) along the characteristic $D_t\omega=0$. Lorentz invariance $x\longleftrightarrow t$ of the system allows us to obtain the pseudo-constants along the characteristic $D_x\omega=0$ simply by the substitutions $u_x\to u_t$, $u_{xx}\to u_{tt}$, ... from ω_1, ω_2 and ω_3.

The two obvious independent pseudo-constants of the system (5) are ω_1 and ω_2 given by (38). To find the third pseudo-constant let us rewrite the second equation of (5) under the condition $b=0$ in the following form

$$D_t\log v_x=\psi v_tw.$$

This implies $D_x(D_t\log v_x+u_t)=D_x(\psi v_tw+u_t)$. Using the conservation law $D_t\psi vw_x=D_x(\psi v_tw+u_t)$ we find $D_t(D_x\log v_x+u_x-\psi vw_x)=0$. Thus, the function

$$\omega_3=D_x\log v_x+u_x-\psi vw_x \tag{39}$$

is the third independent pseudo-constant along the characteristic $D_t\omega=0$ for system (5).

In the case when $a=0$ (and $b\neq 0$), the complete set of the pseudo-constants can be obtained with the help of the discrete symmetry of the system (5) $v\longleftrightarrow w$, $u\longrightarrow -u$.

4 Conclusion

We believe that the modification of the Wahlquist and Estabrook method applied here may be used for construction of the zero curvature representations for other hyperbolic systems too.

New Lumps of Veselov–Novikov Integrable Nonlinear Equation and New Exact Rational Potentials of Two-Dimensional Stationary Schrödinger Equation via $\overline{\partial}$-Dressing Method

V.G. DUBROVSKY and I.B. FORMUSATIK

Novosibirsk State Technical University, 20 K. Marx Ave., 630092 Novosibirsk, Russia
E-mail: *dubrovsky@online.nsk.su*

Recently calculated via $\overline{\partial}$-dressing method new lumps of 2+1-dimensional integrable nonlinear Veselov–Novikov (VN) evolution equation and exact rational potentials of two-dimensional stationary Schrödinger (2DSchr) equation with multiple pole of order two wave functions are reviewed. Among the constructed rational solutions and rational potentials are both nonsingular and singular.

1 Introduction

Exact solutions of differential equations of physics are very important for the understanding of various physical phenomena. The generation and application of new methods of calculation of exact solutions was and is actual task in all times for human scientific civilization. In the last two decades the Inverse Spectral Transform (IST) method has been generalized and successfully applied to various two-dimensional nonlinear evolution equations such as Kadomtsev–Petvashvili, Davey–Stewartson, Nizhnik–Veselov–Novikov, Zakharov–Manakov system, Ishimori, two-dimensional integrable sine-Gordon and others (see books [1–4] and references therein). The nonlocal Riemann–Hilbert problem [5], $\overline{\partial}$-problem [6] and more general $\overline{\partial}$-dressing method of Zakharov and Manakov [7–10] are now basic tools for solving two-dimensional integrable nonlinear evolution equations. Great task for mathematicians and physicists now is the generalization of IST method to multidimensional differential equations of mathematical physics.

In the present short note the results of recent calculations [19] of new exact rational so called multiple pole solutions of the famous two-dimensional integrable Veselov–Novikov (VN) nonlinear equation [11]

$$u_t + \kappa u_{zzz} + \overline{\kappa} u_{\overline{z}\overline{z}\overline{z}} + 3\kappa \left(u\partial_z^{-1} u_{\overline{z}}\right)_{\overline{z}} + 3\overline{\kappa} \left(u\partial_{\overline{z}}^{-1} u_z\right)_z = 0 \tag{1}$$

via $\overline{\partial}$-dressing method of Zakharov and Manakov are summarized. Here and in what follows $z = x + iy$, $\partial_z \equiv \frac{\partial}{\partial z} = \frac{1}{\partial 2}(\partial_x - i\partial_y)$, $\partial_{\overline{z}} \equiv \frac{\partial}{\partial \overline{z}} = \frac{1}{2}(\partial_x + i\partial_y)$; $u_z \equiv \frac{\partial u}{\partial z}$, $\partial_z^{-1}\partial_z = \partial_{\overline{z}}^{-1}\partial_{\overline{z}} = 1$; κ is arbitrary complex constant; $u(z, \overline{z}, t)$ is scalar function of space-time variables. It is well known that VN equation can be represented as compatibility condition for two linear auxiliary problems

$$\begin{aligned} &L_1\psi = \left(\partial_{z\overline{z}}^2 + u(z, \overline{z}, t)\right)\psi = 0, \\ &L_2\psi = \left(\partial_t + \kappa\partial_z^3 + \overline{\kappa}\partial_{\overline{z}}^3 + 3\kappa\left(\partial_z^{-1} u_{\overline{z}}\right)\partial_z + 3\overline{\kappa}\left(\partial_{\overline{z}}^{-1} u_z\right)\partial_{\overline{z}}\right)\psi = 0 \end{aligned} \tag{2}$$

in the form of Manakov's triad representation

$$[L_1, L_2] = BL_1, \qquad B = 3\left(\kappa\partial_z^{-1} u_{\overline{z}\overline{z}} + \overline{\kappa}\partial_{\overline{z}}^{-1} u_{zz}\right). \tag{3}$$

The $\overline{\partial}$-dressing method of Zakharov and Manakov [7–10] allows

- To construct integrable nonlinear equations together with corresponding linear auxiliary problems.
- Using the solution of linear auxiliary problems via reconstruction formula to calculate broad classes of exact solutions and to solve Cauchy problem for integrable nonlinear evolution equations.
- To construct explicitly broad classes of exactly solvable variable coefficients-fields and corresponding wave functions of linear auxiliary problems.

In conclusion of this introduction let us mention that exact integration of VN equation has remarkable history, more detailed information about all known cases of exact integration of (1) one can found in [11–15] and in doctorate dissertation of Grinevich [16], see also the review [17] and books [1–4]. The calculated in the paper [19] and reviewed in the present note multiple pole of order two rational solutions of VN equation (1) are completely new.

2 General formulas for calculating of exact multiple pole rational solutions

The basic equation of $\overline{\partial}$-dressing method in our case is the following scalar non-local $\overline{\partial}$-problem [7–9]:

$$\frac{\partial\chi}{\partial\overline{\lambda}} = (\chi * R)(\lambda,\overline{\lambda}) = \iint d\mu\wedge d\overline{\mu}\;\chi(\mu,\overline{\mu})\,R(\mu,\overline{\mu};\lambda,\overline{\lambda}) \tag{4}$$

stated here in the auxiliary space of spectral variables μ, λ. Via "long" derivatives $D_1=\partial_\xi+i\lambda$, $D_2=\partial_\eta-i\frac{i\epsilon}{\lambda}$, $D_3=\partial_t+i\left(\kappa_1\lambda^3-\kappa_2\frac{\epsilon^3}{\lambda^3}\right)$ containing the "spectral" variable λ one can construct the auxiliary linear problems for VN equation (1):

$$\begin{aligned} &L_1\chi=(D_1D_2+V_1D_1+V_2D_2+u)\chi=0,\\ &L_2\chi=\left(D_3+\kappa D_1^3+\overline{\kappa}D_2^3+W_1D_1^2+W_2D_2^2+W_3D_1+W_4D_2+W\right)\chi=0 \end{aligned} \tag{5}$$

explicitly containing the "spectral" parameter λ. In terms of the wave function

$$\psi=\chi e^{F(\lambda)},\qquad F(\lambda):=i\left(\lambda z-\frac{\epsilon}{\lambda}\overline{z}\right)-i\left(k\lambda^3-\overline{k}\frac{\epsilon^3}{\lambda^3}\right)t \tag{6}$$

the linear auxiliary problems (5) in potential case for the operator L_1 (when $V_1=V_2=0$) coincide with the problems (2). In the $\overline{\partial}$-dressing method the non-analytic wave functions χ are explored. The detailed derivation of reconstruction formulas for the variable coefficients V_1, V_2, u and W_1, W_2, W_3, W_4, W of auxiliary linear problems (5) and of the conditions of reality and potentiality in the framework of $\overline{\partial}$-dressing method in the paper [19] are presented (see also [20]).

The multiple pole solutions u of VN equation (1) correspond to special analytic structure of wave function χ (or ψ): the solution u is multiple pole solution of order m if the maximum order of pole terms in Loran expansion of χ near some points λ_k is equal to m. The solution of $\overline{\partial}$-problem (4) in the case of canonical normalization, $\chi\to\infty$ as $\lambda\to1$, is equivalent to the solution of singular integral equation:

$$\chi(\lambda)=1+\iint_C\frac{d\lambda'\wedge d\overline{\lambda'}}{2\pi i(\lambda'-\lambda)})\iint_C d\mu\wedge d\overline{\mu}\;\chi(\mu,\overline{\mu})\,R_0(\mu,\overline{\mu};\lambda',\overline{\lambda'})e^{F(\mu)-F(\lambda')}, \tag{7}$$

where $F(\lambda)$ is given by the formula (6). The kernel R_0 of $\overline{\partial}$-problem (4) in the following form corresponds to the multiple pole rational solutions u of VN equation (1):

$$R_0(\mu,\bar{\mu};\lambda,\bar{\lambda}) = \frac{\pi}{2}\sum_{p}\sum_{k,m}^{N_p} r_k^{(p)}(\mu) l_m^{(p)}(\lambda)\delta^{(k)}(\mu-\lambda_p)\delta^{(m)}(\lambda-\lambda_p). \tag{8}$$

The insertion of (8) into (7) gives the Loran expansion of wave function χ near the points $\lambda=\lambda_p$ and this leads to multiple pole solutions u of VN equation. The scheme for calculating of 2+1-dimensional integrable nonlinear evolution equations via $\overline{\partial}$-dressing method of multiple pole solutions was developed at first in the paper [18].

Let us review here some recent results [19] of calculation of exact order two multiple pole rational solutions of VN equation (1) with constant asymptotic values $-\epsilon$ at infinity:

$$u = \widetilde{u}(x,y,t) - \epsilon, \qquad \widetilde{u}(x,y,t) \underset{|z|\to\infty}{\longrightarrow} 0. \tag{9}$$

In this case the first linear auxiliary problem (5) (expressed in terms of wave function ψ (6)) in potential case ($V_1 = V_2 = 0$) coincides with problem (2a) or with two-dimensional stationary Schrödinger equation

$$(\partial^2_{z\bar{z}} + \widetilde{u})\psi = \epsilon\psi. \tag{10}$$

So the construction of exact rational multiple pole solutions u with constant asymptotic values at infinity $u \underset{|z|\to\infty}{\longrightarrow} -\epsilon$ of VN equation (1) means simultaneously construction of exact multiple pole rational potentials $\widetilde{u} := u + \epsilon$ of two-dimensional stationary Schrödinger equation (10). Recently the calculations of exact rational multiple pole of order two solutions of VN equations for the kernel R_0 of the form

$$R_0 = \frac{\pi}{2}\sum_{k=1}^{N}\left[A_k\delta_\mu(\mu-\lambda_k)\delta_\lambda(\lambda-\lambda_k) + B_k\delta_\mu(\mu+\lambda_k)\delta_\lambda(\lambda+\lambda_k)\right. \tag{11}$$
$$\left. + \frac{\epsilon^3}{|\mu|^2|\lambda|^2\bar{\mu}\bar{\lambda}}\left(\overline{A}_k\delta_{\frac{\epsilon}{\mu}}\left(\frac{\epsilon}{\mu}+\bar{\lambda}_k\right)\delta_{\frac{\epsilon}{\bar{\lambda}}}\left(\frac{\epsilon}{\lambda}+\bar{\lambda}_k\right) + \overline{B}_k\delta_{\frac{\epsilon}{\mu}}\left(\frac{\epsilon}{\mu}-\bar{\lambda}_k\right)\delta_{\frac{\epsilon}{\bar{\lambda}}}\left(\frac{\epsilon}{\lambda}-\bar{\lambda}_k\right)\right)\right]$$

containing the terms with first derivatives of delta-functions and satisfying to the reality condition $u = \overline{u}$ for the solutions have been performed by us (D.V.G. and F.I.B.) [19]. The obtained results for nonsingular and singular rational multiple pole of order two solutions u in the following two sections are stated.

3 Rational nonsingular solutions of VN equation corresponding to double pole wave functions

Let us consider at first the case of negative energies $E = -\epsilon = -|\lambda_k|^2 < 0$ in the standard representation $(-\frac{1}{4}\Delta - \widetilde{u})\psi = E\psi)$ of stationary Schrödinger equation. Some difficulties (really this is the main problem in calculations of exact solutions of VN equation) presents the fulfillment of the potentiality condition $V_2 = 0$ for the operators L_1 of the first linear auxiliary problem (5). Long calculations [19] lead in the considered case $\epsilon = |\lambda_k|^2 > 0$ to the following restrictions from potentiality on the constants A_k, B_k of the kernel R_0 (11):

$$\frac{\lambda_k^3}{B_k} - \frac{\lambda_k^3}{A_k} = \frac{i}{2}, \qquad \frac{\bar{\lambda}_k^3}{\bar{B}_k} = -\frac{\lambda_k^3}{B_k}, \qquad \frac{\bar{\lambda}_k^3}{\bar{A}_k} = -\frac{\lambda_k^3}{A_k}, \qquad k = 1,\ldots,N. \tag{12}$$

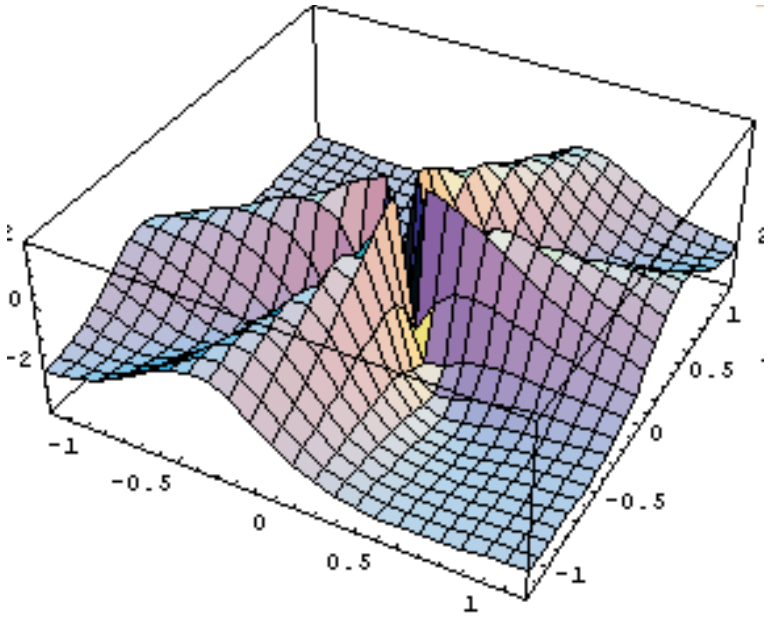

Figure 1. Nonsingular multiple order two pole rational (lump) solution of VN equation.

For the case $N = 1$ in the sum (11) under the additional condition on κ and λ_1 of the form $\kappa\lambda_1^3 = -\overline{\kappa}\overline{\lambda}_1^3$ one obtains the following exact rational nonsingular order two multiple pole solution [19] with constant asymptotic value $-\epsilon$ at infinity of VN equation (1):

$$u = -\epsilon - 32\epsilon\frac{(\lambda_R\hat{x} - \lambda_I\hat{y})^2[4(\lambda_R\hat{x} - \lambda_I\hat{y})^4 - 9(\lambda_I\hat{x} + \lambda_R\hat{y})^2]}{[4(\lambda_R\hat{x} - \lambda_I\hat{y})^4 + 3\,|\lambda_1|^2\,(\hat{x}^2 + \hat{y}^2)]^2}. \tag{13}$$

Here $\lambda_1 = \lambda_R + i\lambda_I$ and the wave variables $\hat{x}$ and $\hat{y}$ are introduced: $\hat{x} = x - V_1 t - x_0$, $\hat{y} = y - V_2 t - y_0$ with real $V_1 = 18i\frac{\lambda_I}{|\lambda_1|^2}k\lambda_1^3$, $V_2 = 18i\frac{\lambda_R}{|\lambda_1|^2}k\lambda_1^3$. This solution represents a new rational nonsingular lump, with behavior at infinity as $u \underset{|z|\to\infty}{\longrightarrow} -\epsilon + O\left(\frac{1}{|z|^2}\right)$, of VN equation propagating on the plane x, y with the velocity $\overrightarrow{V} = (V_1, V_2)$. One can see an illustration for this new lump solution of VN equation on the Fig. 1[1].

Corresponding new exact rational nonsingular potential of two-dimensional stationary Schrödinger equation (10) with multiple pole of order two wave function ψ (6) gives the formula $\widetilde{u} = u + \epsilon$ with u from (13).

4 Rational singular solutions of VN equation corresponding to double pole wave functions

Let us consider now the case of positive energies $E = -\epsilon = |\lambda_k|^2 > 0$ in the standard representation $\left(-\frac{1}{4}\Delta - \widetilde{u}\right)\psi = E\psi$ of stationary Schrödinger equation. Some difficulties (as in the previous case $\epsilon > 0$ of Section 3) presents fulfillment of the potentiality condition $V_2 = 0$ for the operators L_1 of the first linear auxiliary problem (5). Long calculations [19] in the considered case $\epsilon = -|\lambda_k|^2 < 0$ lead to the following restriction from potentiality on the constants A_k, B_k of the kernel R_0 (11):

$$\frac{\lambda_k^3}{B_k} - \frac{\lambda_k^3}{A_k} = \frac{i}{2}, \qquad \frac{\bar{\lambda}_k^3}{\bar{A}_k} = -\frac{\lambda_k^3}{B_k}, \qquad k = 1, \ldots, N. \tag{14}$$

[1]Figures in colour will be available only in electronic version.

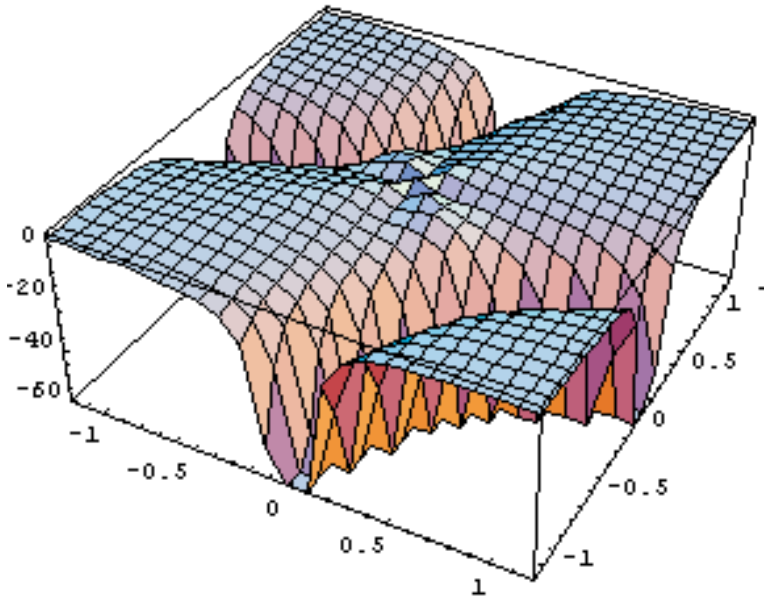

Figure 2. Singular multiple order two pole rational solution of VN equation.

For the case $N = 1$ in the sum (11) under the additional condition on κ and λ_1 of the form $\kappa\lambda_1^3 = \overline{\kappa}\overline{\lambda}_1^3$ one obtains the following exact rational singular multiple pole of order two solution with constant asymptotic value $-\epsilon$ at infinity of VN equation (1):

$$u = -\epsilon - 32\epsilon\frac{(\lambda_I\hat{x} + \lambda_R\hat{y})^2[4(\lambda_I\hat{x} + \lambda_R\hat{y})^4 + 9(\lambda_R\hat{x} - \lambda_I\hat{y})^2]}{[4(\lambda_I\hat{x} + \lambda_R\hat{y})^4 - 3\,|\lambda_1|^2\,(\hat{x}^2 + \hat{y}^2)]^2}. \tag{15}$$

Here $\lambda_1 = \lambda_R + i\lambda_I$ and the wave variables $\hat{x} = x - V_1t - x_0$, $\hat{y} = y - V_2t - y_0$ with real $V_1 = 9\frac{\lambda_R}{|\lambda_1|^2}k\lambda_1^3$, $V_2 = -9\frac{\lambda_I}{|\lambda_1|^2}k\lambda_1^3$ are introduced. The singular rational solution (15) propagates on the plane x, y with the velocity $\overrightarrow{V} = (V_1, V_2)$ One can see an illustration for this new singular rational solution of VN equation on the Fig. 2.

The corresponding new exact rational singular potential of two-dimensional stationary Schrödinger equation (10) gives the formula $\widetilde{u} = u + \epsilon$ with u from (15).

In conclusion of this note let us mention that for VN nonlinear integrable equation (1) the first auxiliary linear problem (2), i.e. two-dimensional stationary Schrödinger equation (5), is self-adjoint, but multiple pole solutions exist as the present calculations show [19]. For the KP or mKP equations the first auxiliary linear problems are non-self-adjoint, and with the non-self-adjoint character of these problems the existence of multiple pole solutions has been connected [18]. By VN equation we have the first explicit example which shows that multiple pole solutions may exist even for cases with self-adjoint first auxiliary linear problems. Our work on multiple pole rational solutions of VN equation and multiple pole rational potentials of 2DSchr equation for more general choices of kernel R_0 (8) and its parameters in general position is in progress and the results will be published elsewhere.

On N-Wave and NLS Type Systems: Generating Operators and the Gauge Group Action: the $so(5)$ Case

Vladimir S. GERDJIKOV † *and Georgi G. GRAHOVSKI* †‡

† *Institute for Nuclear Research and Nuclear Energy, Bulgarian Academy of Science, 72 Tzarigradsko chaussee, 1784 Sofia, Bulgaria*

‡ *Dipartimento di Matematica "Federigo Enriques", Università degli studi di Milano, Via C. Saldini 50, 20133 Milan, Italy*

We first review some recent developments [2] of the N-wave equations and their gauge equivalent ones related to the $so(5)$ algebra. These include the form of the equations and the relevant recursion operators, the properties of the scattering data etc. Next we generalize these results to the multicomponent nonlinear Schrödinger equations and their gauge equivalent ones known as the Heisenberg ferromagnet type equations. The explicit form of the $so(5)$ HF equations and the relevant recursion operators are derived.

1 Introduction

We start by briefly reviewing our previous results on N-wave equations and their gauge equivalent ones [1, 2] and extend them for the multicomponent NLS-type equation and their gauge equivalent.

Both classes of the above-mentioned nonlinear evolution equations (NLEE) are solvable by applying the inverse scattering method [3, 4] to the generalized Zakharov–Shabat system [5]:

$$L(\lambda)\psi \equiv \left(i\frac{d}{dx} + q(x,t) - \lambda J\right)\psi(x,t,\lambda) = 0, \tag{1}$$

related to the simple Lie algebra $\mathfrak{g}$ of rank $r > 1$. The gauge in (1) is fixed up by choosing J to be a constant element of the Cartan subalgebra $\mathfrak{h} \in \mathfrak{g}$. Then the potential $q(x,t)$ can be cast in the form $q(x,t) = [J, Q(x,t)]$, where $Q(x,t)$ is a generic element of $\mathfrak{g}$. We also assume that $q(x,t)$ tends to zero fast enough for $x \to \pm\infty$.

For the N-wave type equations J is chosen to be a regular element of $\mathfrak{h}$; as a consequence the subalgebra $\mathfrak{g}_J \subset \mathfrak{g}$ of elements commuting with J coincides with $\mathfrak{h}$. For the multi-component NLS (MNLS) type equations J as a rule is **not** a regular element of $\mathfrak{h}$ and the corresponding subalgebra $\mathfrak{g}_J$ is a non-commutative one. This makes more difficult the derivations of: i) the fundamental analytic solutions (FAS) of (1); ii) the construction of the related recursion operators and iii) the application of the gauge transformation, i.e. the transition to the pole gauge in which:

$$\tilde{L}\tilde{\psi}(x,t,\lambda) \equiv \left(i\frac{d}{dx} - \lambda\mathcal{S}(x,t)\right)\tilde{\psi}(x,t,\lambda) = 0, \tag{2}$$

$$\tilde{\psi}(x,t,\lambda) = g^{-1}(x,t)\psi(x,t,\lambda), \qquad \mathcal{S}(x,t) \equiv \mathrm{Ad}_g \cdot J = g^{-1}(x,t)Jg(x,t),$$

$$g(x,t) = \psi(x,t,\lambda=0), \qquad \text{i.e.,} \qquad \left(i\frac{d}{dx} + q(x,t)\right)g(x,t) = 0. \tag{3}$$

To be more specific let us write down the explicit form of the above mentioned NLEE along with their Lax representations and dispersion laws. The N-wave equations and their gauge

equivalent read:

$$i[J,Q_t]-i[I,Q_x]+[[I,Q],[J,Q]]=0, \tag{4}$$

$$\mathcal{S}_t-\frac{d}{dx}f(\mathcal{S})=0, \tag{5}$$

where $Q(x,t)$ is related to the potential $q(x,t)$ in (1) by $q(x,t)=[J,Q(x,t)]$. The constant regular element $I\in\mathfrak{h}$ can be expressed as a function (polynomial) of J: $I=f(J)$, see [2]. The corresponding M-operators of (4) and (5) equal:

$$M(\lambda)\psi\equiv\left(i\frac{d}{dt}+[I,Q(x,t)]-\lambda I\right)\psi(x,t,\lambda)=0, \tag{6}$$

$$\tilde{M}\tilde{\psi}(x,t,\lambda)\equiv\left(i\frac{d}{dt}-\lambda f(\mathcal{S})\right)\tilde{\psi}(x,t,\lambda)=0, \tag{7}$$

and the dispersion law for both equations is linear in λ: $f_{N-w}(\lambda)=\lambda I$. An important point here is that I and J are both regular and *linearly independent;* otherwise the corresponding equations (4) and (5) become linear.

As we mentioned above the Lax operator for the MNLS equations formally has the form (1) but now J is no more regular element of $\mathfrak{h}$. This means that the subalgebra $\mathfrak{g}_J\subset\mathfrak{g}$ of elements commuting with J (i.e., the kernel of the operator ad_J) is a non-commutative one. The dispersion law of the MNLS equation is quadratic in λ: $f_{\mathrm{MNLS}}=2\lambda^2 J$. The MNLS equation, its gauge equivalent MHF equation and their M-operators have the form:

$$i\frac{dq}{dt}+2\,\mathrm{ad}_J^{-1}\frac{d^2q}{dx^2}+[q,\pi_0[q,\mathrm{ad}_J^{-1}q]]-2i(\mathbb{1}-\pi_0)[q,\mathrm{ad}_J^{-1}q_x]=0, \tag{8}$$

$$i\frac{d\mathcal{S}}{dt}+2\frac{d}{dx}\left(\mathrm{ad}_{\mathcal{S}}^{-1}\frac{d\mathcal{S}}{dx}\right)=0, \tag{9}$$

$$M(\lambda)\psi\equiv\left(i\frac{d}{dt}-V_0^{\mathrm{d}}+2i\,\mathrm{ad}_J^{-1}q_x(x,t)+2\lambda q(x,t)-2\lambda^2 J\right)\psi(x,t,\lambda)=0, \tag{10}$$

$$\tilde{M}\tilde{\psi}(x,t,\lambda)\equiv\left(i\frac{d}{dt}-2i\lambda\,\mathrm{ad}_{\mathcal{S}}^{-1}\mathcal{S}_x-2\lambda^2\mathcal{S}\right)\tilde{\psi}(x,t,\lambda)=0, \tag{11}$$

where $V_0^d=\pi_0\left([q,\mathrm{ad}_J^{-1}q_x]\right)$ and π_0 is the projector onto $\mathfrak{g}_J$; (see also Section 3 below).

The interpretation of the inverse scattering method (ISM) as a generalized Fourier transform and the expansions over the so called "squared solutions" (see e.g. [5] for regular J and [6] for non-regular J) allows one to study all the fundamental properties of the relevant NLEE's. These include: (i) the description of the whole class NLEE related to the Lax operator $L(\lambda)$ (1) solvable by the ISM; (ii) derivation of the infinite family of integrals of motion and (iii) the Hamiltonian formulation of the NLEE's.

The "squared solutions" that appeared first in [7,8] were later generalized in [5,6] to Lax operators of the type (1); they can also be viewed as natural generalizations of the usual exponentials and are introduced by:

$$e_\alpha^{\pm}(x,t,\lambda)=(\mathbb{1}-\pi_0)\left(\chi^{\pm}(x,t,\lambda)E_\alpha\hat{\chi}^{\pm}(x,t,\lambda)\right), \tag{12}$$

where $\chi^{\pm}(x,t,\lambda)$ is the fundamental analytic solution of the Lax operator L (1). In fact their completeness relations [5,6] provide us the spectral decompositions of the operators:

$$\Lambda_+e_{\pm\alpha}^{\pm}=\lambda e_{\pm\alpha}^{\pm},\qquad \Lambda_-e_{\mp\alpha}^{\pm}=\lambda e_{\pm\alpha}^{\pm},\qquad \alpha\in\Delta_+, \tag{13}$$

known as the generating (or recursion) operators; they play crucial role in deriving the properties of the NLEE. The recursion operator appeared first in the AKNS-approach [7] as a tool to

generate the class of all M-operators as well as the NLEE related to the given Lax operator. Next I.M. Gel'fand and L.A. Dickii [9] discovered that the class of these M-operators is contained in the diagonal of the resolvent of L which could be explicitly defined in terms of the FAS $\chi^{\pm}(x,\lambda)$.

In the present paper we outline the construction of the recursion operators $\Lambda_{\pm}$ related to L (1) both for regular and non-regular elements J. In order to avoid a number of technicalities we consider only the Lax operators (1) related to the algebra $so(5)$. Our ideas, however, can be generalized to any simple Lie algebra thus allowing one to treat the corresponding class of NLEE. Another important point in our considerations is the explicit gauge covariant approach, which allows one to reformulate everything also for the pole gauge, thus extending the results in [10,6].

In Section 2 we briefly summarize our results on N-wave type equations related to $so(5)$ and their gauge equivalent, see [2, 11]. In Section 3 we resolve the technical problems in constructing the recursion operators $\Lambda_{\pm}$ for the $so(5)$ MNLS type equations by using the spectral decomposition of the operator ad_J. As a result we obtain explicit expressions for the recursion operators $\widetilde{\Lambda}_{\pm}$, gauge equivalent to $\Lambda_{\pm}$. In Section 4 we briefly show how these recursion operators generate the hierarchies of Hamiltonian structures of the MNLS equations and their gauge equivalent ones.

2 N-wave type systems and their gauge-equivalent: $so(5)$-case

The $so(5)$ algebra has two simple roots α_1, α_2 and four positive roots $\Delta_+ = \{\alpha_1, \alpha_2, \alpha_3, \alpha_4\}$ with $\alpha_1 = e_1 - e_2$, $\alpha_2 = e_2$, $\alpha_1 + \alpha_2 = e_1$, $\alpha_1 + 2\alpha_2 = e_1 + e_2$. Here we use the following parametrization for J and $q(x)$

$$q(x,t) \equiv \sum_{\alpha\in\Delta_+} (q_\alpha E_\alpha + p_\alpha E_{-\alpha}) = \begin{pmatrix} 0 & q_{10} & q_{11} & q_{12} & 0 \\ p_{10} & 0 & q_1 & 0 & q_{12} \\ p_{11} & p_1 & 0 & q_1 & -q_{11} \\ p_{12} & 0 & p_1 & 0 & q_{10} \\ 0 & p_{12} & -p_{11} & p_{10} & 0 \end{pmatrix}, \quad J = \begin{pmatrix} J_1 & 0 & 0 & 0 & 0 \\ 0 & J_2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -J_2 & 0 \\ 0 & 0 & 0 & 0 & -J_1 \end{pmatrix}, \quad (14)$$

where q_{jk} and p_{jk} are related to the roots $j\alpha_1 + k\alpha_2$ and $-j\alpha_1 - k\alpha_2$ respectively. Since in this section J is regular we can assume that $J_1 > J_2 > 0$; then the positive roots satisfy $\alpha(J) > 0$. The corresponding 4-wave system has the form [11]:

$$\begin{aligned} &i(J_1 - J_2)q_{10,t} - i(I_1 - I_2)q_{10,x} + 2\kappa q_{11}q_{01}^* = 0, \\ &iJ_2 q_{01,t} - iI_2 q_{01,x} + \kappa(q_{11}^* q_{12} + q_{11}q_{10}^*) = 0, \\ &iJ_1 q_{11,t} - iI_1 q_{11,x} + \kappa(q_{12}q_{01}^* - q_{10}q_{01}) = 0, \\ &i(J_1 + J_2)q_{12,t} - i(I_1 + I_2)q_{12,x} - 2\kappa q_{11}q_{01} = 0, \end{aligned} \quad (15)$$

where we put $p_{jk} = q_{jk}^*$, I_k are the matrix elements of $I = \mathrm{diag}\,(I_1, I_2, 0, -I_2, -I_1)$ and $\kappa = J_1 I_2 - J_2 I_1$. The system (15) can be written down as: $i\,\mathrm{ad}_J^{-1}\frac{dq}{dt} - \Lambda[I, \mathrm{ad}_J^{-1} q(x,t)] = 0$, where the recursion operators $\Lambda_{\pm}$ satisfying (13) and $\Lambda = (\Lambda_+ + \Lambda_-)/2$ are defined by:

$$\Lambda_{\pm} Z(x) = \mathrm{ad}_J^{-1}(\mathbb{1} - \pi_0)\left(i\frac{dZ}{dx} + [q(x), Z(x)] + i\left[q(x), \pi_0 \int_{\pm\infty}^{x} dy\,[q(y), Z(y)]\right]\right). \quad (16)$$

The equation (15) find an applications in nonlinear optics [3, 11], and their gauge equivalent – in differential geometry [13]. The equations, gauge equivalent to (15) are:

$$\frac{d\mathcal{S}}{dt} - f_1\frac{d\mathcal{S}}{dx} - f_3\frac{d\mathcal{S}^3}{dx} = 0, \qquad f_1 = \frac{I_2 J_1^3 - I_1 J_2^3}{J_1 J_2\left(J_1^2 - J_2^2\right)}, \qquad f_3 = \frac{I_1 J_2 - I_2 J_1}{J_1 J_2\left(J_1^2 - J_2^2\right)}, \quad (17)$$

where the matrix $\mathcal{S}(x,t) \in so(5)$ is constrained by:

$$\mathrm{tr}\,\mathcal{S}^2 = 2\left(J_1^2 + J_2^2\right), \qquad \mathrm{tr}\,\mathcal{S}^4 = 2\left(J_1^4 + J_2^4\right), \qquad \mathcal{S}\left(\mathcal{S}^2 - J_1^2\right)\left(\mathcal{S}^2 - J_2^2\right) = 0. \quad (18)$$

We are using explicitly gauge covariant approach which allows one to reformulate all fundamental properties of the NLEE to be easily reformulated from one gauge to another. In particular, the gauge-equivalent "squared solutions" and recursion operators are given by:

$$\widetilde{e}^{\pm}_{\alpha}(x,t,\lambda) = g^{-1}(x,t)e^{\pm}_{\alpha}(x,t,\lambda)g(x,t), \qquad \widetilde{\Lambda}_{\pm}\widetilde{Z} = (g^{-1}(x,t)\Lambda g(x,t))\widetilde{Z}(x,t), \tag{19}$$

where

$$\widetilde{\Lambda}_{\pm}\widetilde{Z} = i\,\mathrm{ad}^{-1}_{S(x)}(\mathbb{1}-\widetilde{\pi}_0(x))\left\{\frac{d\widetilde{Z}}{dx}+\sum_{k=1}^{2}[\widetilde{h}_k(x),\mathrm{ad}^{-1}_{\mathcal{S}(x)}]\int_{\pm\infty}^{x}dy\left\langle[\widetilde{h}_k(y),\mathrm{ad}^{-1}_{\mathcal{S}(y)}\mathcal{S}_y],\widetilde{Z}(y)\right\rangle\right\}, \tag{20}$$

where $\widetilde{h}_k(x,t) = g^{-1}(x,t)H_k g(x,t)$, $\langle H_k, H_j\rangle = \langle \widetilde{h}_k(x,t), \widetilde{h}_j(x,t)\rangle = \delta_{jk}$. The main difficulty in deriving the explicit form of the gauge equivalent equations is in the need to express all relevant quantities, such as $g^{-1}q(x,t)g(x,t)$, $g^{-1}Ig(x,t)$, etc. in terms of $\mathcal{S}$ only. The starting point is that both I and J have a common set of eigensubspaces and also the fact that if $J\in\mathfrak{h}$ then also $J^3\in\mathfrak{h}$. In what follows we express the Cartan generators $H_1 = \mathrm{diag}\,(1,0,0,0,-1)$ and $H_2 = \mathrm{diag}\,(0,1,0,-1,0)$ as polynomials of J, see [11],

$$h_1 = \frac{J}{J_1}\frac{J^2-J_2^2}{J_1^2-J_2^2}, \qquad h_2 = \frac{J}{J_2}\frac{J^2-J_1^2}{J_2^2-J_1^2}, \qquad g^{-1}(x,t)q(x,t)g(x,t) = -i\,\mathrm{ad}^{-1}_{\mathcal{S}(x)}\mathcal{S}_x, \tag{21}$$

$$\widetilde{h}_1(x,t) = \frac{\mathcal{S}}{J_1}\frac{\mathcal{S}^2-J_2^2}{J_1^2-J_2^2}, \qquad \widetilde{h}_2(x,t) = \frac{\mathcal{S}}{J_2}\frac{\mathcal{S}^2-J_1^2}{J_2^2-J_1^2}. \tag{22}$$

Thus we have $I = I_1h_1 + I_2h_2$. Applying the gauge transformation to this formula allows us to find the desired expression for $g^{-1}Ig(x,t)$ in terms of $\mathcal{S}$:

$$f(\mathcal{S}) = I_1\widetilde{h}_1(x,t) + I_2\widetilde{h}_2(x,t) = f_1\mathcal{S} + f_3\mathcal{S}^3,$$

compare with equation (17). The set of constraints on $\mathcal{S}$ come from the fact that it has constant eigenvalues equal to $\pm J_1$, $\pm J_2$ and 0. These formulas together with the set of nonlinear constraints mentioned above completely determine the NLEE's gauge equivalent to the N-wave ones. Note that the number of the independent coefficients in $\mathcal{S}$ is equal to the number of the roots of the algebra, equal to 4 in the case of $so(5)$.

One can also derive explicitly the operator inverse to $\widetilde{\Lambda}$ generalizing the result in [12]:

$$\widetilde{\Lambda}^{-1}_{\pm}\widetilde{Z} = \frac{1}{i}(\mathbb{1}-\widetilde{\pi}_0)\int_{\pm\infty}^{x}dy\,[S(y),\widetilde{Z}(y)]. \tag{23}$$

The direct scattering problem for the Lax operator (1) is based on the Jost solutions and the scattering matrix $T(\lambda)$:

$$\lim_{x\to\infty}\psi(x,\lambda)e^{i\lambda Jx} = \mathbb{1}, \qquad \lim_{x\to-\infty}\phi(x,\lambda)e^{i\lambda Jx} = \mathbb{1}, \quad T(\lambda) = (\psi(x,\lambda))^{-1}\phi(x,\lambda). \tag{24}$$

The FAS $\chi^{\pm}(x,\lambda)$ of $L(\lambda)$ are related to the Jost solutions by [3, 5, 14]

$$\chi^{\pm}(x,\lambda) = \phi(x,\lambda)S^{\pm}(\lambda) = \psi(x,\lambda)T^{\mp}(\lambda)D^{\pm}(\lambda), \tag{25}$$

where $T^{\pm}(\lambda)$ and $S^{\pm}(\lambda)$, $D^{\pm}(\lambda)$ are elements of the group $SO(5)$ and are factors in the Gauss decomposition of the scattering matrix: $T(\lambda) = T^{-}(\lambda)D^{+}(\lambda)\hat{S}^{+}(\lambda) = T^{+}(\lambda)D^{-}(\lambda)\hat{S}^{-}(\lambda)$. Here $\hat{S}\equiv S^{-1}$, $S^{\pm}(\lambda,t) = \exp\left(\sum_{\alpha\in\Delta_+}s^{\pm}_{\alpha}(\lambda,t)E_{\pm\alpha}\right)$, and similar expressions for $T^{\pm}(\lambda,t)$. In particular $D^{\pm}(\lambda) = \exp(\pm d_1^{\pm}(\lambda)H_1 \pm d_2^{\pm}(\lambda)H_2)$ are analytic functions of λ for $\mathrm{Im}\,\lambda > 0$ and $\mathrm{Im}\,\lambda < 0$ respectively.

On the real axis $\chi^+(x,\lambda)$ and $\chi^-(x,\lambda)$ are related by $\chi^+(x,\lambda) = \chi^-(x,\lambda)G_0(\lambda)$, $G_0(\lambda) = \hat{S}^-(\lambda)S^+(\lambda)$, and the function $G_0(\lambda)$ can be considered as a minimal set of scattering data in the case of absence of discrete eigenvalues of (1) [3, 14, 5].

If the potential $q(x,t)$ of $L(\lambda)$ (1) satisfies the N-wave equation (15) then $f_{N-w}(\lambda) = \lambda I$ and

$$i\frac{dS^\pm}{dt} - [f_{N-w}(\lambda), S^\pm(\lambda,t)] = 0, \qquad i\frac{dT^\pm}{dt} - [f_{N-w}(\lambda), T^\pm(\lambda,t)] = 0, \qquad \frac{dD^\pm}{dt} = 0, \tag{26}$$

i.e., $S^\pm(\lambda)$ and $T^\pm(\lambda)$ satisfy linear ODE while the coefficients $d_j^\pm(\lambda)$ are generating functional of the local integrals of motion of the NLEE.

The scattering data for the gauge equivalent equations $\tilde{S}^\pm(\lambda)$, $\tilde{T}^\pm(\lambda)$ and $\tilde{D}^\pm(\lambda)$ are related to the scattering data of the "canonical" systems as follows:

$$\tilde{S}^\pm(\lambda) = T(0)S^\pm(\lambda)\hat{T}(0), \qquad \tilde{T}^\pm(\lambda) = T^\pm(\lambda), \qquad \tilde{D}^\pm(\lambda) = D^\pm(\lambda)\hat{T}(0). \tag{27}$$

$T(0)$ is an element of the Cartan subgroup of $SO(5)$. On the real λ axis again $\tilde{G}_0(\lambda) = \hat{\tilde{S}}^-(\lambda)\tilde{S}^+(\lambda)$ can be considered as a *minimal set of scattering data* for the gauge equivalent systems.

In order to obtain the soliton solutions for the gauge equivalent N-wave systems one needs to apply the Zakharov–Shabat dressing method to a regular FAS $\tilde{\chi}^\pm_{(0)}(x,\lambda)$ of $\tilde{L}$ with potential $\mathcal{S}_{(0)}$. Thus one gets a new singular solution $\tilde{\chi}^\pm_{(1)}(x,\lambda)$ of the Riemann–Hilbert problem with singularities located at prescribed positions $\lambda_1^\pm$. It is related to the regular one by the dressing Zakharov–Shabat factors [3] $\tilde{u}(x,\lambda)$:

$$\tilde{\chi}^\pm_{(1)}(x,\lambda) = \tilde{u}(x,\lambda)\tilde{\chi}^\pm_{(0)}(x,\lambda)\tilde{u}_-^{-1}(\lambda), \qquad \tilde{u}_-(\lambda) = \lim_{x\to-\infty}\tilde{u}(x,\lambda), \tag{28}$$

and the dressing factors for the gauge equivalent equations $\tilde{u}(x,\lambda)$ are related to $u(x,\lambda)$ by

$$\tilde{u}(x,\lambda) = g_{(0)}^{-1}(x,t)u^{-1}(x,\lambda=0)u(x,\lambda)g_{(0)}. \tag{29}$$

Then the new solutions $\tilde{\chi}^\pm_{(1)}(x,\lambda)$ will correspond to a potential $\mathcal{S}_{(1)}$ of $\tilde{L}$ with two discrete eigenvalues $\lambda_1^\pm$. The explicit construction of the dressing factors is discussed in [11] for the "canonical" N-wave systems and in [2] for their gauge equivalent. Note only that getting the explicit form of the dressing factors one gets the 1-soliton solution as well. The n-soliton solutions could be obtained by multiple applying the dressing method (n-times).

3 Generating (recursion) operators for MNLS type models

The MNLS type system for has a dispersion law $f(\lambda) = 2\lambda^2 J$. Our choice for J is a degenerate one, because $\alpha_1(J) = 0$; the set of roots $\Delta_1^+ = \{\alpha_2, \alpha_3, \alpha_4\}$ of $so(5)$, for which $\alpha(J) \neq 0$ labels the coefficients of the potential $q(x,t)$:

$$q(x,t) \equiv \sum_{\alpha\in\Delta_1^+}(q_\alpha E_\alpha + p_\alpha E_{-\alpha}) = \begin{pmatrix} 0 & 0 & q_{11} & q_{12} & 0 \\ 0 & 0 & q_1 & 0 & q_{12} \\ p_{11} & p_1 & 0 & q_1 & -q_{11} \\ p_{12} & 0 & p_1 & 0 & 0 \\ 0 & p_{12} & -p_{11} & 0 & 0 \end{pmatrix}, \quad J = \begin{pmatrix} a & 0 & 0 & 0 & 0 \\ 0 & a & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -a & 0 \\ 0 & 0 & 0 & 0 & -a \end{pmatrix}, \tag{30}$$

where we assumed $p_{jk} = q_{jk}^*$. The corresponding MNLS type system is of the form:

$$i\frac{dq_{12}}{dt} + \frac{1}{2a}\frac{d^2q_{12}}{dx^2} - \frac{1}{a}q_{12}(|q_1|^2 + |q_{11}|^2 + |q_{12}|^2) + \frac{i}{a}q_1q_{11,x} - \frac{i}{a}q_{11}q_{1,x} = 0,$$

$$i\frac{dq_{11}}{dt}+\frac{1}{a}\frac{d^2q_{11}}{dx^2}-\frac{1}{a}q_{11}\left(|q_1|^2+|q_{11}|^2+\frac{1}{2}|q_{12}|^2\right)+\frac{i}{a}q_{12}q^*_{1,x}+\frac{i}{2a}q_{12,x}q^*_1=0, \tag{31}$$
$$i\frac{dq_1}{dt}+\frac{1}{a}\frac{d^2q_1}{dx^2}-\frac{1}{a}q_1\left(|q_1|^2+|q_{11}|^2+\frac{1}{2}|q_{12}|^2\right)-\frac{i}{a}q_{12}q^*_{11,x}-\frac{i}{2a}q_{12,x}q^*_{11}=0.$$

Our choice of J means that $K=\mathrm{ad}_J$ has five different eigenvalues: $-2a$, $-a$, 0, a and $2a$. Then the minimal characteristic polynomial for K is:

$$K\left(K^2-a^2\right)\left(K^2-4a^2\right)=0. \tag{32}$$

Let us also introduce the projectors onto the eigensubspaces of K as follows:

$$\pi_{\pm2}=\frac{K\left(K^2-a^2\right)(K\pm2a)}{24a^4},\qquad \pi_{\pm1}=-\frac{K\left(K^2-4a^2\right)(K\pm a)}{6a^4},$$
$$\pi_0=\frac{\left(K^2-a^2\right)\left(K^2-4a^2\right)}{4a^4}.$$

Using the characteristic equation (32) it is easy to check that π_j are orthogonal projectors; i.e. they satisfy: $\pi_j\pi_k=\delta_{jk}\pi_j$ for all $j,k=\pm2$, ±1, 0 and that $K\pi_{\pm2}=\pm2a\pi_{\pm2}$, $K\pi_{\pm1}=\pm a\pi_{\pm1}$, $K\pi_0=0$. Thus any function $f(K)$ can be expressed in terms of these projectors: $f(K)=f(2a)\pi_2+f(a)\pi_1+f(0)\pi_0+f(-a)\pi_{-1}f(-2a)\pi_{-2}$ provided $f(\lambda)$ is regular for $\lambda=\pm2a$, $\pm a$ and 0.

The phase space $\mathcal{M}_J$ of the MNLS equations is the co-adjoint orbit of the $so(5)$ determined by J; its elements are matrices $q(x,t)$ satisfying $\pi_0q(x,t)=0$. Note also that $\mathrm{ad}_J=K$ introduces a grading on $\mathfrak{g}=\overset{2}{\underset{j=-2}{\oplus}}\mathfrak{g}_j$ and the projectors π_j project precisely onto $\mathfrak{g}_j$. Obviously $\mathfrak{g}_j=\pi_j\mathfrak{g}$, $\mathfrak{g}_0\equiv\mathfrak{g}_J$ and $\mathcal{M}_J\simeq\mathfrak{g}\backslash\mathfrak{g}_J$. The "squared solutions" again have the form (12), but now the corresponding FAS and the projectors π_0 are different due to the choice of J:

$$\chi^{\pm}(x,t,\lambda)=\phi(x,t,\lambda)S^{\pm}_J(t,\lambda)=\psi(x,t,\lambda)T^{\mp}_J(t,\lambda)D^{\pm}_J(\lambda). \tag{33}$$

Here $S^{\pm}_J$, $T^{\pm}_J$ and $D^{\pm}_J$ are the factors in the generalized Gauss decompositions of $T(t,\lambda)$ [6]:

$$T(t,\lambda)=T^-_J(t,\lambda)D^+_J(\lambda)\hat{S}^+_J(t,\lambda)=T^+_J(t,\lambda)D^-_J(\lambda)\hat{S}^-_J(t,\lambda), \tag{34}$$
$$S^{\pm}_J(t,\lambda)=\exp\left(\sum_{\alpha\in\Delta^+_1}s^{\pm}_{J,\alpha}(t,\lambda)E_{\pm\alpha}\right),\qquad T^{\pm}_J(t,\lambda)=\exp\left(\sum_{\alpha\in\Delta^+_1}t^{\pm}_{J,\alpha}(t,\lambda)E_{\pm\alpha}\right), \tag{35}$$
$$D^{\pm}_J(\lambda)=\exp\left(\pm d^{\pm}_1(\lambda)H_1\pm2d^{\pm}_2(\lambda)H_2+d^{\pm}_{\alpha_1}(\lambda)E_{\alpha_1}+d^{\pm}_{-\alpha_1}(\lambda)E_{-\alpha_1}\right). \tag{36}$$

If $q(x,t)$ evolves according to the MNLS (3) then

$$i\frac{dS^{\pm}_J}{dt}-2\lambda^2[J,S^{\pm}_J(t,\lambda)]=0,\qquad i\frac{dT^{\pm}_J}{dt}-2\lambda^2[J,T^{\pm}_J(t,\lambda)]=0,\qquad \frac{dD^{\pm}_J}{dt}=0. \tag{37}$$

This means that the MNLS equation (3) has four series of integrals of motion as compared to the two series of integrals for the $so(5)$ 4-wave system. This is due to the special (degenerate) choice of the dispersion law $f_{\mathrm{MNLS}}=2\lambda^2J$. We have to remember, however, that only two of these four series are in involution, which in turn is related to the non-commutativity of the subalgebra $\mathfrak{g}_J$. As a result we get the following expression for the recursion operator:

$$\Lambda_{\pm}Z=K^{-1}(\mathbb{1}-\pi_0)\left(i\frac{dZ}{dx}+[q(x),Z(x)]+i\left[q(x),\int_{\pm\infty}^{x}dy\;\pi_0[q(y),Z(y)]\right]\right), \tag{38}$$

where we assume that $Z\in\mathcal{M}_J$, i.e. $\pi_0Z(x)=0$.

In order to evaluate the gauge equivalent recursion operator we again make use of the gauge covariant approach. First it allows one easily to recalculate the projectors on the eigensubspaces of $\mathrm{ad}_{S(x)} \equiv \widetilde{K}(x) = g_0^{-1} K g_0(x,t)$:

$$\widetilde{\pi}_{\pm 2} = \frac{\widetilde{K}(\widetilde{K}^2 - a^2)(\widetilde{K} \pm 2a)}{24a^4}, \qquad \widetilde{\pi}_{\pm 1} = -\frac{\widetilde{K}(\widetilde{K}^2 - 4a^2)(\widetilde{K} \pm a)}{6a^4},$$
$$\widetilde{\pi}_0 = \frac{(\widetilde{K}^2 - a^2)(\widetilde{K}^2 - 4a^2)}{4a^4}.$$

In particular, these formulae allow us to cast the MHF system (9) in the form:

$$iS_t - \frac{5}{4a^2}[S, S_{xx}] + \frac{1}{4a^4}\left((\mathrm{ad}_S)^3 S_x\right)_x = 0, \tag{39}$$

where $\mathcal{S}$ is constrained by $\mathcal{S}\left(\mathcal{S}^2 - a^2\right)^2 = 0$. In addition the operator $\widetilde{K}(x,t)$ satisfy the equation (32). One way to derive the explicit form of the recursion operators $\widetilde{\Lambda}_\pm$ is to apply the gauge transformation to $\Lambda_\pm$ (38). For degenerate choice of J this is more difficult due to the fact that $\mathfrak{g}_J$ is non-Abelian. Here we only provide the explicit form of the operators inverse to $\widetilde{\Lambda}_\pm$

$$\tilde{\Lambda}_\pm^{-1}\tilde{Z} = \frac{1}{i}(\mathbb{1} - \widetilde{\pi}_0)\int_{\pm\infty}^{x} dy\,[S(y), \widetilde{Z}(y)], \qquad \widetilde{\pi}_0\widetilde{Z}(x) = 0. \tag{40}$$

The scattering data for the gauge equivalent MHF equations $\tilde{S}_J^\pm(\lambda)$, $\tilde{T}_J^\pm(\lambda)$ and $\tilde{D}_J^\pm(\lambda)$ are related to the scattering data of the "canonical" systems as follows: $\tilde{S}_J^\pm(\lambda) = T_J(0) S_J^\pm(\lambda)\hat{T}_J(0)$, $\tilde{T}_J^\pm(\lambda) = T_J^\pm(\lambda)$, and $\tilde{D}_J^\pm(\lambda) = D_J^\pm(\lambda)\hat{T}_J(0)$ and $\tilde{T}_J(0)$ is an element of the subgroup $\mathcal{G}_J$ of $SO(5)$. On the real λ axis again $\tilde{G}_{J,0}(\lambda) = \hat{\tilde{S}}_J^-(\lambda)\tilde{S}_J^+(\lambda)$ can be considered as a *minimal set of scattering data* for the gauge equivalent systems.

In order to obtain the soliton solutions for the gauge equivalent MHF systems one needs to apply the Zakharov–Shabat dressing method to a regular FAS $\tilde{\chi}_{(0)}^\pm(x,\lambda)$ of $\tilde{L}$ with potential $\mathcal{S}_{(0)}$. Thus one gets a new singular solution $\tilde{\chi}_{(1)}^\pm(x,\lambda)$ of the Riemann–Hilbert problem with singularities located at prescribed positions $\lambda_1^\pm$. It is related to the regular one by the dressing factors $\tilde{u}(x,\lambda)$ whose structure is analogous to the ones presented in Section 2 above.

4 Hierarchy of Hamiltonian structures for MNLS type models

It is well known that both classes of NLEE possess hierarchies of Hamiltonian structures. The phase spaces $\mathcal{M}_J$ and $\widetilde{\mathcal{M}}_\mathcal{S}$ corresponding to the standard and the pole gauge

$$\mathcal{M}_J \equiv \{q(x,t),\ \pi_0 q(x,t) = 0\}, \qquad \widetilde{\mathcal{M}}_\mathcal{S} \equiv \{S(x,t),\ S(x,t) = g^{-1}Jg(x,t)\}, \tag{41}$$

where in addition we assume that $q(x,t)$ and $S(x,t) - J$ are smooth functions tending to zero fast enough for $|x| \to \infty$.

The hierarchies of symplectic structures defined on $\mathcal{M}_J$ and $\widetilde{\mathcal{M}_\mathcal{S}}$ are generated by the corresponding recursion operators and are given by the following families of compatible two-forms:

$$\Omega_{\mathrm{q}}^{(k)} = i\int_{-\infty}^{\infty} dx \left\langle \delta q \underset{,}{\wedge} \Lambda^k \mathrm{ad}_J^{-1}\delta q(x,t)\right\rangle, \qquad \tilde{\Omega}_\mathcal{S}^{(k)} = i\int_{-\infty}^{\infty} dx \left\langle \delta\mathcal{S} \underset{,}{\wedge} \tilde{\Lambda}^k \mathrm{ad}_\mathcal{S}^{-1}\delta\mathcal{S}(x,t)\right\rangle.$$

Note also that the gauge transformation relates nontrivialy the symplectic structures, i.e. $\Omega_{\mathrm{q}}^{(k)} \simeq \tilde{\Omega}_\mathcal{S}^{(k+2)}$ (for NLS–HFE equivalence, see [16, 10]). These two hierarchies are dynamically equivalent.

5 Discussion

Here we derived new results about the construction of the recursion operators for MNLS models and their gauge equivalent MHF systems by using the gauge covariant approach. These results can be naturally extended in several directions. First, one can apply the reduction group method [17] in order to investigate the $\mathbb{Z}_2$ and other finite order reduction of the MNLS systems thus extending the results of [11, 1] for the N-wave systems. Second, it is natural to extend these reductions also to the gauge equivalent systems (5) and (9). Such results may display additional properties of the class isoparametric hypersurfaces [13] described by the equations (17) in the framework of the $so(5)$ algebra. A third open problem is to study reductions of the gauge equivalent systems and the spectral decompositions for the relevant recursion operators.

Nonlocal Brackets and Integrable String Models

Victor D. GERSHUN

Kharkiv Institute of Physics and Technology, 1 Akademicheskaya Str., 61108 Kharkiv, Ukraine
E-mail: *gershun@kipt.kharkov.ua*

The closed string model in the background gravity field is considered as a bi-Hamiltonian system in assumption that string model is the integrable model for particular kind of the background fields. The dual nonlocal Poisson brackets (PB), depending of the background fields and of their derivatives, are obtained. The integrability condition is formulated as compatibility of the bi-Hamiltonity condition and the Jacobi identity of the dual Poisson bracket. It is shown that the dual brackets and dual Hamiltonians can be obtained from the canonical PB and from the initial Hamiltonian by imposing the second kind constraints on the initial dynamical system, on the closed string model in the constant background fields, as example. Two types of the nonlocal brackets are introduced.Constant curvature and time-dependent metrics are considered, as examples. It is shown, that the Jacobi identities for the nonlocal brackets have particular solution for the space-time coordinates, as matrix representation of the simple Lie group.

1 Introduction

The bi-Hamiltonian approach [1–3] to the integrable systems was initiated by Magri [4] for investigation of the integrability of the KdV equation.

Definition 1. A finite dimensional dynamical system with $2N$ degrees of freedom x^a, $a = 1, \ldots, 2N$ is integrable, if it is described by the set of the n integrals of motion $F_1, \ldots, F_n$ in involution under some Poisson bracket (PB)

$$\{F_i, F_k\}_{\mathrm{PB}} = 0.$$

The dynamical system is completely solvable, if $n = N$. Any integral of motion (or any linear combination of them) can be considered as the Hamiltonian $H_k = F_k$.

Definition 2. The bi-Hamiltonity condition has following form:

$$\dot{x}^a = \frac{dx^a}{dt} = \{x^a, H_1\}_1 = \cdots = \{x^a, H_N\}_N. \tag{1}$$

The hierarchy of new PB arises in this connection:

$$\{,\}_1,\ \{,\}_2,\ \ldots,\ \{,\}_N.$$

The hierarchy of new dynamical systems arises under the new time coordinates t_k.

$$\frac{dx^a}{dt_{n+k}} = \{x^a, H_n\}_{k+1} = \{x^a, H_k\}_{n+1}. \tag{2}$$

The new equations of motion describe the new dynamical systems, which are dual to the original system, with the dual set of the integrals of motion. The dual set of the integrals of motion can be obtained from the original one by the mirror transformations and by contraction of the integrals of motion algebra. Contraction of the integrals of motion algebra means that

the dynamical system belongs to the orbits of corresponding generators and describes the invariant subspace. The set of the commuting integrals of motion belongs to Cartan subalgebra of this algebra. KdV equation is one of the most interesting examples of the infinite-dimensional integrable mechanical systems with soliton solutions. We consider the dynamical systems with constraints. In this case, first-kind constraints are generators of the gauge transformations and they are integrals of motion. First-kind constraints $F_k(x^a) \approx 0$, $k = 1, 2, \ldots$ form the algebra of constraints under some PB

$$\{F_i, F_k\}_{\mathrm{PB}} = C_{ik}^l F_l \approx 0.$$

The structure functions C_{ik}^l may be functions of the phase space coordinates in general case. The second kind constraints $f_k(x^a) \approx 0$ are the representations of the first kind constraints algebra. The second kind constraints is defined by the condition

$$\{f_i, f_k\} = C_{ik} \neq 0.$$

The reversible matrix C_{ik} is not a constraint, and also it is a function of phase space coordinates. The second-kind constraints take part in deformation of the $\{,\}_{\mathrm{PB}}$ to the Dirac bracket $\{,\}_D$. As a rule, such deformation leads to nonlinear and to nonlocal brackets. The bi-Hamiltonity condition leads to the dual PB that are nonlinear and nonlocal brackets as a rule. We suppose that the dual brackets can be obtained from the initial canonical bracket under the imposition of the second kind constraints. We have applied [5–9] bi-Hamiltonity approach to the investigation of the integrability of the closed string model in the arbitrary background gravity field and antisymmetric B-field. The bi-Hamiltonity condition and the Jacobi identities for the dual brackets were considered as the integrability condition for a closed string model. They led to some restrictions on the background fields. B.A. Dubrovin and S.P. Novikov have considered the local dual PB of the similar type [10] in the application to the Hamiltonian hydrodynamical models. The PB of the hydrodynamical type for the phase coordinate functions $u^i(x,t)$ is defined by the formula

$$\{u^i(x), u^k(y)\} = g^{ik}(u(x))\frac{\partial}{\partial x}\delta(x-y) - g^{ij}\Gamma_{jl}^k(u(x))u_x^l\delta(x-y).$$

There $g_{ik}(u)$, $\Gamma_{jl}^k(u)$ are the arbitrary functions of the phase space coordinates and $u_x = \partial_x u$. The Jacobi identity is satisfied if g_{ik} is the Riemannian metric without torsion,the curvature tensor is equal to zero. The metric tensor is constant, locally. O.I. Mokhov and E.V. Ferapontov introduced the nonlocal PB [11, 12]. The Ferapontov's nonlocal PB is:

$$\begin{aligned}\{u^i(x), u^k(y)\} = {} & g^{ik}(u)\frac{\partial}{\partial x}\delta(x-y) - g^{ij}\Gamma_{jl}^k u_x^l\delta(x-y) \\ & + \omega_k^{(s)i}(u(x))u_x^j\nu(x-y)\omega_d^{(s)k}(u(y))u_y^d,\end{aligned}$$

where $\nu(x-y) = \mathrm{sgn}\,(x-y) = (\frac{d}{dx})^{-1}\delta(x-y)$. This PB was used for description of the Hamiltonian system of the hydrodynamical type. There are systems with functionals of the hydrodynamical type. The density of this functionals does not depend on the derivatives u_x^k, u_{xx}^k, ..., and Hamiltonian is also a functional of the hydrodynamical type. On the contrary to these models, the functionals of the closed string model is depended of the derivatives of the string coordinates. The plan of the paper is the following. In the second section we considered closed string model in the arbitrary background gravity field. We suppose that this model is an integrable model for some configurations of the background fields. The bi-Hamiltonity condition and the Jacobi identities for the dual PB must be a result of the integrability condition, which is restricted the possible configurations of the background fields.

2 Closed string in the background fields

The string model in the background gravity field is described by the system of equations:

$$\ddot{x}^a - x''^a + \Gamma^a_{bc}(x)(\dot{x}^b\dot{x}^c - x'^b x'^c) = 0,$$
$$g_{ab}(x)(\dot{x}^a\dot{x}^b + x'^a x'^b) = 0, \qquad g_{ab}(x)\dot{x}^a x'^b = 0,$$

where $\dot{x}^a = \frac{dx^a}{d\tau}$, $x'^a = \frac{dx^a}{d\sigma}$. We will consider the Hamiltonian formalism. The closed string in the background gravity field is described by first-kind constraints in the Hamiltonian formalism:

$$h_1 = \frac{1}{2}g^{ab}(x)p_a p_b + \frac{1}{2}g_{ab}(x)x'^a x'^b \approx 0, \qquad h_2 = p_a x'^a \approx 0, \tag{3}$$

where $a, b = 0, 1, \ldots, D-1$, $x^a(\tau,\sigma)$, $p_a(\tau,\sigma)$ are the periodical functions on σ with the period on π. The original PB are the symplectic PB

$$\{x^a(\sigma), p_b(\sigma')\}_1 = \delta^a_b\delta(\sigma-\sigma'), \{x^a(\sigma), x^b(\sigma')\}_1 = \{p_a(\sigma), p_b(\sigma')\}_1 = 0.$$

The Hamiltonian equations of motion of the closed string, in the arbitrary background gravity field under the Hamiltonian $H_1 = \int_0^\pi h_1 d\sigma$ and PB $\{\ ,\ \}_1$, are

$$\dot{x}^a = g^{ab}p_b, \qquad \dot{p}_a = g_{ab}x''^b - \frac{1}{2}\frac{\partial g^{bc}}{\partial x^a}p_b p_c - \frac{1}{2}\frac{\partial g_{bc}}{\partial x^a} + \frac{\partial g_{ac}}{\partial x^b}.$$

The dual PB are obtained from the bi-Hamiltonity condition

$$\dot{x}^a = \left\{x^a, \int_0^\pi h_1(\sigma')d\sigma'\right\}_1 = \left\{x^a, \int_0^\pi h_2(\sigma')d\sigma'\right\}_2,$$
$$\dot{p}_a = \left\{p_a, \int_0^\pi h_1(\sigma')d\sigma'\right\}_1 = \left\{p_a, \int_0^\pi h_2(\sigma')d\sigma'\right\}_2. \tag{4}$$

They have the following form:

Proposition 1.

$$\begin{aligned}\{A(\sigma), B(\sigma')\}_2 &= \frac{\partial A}{\partial x^a}\frac{\partial B}{\partial x^b}[[\omega^{ab}(\sigma)+\omega^{ab}(\sigma')]\nu(\sigma'-\sigma) + [\Phi^{ab}(\sigma)+\Phi^{ab}(\sigma')]\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma)\\
&+ [\Omega^{ab}(\sigma)+\Omega^{ab}(\sigma')]\delta(\sigma'-\sigma)] + \frac{\partial A}{\partial p_a}\frac{\partial B}{\partial p_b}[[\omega_{ab}(\sigma)+\omega_{ab}(\sigma')]\nu(\sigma'-\sigma)\\
&+ [\Phi_{ab}(\sigma)+\Phi_{ab}(\sigma')]\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma) + [\Omega_{ab}(\sigma)+\Omega_{ab}(\sigma')]\delta(\sigma'-\sigma)]\\
&+ \left[\frac{\partial A}{\partial x^a}\frac{\partial B}{\partial p_b} + \frac{\partial A}{\partial p_b}\frac{\partial B}{\partial x^a}\right][[\omega^a_b(\sigma)+\omega^a_b(\sigma')]\nu(\sigma'-\sigma) + [\Phi^a_b(\sigma)+\Phi^a_b(\sigma')]\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma)]\\
&+ \left[\frac{\partial A}{\partial x^a}\frac{\partial B}{\partial p_b} - \frac{\partial A}{\partial p_b}\frac{\partial B}{\partial x^a}\right][\Omega^a_b(\sigma)+\Omega^a_b(\sigma')]\delta(\sigma'-\sigma).\end{aligned}$$

The arbitrary functions A, B, ω, Φ, Ω are the functions of the $x^a(\sigma)$, $p_a(\sigma)$. The functions ω^{ab}, ω_{ab}, Φ^{ab}, Φ_{ab} are the symmetric functions on a, b and Ω^{ab}, Ω_{ab} are the antisymmetric functions to satisfy the condition $\{A,B\}_2 = -\{B,A\}_2$.

The equations of motion under the Hamiltonian $H_2 = \int_0^\pi h_2(\sigma')d\sigma'$ and PB $\{\ ,\ \}_2$ are

$$\begin{aligned}\dot{x}^a &= -\omega^a_b x^b + 2\omega^{ab}p_b + 2\Phi^{ab}p'_b - 2\Phi^a_b x''^b + 2\Omega^a_b x'^b - 2\Omega^{ab}p'_b\\
&+ \int_0^\pi d\sigma'\left[\omega^a_b x'^a + \frac{d\omega^{ab}}{d\sigma'}p_b\right]\nu(\sigma'-\sigma) + \frac{d\Phi^{ab}}{d\sigma}p'_b - \frac{d\Phi^a_b}{d\sigma}x'^b,\end{aligned}$$

$$\dot{p}_a = -\omega_{ab}x^b - 2\Phi_{ab}x''^b + 2\Omega_{ab}x'^b + 2\omega_a^b p_b + 2\Phi_a^b p_b'' + 2\Omega_a^b p_b' + \int_0^\pi d\sigma' \left[\omega_{ab}x'^b + \frac{d\omega_a^b}{d\sigma'}p_b\right]\nu(\sigma'-\sigma) - \frac{d\Phi_{ab}}{d\sigma}x'^b + \frac{d\Phi_a^b}{d\sigma}p_b'.$$

The bi-Hamiltonity condition (4) is led to the two constraints

$$-\omega_b^a x^b + 2\omega^{ab}p_b + 2\Phi^{ab}p_b'' - -2\Phi_b^a x''^b + 2\Omega_b^a x'^b - 2\Omega^{ab}p_b' + \int_0^\pi d\sigma' \left[\omega_b^a x'^a + \frac{d\omega^{ab}}{d\sigma'}p_b\right]\nu(\sigma'-\sigma) + \frac{d\Phi^{ab}}{d\sigma}p_b' - \frac{d\Phi_b^a}{d\sigma}x'^b = g^{ab}p_b,$$

$$-\omega_{ab}x^b - 2\Phi_{ab}x''^b + 2\Omega_{ab}x'^b + 2\omega_a^b p_b + 2\Phi_a^b p_b'' + 2\Omega_a^b p_b' + \int_0^\pi d\sigma' \left[\omega_{ab}x'^b + \frac{d\omega_a^b}{d\sigma'}p_b\right]\nu(\sigma'-\sigma) - \frac{d\Phi_{ab}}{d\sigma}x'^b + \frac{d\Phi_a^b}{d\sigma}p_b' = g_{ab}x''^b - \frac{1}{2}\frac{\partial g^{bc}}{\partial x^a}p_b p_c - \frac{1}{2}\frac{\partial g_{bc}}{\partial x^a}x'^b x'^c + \frac{\partial g_{ac}}{\partial x^b}x'^b x'^c.$$

In reality, there is the list of the constraints depending on the possible choice of the unknown functions ω, Ω, Φ. In the general case, there are both the first-kind constraints and the second-kind constraints too. Also it is possible to solve the constraints equations as the equations for the definition of the functions ω, Φ, Ω. We considered the latter possibility and we obtained the following consistent solution of the bi-Hamiltonity condition:

$$\Phi^{ab} = 0, \qquad \Omega^{ab} = 0, \qquad \Phi_b^a = 0, \qquad \Omega_b^a = 0, \qquad \frac{\partial\omega^{ab}}{\partial x^c}x^c + 2\omega^{ab} = g^{ab},$$

$$\omega_{ab} = \frac{1}{2}\frac{\partial^2\omega^{cd}}{\partial x^a\partial x^b}p_c p_d, \qquad \omega_b^a = -\frac{\partial\omega^{ac}}{\partial x^b}p_c,$$

$$\Phi_{ab} = -\frac{1}{2}g_{ab}, \qquad \Omega_{ab} = \frac{1}{2}\left(\frac{\partial\Phi_{bc}}{\partial x^a} - \frac{\partial\Phi_{ac}}{\partial x^b}\right)x'^c, \qquad \frac{\partial\omega^{ab}}{\partial p_c} = 0.$$

Remark 1. In distinct from the PB of the hydrodynamical type, we need to introduce the separate PB for the coordinates of the Minkowski space and for the momenta because, the gravity field is not depend of the momenta. Although, this difference is vanished under the such constraint as $f(x^a, p_a) \approx 0$.

Consequently, the dual PB for the phase space coordinates are

$$\{x^a(\sigma), x^b(\sigma')\}_2 = [\omega^{ab}(\sigma) + \omega^{ab}(\sigma')]\nu(\sigma'-\sigma),$$

$$\{p_a(\sigma), p_b(\sigma')\}_2 = \left[\frac{\partial^2\omega_{cd}(\sigma)}{\partial x^a\partial x^b}p_c p_d + \frac{\partial^2\omega_{cd}(\sigma')}{\partial x^a\partial x^b}p_c p_d\right]\nu(\sigma'-\sigma) - \frac{1}{2}[g_{ab}(\sigma) + g_{ab}(\sigma')]\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma) + \left[\frac{\partial g_{ac}}{\partial x^b} - \frac{\partial g_{bc}}{\partial x^a}\right]x'^c(\sigma)\delta(\sigma'-\sigma),$$

$$\{x^a(\sigma), p_b(\sigma')\}_2 = -\left[\frac{\partial\omega^{ac}(\sigma)}{\partial x^b}p_c + \frac{\partial\omega^{ac}(\sigma')}{\partial x^b}p_c\right]\nu(\sigma'-\sigma),$$

$$\{p_a(\sigma), x^b(\sigma')\}_2 = -\left[\frac{\partial\omega^{bc}(\sigma)}{\partial x^a}p_c + \frac{\partial\omega^{bc}(\sigma')}{\partial x^c}p_c\right]\nu(\sigma'-\sigma). \tag{5}$$

The function $\omega^{ab}(x)$ is satisfied on the equation:

$$\frac{\partial\omega^{ab}}{\partial x^c}x^c + 2\omega^{ab} = g^{ab}. \tag{6}$$

The Jacobi identities for the PB $\{\,,\,\}_2$ are led to the nonlocal consistence conditions on the unknown function $\omega^{ab}(\sigma)$. We can calculate unknown metric tensor $g^{ab}(\sigma)$ by substitution of the solution of the consistence condition for ω^{ab} to the equation (6). The Jacobi identity

$$\{x^a(\sigma), x^b(\sigma')\}x^c(\sigma'')\}_J \\ \equiv \{x^a(\sigma), x^b(\sigma')\}x^c(\sigma'')\} + \{x^c(\sigma''), x^a(\sigma)\}x^b(\sigma')\} + \{x^b(\sigma'), x^c(\sigma'')\}x^a(\sigma)\} = 0 \quad (7)$$

is led to the following nonlocal analogy of the WDVV consistence condition:

$$\left[\frac{\partial\omega^{ab}(\sigma)}{\partial x^d}[\omega^{dc}(\sigma)+\omega^{dc}(\sigma'')] - \frac{\partial\omega^{ac}(\sigma)}{\partial x^d}[\omega^{db}(\sigma)+\omega^{db}(\sigma')]\right]\nu(\sigma'-\sigma)\nu(\sigma''-\sigma) \quad (8)$$
$$+\left[\frac{\partial\omega^{cb}(\sigma')}{\partial x^d}[\omega^{da}(\sigma')+\omega^{da}(\sigma)] - \frac{\partial\omega^{ab}(\sigma')}{\partial x^d}[\omega^{dc}(\sigma')+\omega^{dc}(\sigma'')]\right]\nu(\sigma-\sigma')\nu(\sigma''-\sigma')$$
$$+\left[\frac{\partial\omega^{ac}(\sigma'')}{\partial x^d}[\omega^{db}(\sigma'')+\omega^{db}(\sigma')] - \frac{\partial\omega^{cb}(\sigma'')}{\partial x^d}[\omega^{da}(\sigma'')+\omega^{da}(\sigma)]\right]\nu(\sigma-\sigma'')\nu(\sigma'-\sigma'')=0.$$

This equation has the particular solution of the following form:

$$\frac{\partial\omega^{ab}(\sigma)}{\partial x^d}[\omega^{dc}(\sigma)+\omega^{dc}(\sigma'')] - \frac{\partial\omega^{ac}(\sigma)}{\partial x^d}[\omega^{db}(\sigma)+\omega^{db}(\sigma')] \\ = [T^b,T^c]T^a]f(\sigma,\sigma',\sigma'')\nu(\sigma''-\sigma)\nu(\sigma'-\sigma). \quad (9)$$

T^a, $a=0,1,\ldots,D-1$, is the matrix representation of the simple Lie algebra and $f(\sigma,\sigma',\sigma'')$ is arbitrary function. The Jacobi identity is satisfied on the Jacobi identity of the simple Lie algebra in this case:

$$([T^a,T^b]T^c] + [T^c,T^a]T^b] + [T^b,T^c]T^a])f(\sigma,\sigma',\sigma'') = 0$$

and we used the relation $\nu^2(\sigma-\sigma')=1$. The local solution of the Jacobi identities is led to the constant metric tensor. The rest Jacobi identities are cumbrous and we do not reduce this expressions here. The symmetric factor of σ, σ' of the antisymmetric functions $\nu(\sigma'-\sigma)$, $\frac{\partial}{\partial\sigma}\delta(\sigma-\sigma')$ in the right side of the PB can be both sum of the functions of σ and σ', and production of them. Last possibility can be used in the vielbein formalism.

Proposition 2. *The bi-Hamiltonity condition can be solved in the terms PB $\{\,,\,\}_2$, which have the following form:*

$$\{x^a(\sigma),x^b(\sigma')\}_2 = e^a_\mu(\sigma)e^b_\mu(\sigma')\nu(\sigma'-\sigma),$$
$$\{x^a(\sigma),p_b(\sigma'\}_2 = -e^a_\mu(\sigma)\frac{\partial e^c_\mu(\sigma'}{\partial x^b}p_c(\sigma')\nu(\sigma'-\sigma),$$
$$\{p_a(\sigma),p_b(\sigma')\}_2 = \frac{\partial e^c_\mu(\sigma)}{\partial x^a}p_c(\sigma)\frac{\partial e^d_\mu(\sigma')}{\partial x^b}p_d(\sigma')\nu(\sigma'-\sigma) - e^\mu_a(\sigma)e^\mu_b(\sigma')\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma)$$
$$+\left[\frac{\partial e^\mu_a}{\partial x^c}e^\mu_b - \frac{\partial e^\mu_b}{\partial x^c}e^\mu_a - \frac{\partial e^\mu_c}{\partial x^a}e^\mu_b + \frac{\partial e^\mu_c}{\partial x^b}e^\mu_a\right]x'^c(\sigma)\delta(\sigma'-\sigma), \quad (10)$$

where veilbein e^a_μ is satisfied on the additional conditions:

$$g^{ab} = \eta^{\mu\nu}e^a_\mu e^b_\nu, \qquad g_{ab} = \eta_{\mu\nu}e^\mu_a e^\nu_b$$

and $\eta^{\mu\nu}$ is the metric tensor of the flat space.

The particular solution of the Jacobi identity is

$$\frac{\partial e^a_\mu(\sigma)}{\partial x^d} e^b_\mu(\sigma') e^d_\nu(\sigma) e^c_\nu(\sigma'') - \frac{\partial e^a_\mu(\sigma)}{\partial x^d} e^c_{mu}(\sigma'') e^d_\nu(\sigma) e^b_\nu(\sigma') = [T^b, T^c]T^a] f(\sigma, \sigma', \sigma'')\nu(\sigma'' - \sigma)\nu(\sigma' - \sigma). \tag{11}$$

As example let me consider the the constant curvature space.

Example 1. The constant curvature space is described by the metric tensor $g_{ab}(x(\sigma))$ and by it inverse tensor g^{-1}_{ab}:

$$g_{ab} = \eta_{ab} + \frac{k x_a x_b}{1 - kx^2}, \qquad g^{ab} \equiv g^{-1}_{ab} = \eta_{ab} - k x_a x_b.$$

Proposition 3. *Dual PB* $\{\,,\,\}_2$ *are:*

$$\begin{aligned}
&\{x_a(\sigma), x_b(\sigma')\} = [\eta_{ab} - k x_a(\sigma) x_b(\sigma')]\nu(\sigma' - \sigma),\\
&\{x_a(\sigma), p_b(\sigma')\} = k x_a(\sigma) p_b(\sigma')\nu(\sigma' - \sigma),\\
&\{p_a(\sigma), p_b(\sigma')\} = -k p_a(\sigma) p_b(\sigma')\nu(\sigma' - \sigma)\\
&\quad - \frac{1}{2}\left[2\eta_{ab} + \frac{k x_a x_b}{1 - kx^2}(\sigma) + \frac{k x_a x_b}{1 - kx^2}(\sigma')\right] \frac{\partial}{\partial \sigma'}\delta(\sigma' - \sigma) + \frac{x_a x'_b - x_b x'_a}{2(1 - kx^2)}\delta(\sigma' - \sigma).
\end{aligned} \tag{12}$$

The Jacobi identity (7) is led to the equation

$$\begin{aligned}
&[\eta_{ab} x_c(\sigma'') - \eta_{ac} x_b(\sigma')]\nu(\sigma' - \sigma)\nu(\sigma - \sigma'') + [\eta_{bc} x_a(\sigma) - \eta_{ba} x_c(\sigma'')]\nu(\sigma - \sigma')\nu(\sigma' - \sigma'')\\
&\quad + [\eta_{ca} x_b(\sigma') - \eta_{cb} x_a(\sigma)]\nu(\sigma' - \sigma'')\nu(\sigma'' - \sigma) = 0.
\end{aligned}$$

The particular solution of this equation is:

$$\eta_{ab} x_c(\sigma'') - \eta_{ac} x_b(\sigma') = [T_b, T_c]T_a] f(\sigma, \sigma', \sigma'')\nu(\sigma'' - \sigma)\nu(\sigma' - \sigma). \tag{13}$$

Consequently, the space-time coordinate $x_a(\sigma)$ is the matrix representation of the simple Lie algebra. The Jacobi identity $\{x_a(\sigma), x_b(\sigma')\}p_c(\sigma'')\}_J$ is led to the equation

$$k\eta_{ab} p_c(\sigma'')\nu(\sigma' - \sigma)[\nu(\sigma'' - \sigma) + \nu(\sigma'' - \sigma')] = 0. \tag{14}$$

These results can be obtained from the veilbein formalism under the following ansatz for the veilbein of the constant curvature space:

$$e^{a(s)}_\mu = n_\mu\big(m^{(s)}_1 n^a + \sqrt{k} m^{(s)}_2 x^a\big), \qquad e^{\mu(s)}_a = n^\mu g_{ab}\big(m^{(s)}_1 n^b + \sqrt{k} m^{(s)}_2 x^b\big),$$

where $n^2_\mu = 1$, $m^{(s)}_1 m^{(s)}_1 = 1$, $m^{(s)}_2 m^{(s)}_2 = -1$, $m^{(s)}_1 m^{(s)}_2 = 0$, $n^a n^b = \delta^{ab}$ and (s) is number of the solution of the equations

$$e^a_\mu e^b_\mu = g^{ab}, \qquad e^\mu_a e^\mu_b = g_{ab}, \qquad e^a_\mu e^\mu_b = \delta^a_b.$$

The following example is time-dependent metric space.

Example 2. The time-dependent metric in the light-cone variables has form:

$$ds^2 = g_{ik}(x^+) dx^i dx^k + g_{++}(x^+) dx^+ dx^+ + 2 g_{+-} dx^+ dx^-.$$

We are used Poisson brackets (5) for the space coordinates $x^a = \{x^i, x^+, x^-\}$, $i = 1, 2, \ldots, D-2$. We introduced the light-cone gauge as two first kind constraints:

$$F_1(\sigma) = x'^+ \approx 0, \qquad F_2(\sigma) = p'_- \approx 0,$$

and we imposed them on the equations of motion and on the Jacobi identities. The Jacobi identities are reduced to the simple equation

$$\frac{\partial\omega^{ab}}{\partial x^+}\omega^{+c} - \frac{\partial\omega^{ac}}{\partial x^+}\omega^{+b} = 0.$$

We obtained following result from this equation and additional condition (6): there is constant background gravity field only for the non-degenerate metric.

2.1 Constant background fields

In this subsection we are supplemented the bi-Hamiltonity condition (4) by the mirror transformations of the integrals of motion.

$$\dot{x}^a = \left\{x^a, \int_0^\pi h_1 d\sigma\right\}_1 = \left\{x^a, \int_0^\pi \pm h_2 d\sigma'\right\}_{\pm 2}.$$

The dual PB are

$$\{x^a(\sigma), x^b(\sigma')\}_{\pm 2} = \pm g^{ab}\nu(\sigma'-\sigma), \qquad \{x^a(\sigma), p_b(\sigma')\}_{\pm 2} = 0,$$
$$\{p_a(\sigma), p_b(\sigma')\}_{\pm 2} = \mp\frac{1}{2} g_{ab}\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma).$$

The dual dynamical system

$$\dot{x}^a = \{x^a, \pm H_2\}_1 = \{x^a, H_1\}_{\pm 2}.$$

is the left(right) chiral string

$$\dot{x}^a = \pm x'^a, \qquad \dot{p}_a = \pm p_a'.$$

In the terms of the Virasoro operators

$$L_k = \frac{1}{4\pi}\int_0^\pi (h_1+h_2)e^{ik\sigma}d\sigma, \qquad \bar{L}_k = \frac{1}{4\pi}\int_0^\pi (h_1-h_2)e^{ik\sigma}d\sigma,$$

the first kind constraints form the Vir $\oplus$ Vir algebra under the PB $\{\,,\,\}_1$.

$$\{L_n, L_m\}_1 = -i(n-m)L_{n+m}, \qquad \{\bar{L}_n, \bar{L}_m\}_1 = -i(n-m)\bar{L}_{n+m}, \qquad \{L_n, \bar{L}_m\}_1 = 0.$$

The dual set of the integrals of motion is obtained from initial it by the mirror transformations

$$H_1 \to \pm H_2, \qquad L_0 \to \pm L_o, \qquad \bar{L}_0 \to \mp\bar{L}_0, \qquad \tau \to \sigma.$$

and by the contraction of the first kind constraints algebra $L_n = 0$, or $\bar{L}_n = 0$, $n \neq 0$. Another way to obtain the dual brackets is the imposition of the second kind constraints on the initial dynamical system, by such manner, that $F_i = F_k$ for $i \neq k$, $i,k = 1,2,\ldots$ on the constraints surface $f(x^a, p_a) = 0$. The constraints $f_a^{(-)}(x,p) = p_a - g_{ab}x'^b \approx 0$ or $f_a^{(+)} = p_a + g_{ab}x'^b \approx 0$ (do not simultaneously) are the second kind constraints.

$$\{f_a^{(\pm)}(\sigma), f_b^{(\pm)}(\sigma')\}_1 = C_{ab}^{(\pm)}(\sigma-\sigma') = \pm 2 g_{ab}\frac{\partial}{\partial\sigma'}\delta(\sigma'-\sigma).$$

The inverse matrix $(C^{(\pm)})^{-1}$ has following form $C^{(\pm)ab}(\sigma-\sigma') = \pm\frac{1}{2}g^{ab}\nu(\sigma'-\sigma)$. There is only one set of the constraints, because consistency condition

$$\{f^{(\pm)}(\sigma), H_1\}_1 = f'^{(\pm)}(\sigma) \approx 0, \quad \ldots, \quad \{f^{(\pm)(n)}(\sigma), H_1\}_1 = f^{(\pm)(n+1)}(\sigma) \approx 0.$$

is not produce the new sets of constraints. By using the standard definition of the Dirac bracket, we are obtained following Dirac brackets for the phase space coordinates

$$\{x^a(\sigma), x^b(\sigma')\}_D = \pm\frac{1}{2}g^{ab}\nu(\sigma'-\sigma), \qquad \{p_a(\sigma), p_b(\sigma')\}_D = \mp\frac{1}{2}g_{ab}\frac{\partial}{\sigma'}\delta(\sigma'-\sigma),$$
$$\{x^a(\sigma), p_b(\sigma')\}_D = \frac{1}{2}\delta^a_b\delta(\sigma'-\sigma).$$

The equations of motion under the Hamiltonians $H_1 = h_1$, $H_2 = h_2$ and Dirac bracket

$$\dot{x}^a = \{x^a, H_1\}_D = \{x^a, H_2\}_D = g^{ab}p_b = \pm x'^a,$$
$$\dot{p}_a = \{p_a, H_1\}_D = \{p_a, H_2\}_D = g_{ab}x'^b = \pm p'_a.$$

are coincide on the constraints surface. The dual brackets $\{\ ,\ \}_{\pm 2}$ are coincide with the Dirac brackets also. The contraction of the algebra of the first kind constraints means that the integrals of motion $H_1 = H_2$ are coincide on the constraints surface too.

We study an extension of integrable equations which possess the Lax representations to noncommutative spaces. We construct various noncommutative Lax equations by Lax-pair generating technique and Sato theory. Sato theory has revealed essential aspects of the integrability of commutative soliton equations and the noncommutative extension is worth studying. We succeed in deriving various noncommutative hierarchy equations in the framework of Sato theory, which is brand-new. The existence of the hierarchy would suggest a hidden infinite-dimensional symmetry in the noncommutative Lax equations. We finally show that a noncommutative version of Burgers equation is completely integrable because it is linearizable via noncommutative Cole–Hopf transformation. These results are expected to lead to the completion of noncommutative Sato theory.

1 Introduction

The extension of ordinary integrable systems to noncommutative (NC) spaces is one of hot topics in the recent study of integrable systems [1–26]. NC extension in gauge theories corresponds to the presence of background magnetic fields and leads to the discovery of many new physical objects and successful applications to string theories [27]. In particular, NC (anti-)self-dual Yang–Mills (YM) equations are integrable and important [28].

On the other hand, many typical integrable equations such as the Korteweg–de Vries (KdV) equation contain no gauge field and the NC extension of them perhaps might have no physical picture. NC extension of $(1+1)$-dimensional nonlinear equations introduces infinite number of time derivatives and it becomes very hard to define the integrability. Nevertheless, some of them actually possess integrable properties, such as the existence of infinite number of conserved quantities [3, 14]. Furthermore, a few of them can be derived from NC (anti-)self-dual YM equations by suitable reductions [8, 24]. This fact may give some physical meanings and good properties to the lower-dimensional NC field equations. Now it is time to study in detail whether they are actually integrable or not.

In this article, we present various NC equations which possess the Lax representations. We mainly discuss the Lax-pair generating technique and applications of Sato theory. Sato theory is one of the most beautiful soliton theories and reveals various integrable aspects of soliton equations, such as the existence of multi-soliton solutions, the structure of the solution space and the hidden symmetry of them. Hence NC extension of Sato theory is worth studying and the present discussions on it are all new. Here we prove the existence of various NC hierarchy equations, which would suggest hidden infinite-dimensional symmetries of NC equations. Finally we discuss the integrability of NC $(1+1)$-dimensional Burgers equation and prove that it is completely integrable due to the linearizability.

2 Noncommutative field equations

NC spaces are defined by the noncommutativity of the coordinates: $[x^i, x^j] = i\theta^{ij}$, where θ^{ij} are real constants and are called the *NC parameters*. NC field theories can be defined by replacement of ordinary products of fields in the commutative theories with the *star-product*. The star-product is defined for ordinary fields on commutative spaces and explicitly given by

$$f \star g(x) := \exp\left(\frac{i}{2}\theta^{ij}\partial_i^{(x')}\partial_j^{(x'')}\right) f(x')g(x'')\Big|_{x'=x''=x}, \tag{1}$$

where $\partial_i^{(x')} := \partial/\partial x'^i$ and so on. The star-product has associativity: $f \star (g \star h) = (f \star g) \star h$ and returns to the ordinary product in the commutative limit: $\theta^{ij} \to 0$. The modification of the product makes the ordinary spatial coordinate "noncommutative", that is, $[x^i, x^j]_\star := x^i \star x^j - x^j \star x^i = i\theta^{ij}$.

We note that the fields themselves take c-number values as usual and the differentiation and the integration for them are well-defined as usual. A nontrivial point is that NC field equations contain infinite number of derivatives in the nonlinear terms. Hence the integrability of the equations is not so trivial as in commutative cases. For detailed discussion on it, see [24].

3 Noncommutative Lax equations

A given NC differential equation is said to have the Lax representation if there exists a suitable pair of operators (L, B) so that the following equation:

$$[\partial_t - B, L]_\star = 0, \tag{2}$$

is equivalent to the given NC differential equation. Here the star-product does not affect the derivative operator, for example, $\partial_t \star \partial_x = \partial_t \partial_x$. The pair of operators (L, B) and the equation (2) are called the *Lax pair* and the *NC Lax equation*, respectively.

On NC spaces, the meaning of Lax representations would be vague [24]. However, they actually have close connections with the bi-complex method [2] which leads to infinite number of conserved quantities, and the (anti)-self-dual YM equation which is integrable in the context of twistor descriptions and ADHM constructions [28].

Now let us construct NC Lax equations by the *Lax-pair generating technique*. The technique is a method to find a corresponding B-operator for a given L-operator and based on the following ansatz for the B-operator:

$$B = \partial_i^n L^m + B'. \tag{3}$$

Then the problem reduces to that for the B'-operator which is determined by hand so that the Lax equation should be a differential equation without bare differential ∂_i.

In order to explain the steps, for example, let us consider the KdV equation on NC $(1+1)$-dimensional space-time where the coordinate and the noncommutativity are denoted by (x, t) and $[t, x] = i\theta$, respectively.

NC KdV equation [3, 8, 17, 21]. The L-operator for KdV equation is given by $L_{\rm KdV} = \partial_x^2 + u(x,t)$. The ansatz for the operator B is of the following type:

$$B_{\rm KdV} = \partial_x L_{\rm KdV} + B' = \partial_x^3 + u\partial_x + u_x + B', \tag{4}$$

where $u_x := \partial u/\partial x$. The Lax equation (2) leads to the equation for the unknown operator B':

$$[\partial_x^2 + u, B'] = u_x\partial_x^2 + u_x \star u - u_t. \tag{5}$$

Here the bare derivative term $u_x\partial_x^2$ is troublesome. In order to eliminate it, let us take the following ansatz for B': $B' = X\partial_x + Y$, where X and Y are polynomial of $u, u_x, u_t, u_{xx} := \partial^2 u/\partial x^2$ etc. The Lax equation (2) reduces to

$$(2X-u)_x\partial_x^2 + (X_{xx} + [u,X] + 2Y_x)\partial_x + (Y_{xx} + [u,Y] - X\star u_x + u_t - u_x\star u) = 0. \tag{6}$$

The condition that the coefficients of ∂_x^2 and ∂_x should vanish yields differential equations for X and Y, which are easily solved by $X = \frac{1}{2}u$, $Y = -\frac{1}{4}u_x$. Now the Lax equation (2) becomes a differential equation, that is, the NC KdV equation:

$$u_t = \frac{1}{4}u_{xxx} + \frac{3}{4}(u\star u)_x, \tag{7}$$

where $(u\star u)_x := u_x\star u + u\star u_x$. The nonlinear term becomes symmetric and the equation shows just a conservation law. In the star-product formalism, the spatial integration is well-defined. Hence the spatial integrations of current densities are conserved quantities as in commutative cases [24]. Here $Q := \int dx u$ is conserved, that is, $\partial_t Q = 0$.

In this way, we can generate a wide class of Lax equations on NC (2+1) and (1+1)-dimensional space-times. In particular, this method is suitable for higher-dimensional extension both on commutative spaces [29] and NC spaces [17]. Here we present some results of (2+1)-dimensional NC Lax equations where the coordinate is denoted by (x,y,t). The noncommutativity is basically introduced in space-space directions: $[x,y] = i\theta$. For more discussions and examples, see [17,21].

NC Kadomtsev–Petviashvili (KP) equation [11, 17, 21]

$$u_t = \frac{1}{4}u_{xxx} + \frac{3}{4}(u\star u)_x + \frac{3}{4}\partial_x^{-1}u_{yy} + \frac{3}{4}\big[u, \partial_x^{-1}u_y\big]_\star, \tag{8}$$

where $\partial_x^{-1}f(x) := \int^x dx' f(x')$. The Lax pair is given by

$$\begin{aligned} L_{\rm KP} &= \partial_x^2 + u(x,y,t) + \partial_y =: L'_{\rm KP} + \partial_y, \\ B_{\rm KP} &= \partial_x L'_{\rm KP} + X\partial_x + Y = \partial_x^3 + \frac{3}{2}u\partial_x + \frac{3}{4}u_x - \frac{3}{4}\partial_x^{-1}u_y. \end{aligned} \tag{9}$$

There is seen to be a nontrivial deformed term $[u, \partial_x^{-1}u_y]_\star$ in the equation (8), which vanishes in the commutative limit.

NC Bogoyavlenski–Calogero–Schiff (BCS) equation [17, 21]

$$u_t = \frac{1}{4}u_{xxy} + \frac{1}{2}(u\star u)_y + \frac{1}{4}u_x\star(\partial_x^{-1}u_y) + \frac{1}{4}(\partial_x^{-1}u_y)\star u_x + \frac{1}{4}[u, \partial_x^{-1}[u, \partial_x^{-1}u_y]_\star]_\star, \tag{10}$$

whose Lax pair and the ansatz are

$$\begin{aligned} L_{\rm BCS} &= \partial_x^2 + u(x,y,t), \\ B_{\rm BCS} &= \partial_y L_{\rm BCS} + X\partial_x + Y = \partial_x^2\partial_y + u\partial_y + \frac{1}{2}(\partial_x^{-1}u_y)\partial_x + \frac{3}{4}u_y - \frac{1}{4}\partial_x^{-1}[u, \partial_x^{-1}u_y]_\star. \end{aligned} \tag{11}$$

This time, a nontrivial term is found even in the B-operator. In commutative limit, this coincides with the BCS equation which has multi-soliton solutions [30].

4 Noncommutative hierarchy equations and Sato theory

In this section, we derive various noncommutative hierarchy equations in the framework of Sato theory [31] introducing the pseudo-differential operator.

Let us introduce the following Lax operator as a (first-order) pseudo-differential operator:

$$L = \partial_x + u_2\partial_x^{-1} + u_3\partial_x^{-2} + u_4\partial_x^{-3} + \cdots, \qquad u_k = u_k(t_1, t_2, t_3, \ldots). \tag{12}$$

The action of the operator ∂_x^n on a multiplicity operator f is given by

$$\partial_x^n \cdot f := \sum_{i\geq 0} \left(\begin{array}{c} n \\ i \end{array} \right) (\partial_x^i f)\partial^{n-i} := \sum_{i\geq 0} \frac{n(n-1)\cdots(n-i+1)}{i(i-1)\cdots 1}(\partial_x^i f)\partial^{n-i}. \tag{13}$$

We note that the definition can be extended to negative n. The examples are,

$$\begin{aligned}
&\partial_x^{-1} \cdot f = f\partial_x^{-1} - f_x\partial_x^{-2} + f_{xx}\partial_x^{-3} - \cdots, \\
&\partial_x^{-2} \cdot f = f\partial_x^{-2} - 2f_x\partial_x^{-3} + 3f_{xx}\partial_x^{-4} - \cdots, \\
&\partial_x^{-3} \cdot f = f\partial_x^{-3} - 3f_x\partial_x^{-4} + 6f_{xx}\partial_x^{-5} - \cdots,
\end{aligned}$$

where ∂_x^{-1} in the RHS acts as an integration operator $\int^x dx$. Products of pseudo-differential operators are also well-defined and the total set of pseudo-differential operators forms an operator algebra. For more on pseudo-differential operators and Sato theory, see e.g. [32].

The Lax representation for a hierarchy in Sato's framework is defined as

$$[\partial_{t_m} - B_m, L]_\star = 0, \qquad m = 1, 2, \ldots, \tag{14}$$

where B_m is given here by

$$B_m := (\underbrace{L \star \cdots \star L}_{m \text{ times}})_{\geq 0} =: (L^m)_{\star \geq 0}. \tag{15}$$

The suffix "≥ 0" represents the positive and 0-th power part of L^m. The examples are

$$B_1 = \partial_x, \quad B_2 = \partial_x^2 + 2u_2, \quad B_3 = \partial_x^3 + 3u_2\partial_x + 3(u_3 + u_{2x}), \quad \ldots. \tag{16}$$

The noncommutativity is introduced for infinite number of "time variables" $(t_1, t_2, \ldots)$. As it can be taken arbitrarily, we do not fix the noncommutativity here.

NC KP hierarchy. The hierarchy (14) gives rise to NC KP hierarchy which contains the NC KP equation (8). The coefficients of each powers of (pseudo-)differential operators yield infinite series of NC "evolution equations", that is, for $m = 1$

$$\partial_x^{1-k}) \quad u_{kt_1} = u_{kx}, \quad k = 2, 3, \ldots \quad \Rightarrow \quad t_1 \equiv x, \tag{17}$$

for $m = 2$

$$\begin{aligned}
&\partial_x^{-1}) \quad u_{2t_2} = u_{2xx} + 2u_{3x}, \\
&\partial_x^{-2}) \quad u_{3t_2} = u_{3xx} + 2u_{4x} + 2u_2 \star u_{2x} + 2[u_2, u_3]_\star, \\
&\partial_x^{-3}) \quad u_{4t_2} = u_{4xx} + 2u_{5x} + 4u_3 \star u_{2x} - 2u_2 \star u_{2xx} + 2[u_2, u_4]_\star, \quad \ldots
\end{aligned} \tag{18}$$

and for $m = 3$

$$\begin{aligned}
&\partial_x^{-1}) \quad u_{2t_3} = u_{2xxx} + 3u_{3xx} + 3u_{4x} + 3u_{2x} \star u_2 + 3u_2 \star u_{2x}, \\
&\partial_x^{-2}) \quad u_{3t_3} = 3u_{4xx} + 6u_2 \star u_{3x} + 3u_{2x} \star u_3 + 3u_3 \star u_{2x} + 3[u_2, u_4]_\star, \quad \ldots.
\end{aligned} \tag{19}$$

These just imply the NC KP equation (8) with $2u_2 \equiv u$, $t_2 \equiv y$, $t_3 \equiv t$. Important point is that infinite kind of fields $u_3, u_4, u_5, \ldots$ are represented in terms of one kind of field $2u_2 \equiv u$ as is seen in equation (18). This guarantees the existence of NC KP hierarchy and the infinite differential equations are called the *NC (KP) hierarchy equations*.

Putting the constraint $L^l = B_l$ on the NC KP hierarchy (14), we get infinite set of NC hierarchies. Then the following NC hierarchy:

$$\left[\partial_{t_m} - B_m, L^l\right]_\star = 0, \tag{20}$$

becomes a NC differential equation. We can easily show

$$\frac{\partial u}{\partial t_{Nl}} = 0, \qquad N = 1, 2, \dots \tag{21}$$

because of $B_{Nl} = L^{Nl}$. The reduced NC hierarchy is called the *l-reduction* of NC KP hierarchy.

NC KdV hierarchy (2-reduction of NC KP). Taking the constraint $L^2 = B_2$, we get the KdV hierarchy. The Lax equation:

$$\frac{\partial u}{\partial t_m} = \left[B_m, L^2\right]_\star, \tag{22}$$

gives rise to the m-th KdV hierarchy equation which becomes, for example, the (third) NC KdV equation (7) with $t_3 \equiv t$ and the 5-th NC KdV equation [17]:

$$u_{t_5} = \frac{1}{16}u_{xxxxx} + \frac{5}{16}(u \star u_{xxx} + u_{xxx} \star u) + \frac{5}{8}(u_x \star u_x + u \star u \star u)_x. \tag{23}$$

In Lax-pair generating technique, the B_m-operator is given by the ansatz $B_m = \partial_x^{m-2} L_{\mathrm{KdV}} + B'$.

NC Boussinesq hierarchy (3-reduction of NC KP). The 3-reduction $L^3 = B_3$ yields the NC Boussinesq hierarchy. The Lax equation:

$$\frac{\partial u}{\partial t_m} = \left[B_m, L^3\right]_\star, \tag{24}$$

leads to the m-th Boussinesq hierarchy equation which is, for $m = 3$, the NC Boussinesq equation [17]:

$$u_{tt} = \frac{1}{3}u_{xxxx} + (u \star u)_{xx} + ([u, \partial_x^{-1} u_t]_\star)_x. \tag{25}$$

In this way, we can generate infinite set of the l-reduced NC hierarchies. Furthermore, if we take other set-up for the definition of pseudo-differential operator L and "time-evolution" operator B_m, we can get many other hierarchies as follows.

NC modified KdV (mKdV) hierarchy. If we take

$$L = \partial_x + u_1 + u_2\partial_x^{-1} + u_3\partial_x^{-2} + \cdots, \qquad B_m = (L^m)_{\star \geq 1}, \tag{26}$$

and put the constraint $L^2 = B_2$, infinite kind of fields $u_2, u_3, \dots$ are represented in terms of one kind of field $2u_1 \equiv v$. We can easily see $\partial_{t_{2N}} v = 0$. The set of Lax equations:

$$\left[B_m - \partial_{t_m}, L^2\right]_\star = 0 \tag{27}$$

yields NC mKdV hierarchy which implies the NC mKdV equation for $m = 3$ with $t_3 \equiv t$:

$$\frac{\partial v}{\partial t} = \frac{1}{4}v_{xxx} - \frac{3}{8}v \star v_x \star v + \frac{3}{8}[v, v_{xx}]_\star. \tag{28}$$

We note that the NC mKdV equation (28) is different from that in [3] from NC KdV equation (7) via NC Miura map $u = -v \star v - v_x$. The NC mKdV hierarchy can be considered as the 2-reduction of NC mKP hierarchy. However the existence of the NC mKP hierarchy seems to be nontrivial because it cannot be represented in terms of one kind of field. (The NC mKP equation given in early versions of [21] is incorrect.) For the same reason, the higher reduction of the NC mKP hierarchy seems to be hard to obtain.

NC Burgers hierarchy [24]. If we take

$$L = \partial_x + u_1 + u_2\partial_x^{-1} + u_3\partial_x^{-2} + \cdots, \qquad B_m = (L^m)_{\star \geq 1}, \tag{29}$$

and put the constraint $L = B_1 =: \partial_x + v$, the hierarchy:

$$\partial_{t_m} v = [B_m, L]_\star \tag{30}$$

yields the NC Burgers hierarchy which implies the NC Burgers equation:

$$\frac{\partial v}{\partial t_2} = [B_2, L]_\star = \left[\partial_x^2 + 2v\partial_x, \partial_x + v\right]_\star = v_{xx} + 2v \star v_x. \tag{31}$$

and the third-order NC Burgers equation:

$$\frac{\partial v}{\partial t_3} = [B_3, L]_\star = v_{xxx} + 3v \star v_{xx} + 3v_x \star v_x + 3v \star v \star v_x \tag{32}$$

and so on. The nonlinear terms are not symmetric, which will be proved to be a key point in the linearization in the next section. The B_m-operator is given in Lax-pair generating technique by $B_m = \partial_x^{m-1} L + B'$. This time, the generated equations contain some parameters and thus covers wider class of Lax equations [24].

5 Integrability of noncommutative Burgers equation

In this section, we discuss the integrability of the Burgers equation (31) on NC (1+1)-dimensional space-time where the coordinate and the noncommutativity are denoted by $(x, t) \equiv (t_1, t_2)$ and $[t, x] = i\theta$, respectively.

In commutative case, it is well known that the Burgers equation is linearized by the Cole–Hopf transformation. The discussion can be extended to noncommutative case [24, 25]. NC Burgers equation (31) can be linearized by the following noncommutative analogue of the Cole–Hopf transformation: $v = \psi^{-1} \star \psi_x$. The linearized equation is a (NC) diffusion equation: $\psi_t = \psi_{xx}$. The naive solution of the above NC diffusion equation is

$$\psi(t, x) = 1 + \sum_{i=1}^{N} h_i e^{k_i^2 t} \star e^{\pm k_i x} = 1 + \sum_{i=1}^{N} h_i e^{\frac{i}{2} k_i^3 \theta} e^{k_i^2 t \pm k_i x}, \tag{33}$$

where h_i, k_i are complex constants. In the commutative limit, this reduces to the N-shock wave solution in fluid dynamics. The final form in (33) shows that the N-shock wave solution is deformed by $e^{\frac{i}{2} k_i^3 \theta}$ due to the noncommutativity. The explicit representation in terms of v is hard to obtain because the derivation of ψ^{-1} in the NC Cole–Hopf transformation is nontrivial. However we can discuss the asymptotic behaviors at $t \to \pm\infty$ and actually see the effect of the NC deformation. In fact, the exact solutions for $N = 1, 2$ are obtained in [25] and nontrivial effects of the NC-deformation are reported. We note that NC one shock-wave solutions can always reduce to the commutative ones because $f(t - x) \star g(t - x) = f(t - x)g(t - x)$ [24].

The results show that the NC Burgers equation (31) is completely integrable even though the NC Burgers equation contains infinite number of time-derivatives in the nonlinear term. The linearized equation is a differential equation of first order with respect to time and the initial value problem is well-defined. This is a surprising result. The (NC) diffusion equation can be solved for arbitrarily boundary conditions by the Fourier transformation. Furthermore, we note that the form of the nonlinear term in the NC Burgers equation (31) is crucial for the linearization. If it becomes symmetric like the NC KdV equation (7), the linearization is proved to be impossible [24].

6 Conclusion and discussion

In this article, we presented various NC Lax equations and proved the existence of many NC hierarchies. The NC extension of Sato theory is new. We also confirmed that NC Burgers equation is linearizable and completely integrable even though it is a differential equation of infinite order with respect to time. The linearized equation is a (NC) diffusion equation and can be solved in usual ways.

NC extension of Ward conjecture [33] would be very interesting [21] though we have omitted it in this article because of limitations of space. Some NC equations are actually derived from NC (anti-)self-dual YM equations by reduction [8, 24] and embedded [9, 12, 34] in $N = 2$ string theory [35]. This guarantees that NC integrable equations would have a physical meaning and might be helpful to understand new aspects of the corresponding string theory.

The next step is NC extension of Hirota's bilinearization [36]. This could be realized as a simple generalization of the Cole–Hope transformation whose extension to NC spaces are already successful as shown in Section 5. Hirota's bilinearization leads to the theory of tau-functions. Sato theory is based on the existence of hierarchies and tau-functions. We have just revealed the existence of hierarchies and the completion of NC Sato theory would be drawing near at hand.

We give an overview of recent developments of nonlocal constructions in the geometry of partial differential equations and their applications to Bäcklund transformations, Hamiltonian and symplectic structures, recursion operators, etc.

This is an overview of recent results obtained by the authors and related to using of nonlocal constructions in geometry of partial differential equations. For general references concerning geometry of PDE see [1, 15].

Let $\mathscr{E} \subset J^\infty(\pi) \xrightarrow{\pi_\infty} M$ be an infinitely prolonged differential equation considered as a submanifold in an appropriate manifold of infinite jets. Then $\mathscr{E}$ is endowed with a natural finite-dimensional integrable distribution[1] (the *Cartan distribution* denoted by $\mathscr{C}$) locally spanned by the total derivatives. Invariantly, at any point $\theta \in \mathscr{E}$ the space $\mathscr{C}_\theta$ is the span of all tangent planes to the graphs of jets passing through θ. A fiber bundle $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ is called a *covering* over $\mathscr{E}$ if (a) $\tilde{\mathscr{E}}$ is endowed with an integrable distribution $\tilde{\mathscr{C}}$, $\dim \tilde{\mathscr{C}} = \dim \mathscr{C}$ and (b) $\tau_* \tilde{\mathscr{C}}_y = \mathscr{C}_{\tau(y)}$ for any $y \in \tilde{\mathscr{E}}$. A $\pi_\infty \circ \tau$-vertical vector field X is called a *nonlocal symmetry* of $\mathscr{E}$ if it preserves $\tilde{\mathscr{C}}$. Note that since the distributions $\mathscr{C}$ and $\tilde{\mathscr{C}}$ are *horizontal*, they determine flat connections in the bundles π_∞ and $\pi_\infty \circ \tau$ respectively. We call these connections the *Cartan connections* and use the same notation, $\mathscr{C}$ and $\tilde{\mathscr{C}}$, for them.

A $\tau \circ \pi_\infty$-vertical vector field X on $\tilde{\mathscr{E}}$ is called a *nonlocal τ-symmetry* if $[X, \tilde{\mathscr{C}}] \subset \tilde{\mathscr{C}}$. They form a Lie algebra denoted by $\operatorname{sym}_\tau \mathscr{E}$. Nonlocal symmetries can be expressed in finite terms rather rarely. A good (and rather useful) substitute is the notion of a *shadow* (that is often mixed up with nonlocal symmetries themselves!). Naively, in local coordinates a shadow can be introduced as follows. Note that any vector field X lying in the Cartan distribution can be uniquely lifted to a field $\tilde{X}$ lying in $\tilde{\mathscr{C}}$ such that $\tau_* \tilde{X} = X$. Moreover, one has $\widetilde{[X, Y]} = [\tilde{X}, \tilde{Y}]$. Consequently, any linear differential operator Δ on $\mathscr{E}$ expressed in total derivatives (a so-called *$\mathscr{C}$-differential operator*) is lifted to an operator $\tilde{\Delta}$ on $\tilde{\mathscr{E}}$. In particular, assume that $\mathscr{E}$ is given by a differential operator F and $\ell_{\mathscr{E}}$ is the restriction of its linearization to $\mathscr{E}$. Then $\ell_{\mathscr{E}}$ can be lifted to an operator $\tilde{\ell}_{\mathscr{E}}$ on $\tilde{\mathscr{E}}$. Consider a solution φ of the equation $\tilde{\ell}_{\mathscr{E}}(\varphi) = 0$. Then to such a φ there corresponds a derivation $S_\varphi\colon C^\infty(\mathscr{E}) \to C^\infty(\tilde{\mathscr{E}})$. This derivation (or φ itself) is called a shadow in the covering τ, or a *τ-shadow*. The *Reconstruction Theorem* (see [10, 14] and below) states that for any shadow S_φ in τ there exist a covering $\mathscr{E}_\varphi \xrightarrow{\tau_\varphi} \tilde{\mathscr{E}} \xrightarrow{\tau} \mathscr{E}$ and a nonlocal symmetry S in this covering such that $S|_{C^\infty(\mathscr{E})} = S_\varphi$. Vice versa, any derivation $S\colon C^\infty(\mathscr{E}) \to C^\infty(\tilde{\mathscr{E}})$ that takes the Cartan distribution on $\mathscr{E}$ to that on $\tilde{\mathscr{E}}$ is locally identified with a τ-shadow. Thus, this property of S can be taken for the global definition of shadows.

In a similar way, one can consider the adjoint operator $\ell^*_{\mathscr{E}}$ and its lifting $\tilde{\ell}^*_{\mathscr{E}}$ to $\tilde{\mathscr{E}}$. In what follows, we assume that the equation under consideration satisfies the conditions of *Vinogradov's Two-Line Theorem* [18–20]. Then solutions of the equation $\tilde{\ell}^*_{\mathscr{E}}(\psi) = 0$ are called *nonlocal gen-*

[1] Integrability in this case means that for any two vector fields $X, Y \in \mathscr{C}$ their commutator $[X, Y]$ lies in $\mathscr{C}$ as well.

erating functions. Nonlocal symmetries (and their shadows) and generating functions naturally arise in various problems related to geometry of PDE. We shall consider some of them below.

1 The long exact sequence of a covering

Let $\mathscr{E} \subset J^\infty(\pi)$, as before, be an infinitely prolonged differential equation understood as a submanifold in the manifold of infinite jets, $\pi_\infty\colon \mathscr{E} \to M$ be the natural projection. Consider a covering $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ and the *structure element*[2] $U_\tau \in \mathrm{D}^{\mathrm{v}}(\Lambda^1(\tilde{\mathscr{E}})) \subset \mathrm{D}(\Lambda^1(\tilde{\mathscr{E}}))$, where (and below) $\mathrm{D}(\Lambda^i(\tilde{\mathscr{E}}))$ denotes the module of $\Lambda^i(\tilde{\mathscr{E}})$-valued derivations $C^\infty(\tilde{\mathscr{E}}) \to \Lambda^i(\tilde{\mathscr{E}})$ while $\mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}}))$ consists of π_∞-vertical derivation. Then (see [12]) the *$\mathscr{C}$-complex*

$$0 \to \mathrm{D}^{\mathrm{v}}(\tilde{\mathscr{E}}) \xrightarrow{\partial_\tau} \mathrm{D}^{\mathrm{v}}(\Lambda^1(\tilde{\mathscr{E}})) \to \cdots \to \mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}})) \xrightarrow{\partial_\tau} \mathrm{D}^{\mathrm{v}}(\Lambda^{i+1}(\tilde{\mathscr{E}})) \to \cdots \tag{1}$$

arises, where the differential $\partial_\tau = [\![U_\tau, \cdot]\!]^{\mathrm{n}}$ is defined by the *Frölicher–Nijenhuis bracket*. The corresponding cohomology is denoted by $H^i_{\mathscr{C}}(\tilde{\mathscr{E}})$ and called the *$\mathscr{C}$-cohomology* of the covering τ.

Consider the module $\mathrm{D}^{\mathrm{g}}(\Lambda^i(\tilde{\mathscr{E}})) = \{X \in \mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}}) \mid X(C^\infty(\mathscr{E})) = 0\}$, where $C^\infty(\mathscr{E})$ is understood as a subalgebra in $C^\infty(\tilde{\mathscr{E}})$. Let also $\mathrm{D}^{\mathrm{s}}(\Lambda^i(\tilde{\mathscr{E}})) = \mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}}))/\mathrm{D}^{\mathrm{g}}(\Lambda^i(\tilde{\mathscr{E}}))$ be the quotient module. By basic properties of the Frölicher–Nijenhuis bracket, $\partial_\tau(\mathrm{D}^{\mathrm{g}}(\Lambda^i(\tilde{\mathscr{E}}))) \subset \mathrm{D}^{\mathrm{g}}(\Lambda^{i+1}(\tilde{\mathscr{E}}))$ and thus the short exact sequence of complexes

$$\begin{array}{ccccccccc}
 & & \vdots & & \vdots & & \vdots & & \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathrm{D}^{\mathrm{g}}(\Lambda^i(\tilde{\mathscr{E}})) & \longrightarrow & \mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}})) & \longrightarrow & \mathrm{D}^{\mathrm{s}}(\Lambda^i(\tilde{\mathscr{E}})) & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle \partial_\tau} & & \downarrow{\scriptstyle \partial_\tau} & & \downarrow{\scriptstyle \partial_\tau} & & \\
0 & \longrightarrow & \mathrm{D}^{\mathrm{g}}(\Lambda^{i+1}(\tilde{\mathscr{E}})) & \longrightarrow & \mathrm{D}^{\mathrm{v}}(\Lambda^{i+1}(\tilde{\mathscr{E}})) & \longrightarrow & \mathrm{D}^{\mathrm{s}}(\Lambda^{i+1}(\tilde{\mathscr{E}})) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
 & & \vdots & & \vdots & & \vdots & &
\end{array} \tag{2}$$

arises (we preserve the notation ∂_τ for the differential in both quotient and subcomplexes). Denote by $H^i_{\mathrm{s}}(\tilde{\mathscr{E}})$ and $H^i_{\mathrm{g}}(\tilde{\mathscr{E}})$ the cohomology groups of the quotient and subcomplexes, respectively.

Definition 1. The groups $H^i_{\mathrm{s}}(\tilde{\mathscr{E}})$ and $H^i_{\mathrm{g}}(\tilde{\mathscr{E}})$ are called *shadow* and *gauge* $\mathscr{C}$-cohomologies of the covering τ, respectively. The cohomological sequence

$$\begin{aligned}
&0 \to H^0_{\mathrm{g}}(\tilde{\mathscr{E}}) \xrightarrow{\alpha} H^0_{\mathscr{C}}(\tilde{\mathscr{E}}) \xrightarrow{\beta} H^0_{\mathrm{s}}(\tilde{\mathscr{E}}) \xrightarrow{\partial} H^1_{\mathrm{g}}(\tilde{\mathscr{E}}) \to \cdots \\
&\quad \to H^i_{\mathrm{g}}(\tilde{\mathscr{E}}) \xrightarrow{\alpha} H^i_{\mathscr{C}}(\tilde{\mathscr{E}}) \xrightarrow{\beta} H^i_{\mathrm{s}}(\tilde{\mathscr{E}}) \xrightarrow{\partial} H^{i+1}_{\mathrm{g}}(\tilde{\mathscr{E}}) \to \cdots
\end{aligned} \tag{3}$$

corresponding to (2) is called the *long exact sequence* of the covering τ.

Remark 1. Recall (see [12]) that the modules $\Lambda^i(\tilde{\mathscr{E}})$ split into the direct sum

$$\Lambda^i(\tilde{\mathscr{E}}) = \oplus_{p+q=i}\Lambda^{p,q}(\tilde{\mathscr{E}}), \qquad \Lambda^{p,q}(\tilde{\mathscr{E}}) = \mathscr{C}\Lambda^p(\tilde{\mathscr{E}}) \otimes \Lambda^q_h(\tilde{\mathscr{E}}), \tag{4}$$

where $\mathscr{C}\Lambda^p(\tilde{\mathscr{E}})$ and $\Lambda^q_h(\tilde{\mathscr{E}})$ are modules of *Cartan* and *horizontal* forms, respectively. To (4) there corresponds the splitting $\mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}})) = \oplus_{p+q=i}\mathrm{D}^{\mathrm{v}}(\Lambda^{p,q}(\tilde{\mathscr{E}}))$ and the differential ∂_τ takes

[2]The structure element U_τ may be understood as the *connection form* of the Cartan connection $\tilde{\mathscr{E}}$. In a similar way, we call the connection form of $\mathscr{C}$ the structure element of $\mathscr{E}$.

elements $\mathrm{D}^{\mathrm{v}}(\Lambda^{p,q}(\tilde{\mathscr{E}}))$ to $\mathrm{D}^{\mathrm{v}}(\Lambda^{p,q+1}(\tilde{\mathscr{E}}))$. This leads to the cohomology groups $H^{p,q}_{\mathscr{C}}(\tilde{\mathscr{E}})$, $H^{p,q}_{\mathrm{s}}(\tilde{\mathscr{E}})$ and $H^{p,q}_{\mathrm{s}}(\tilde{\mathscr{E}})$ and (3) actually splits into the series of the following sequences

$$0 \to H^{p,0}_{\mathrm{g}}(\tilde{\mathscr{E}}) \xrightarrow{\alpha} H^{p,0}_{\mathscr{C}}(\tilde{\mathscr{E}}) \xrightarrow{\beta} H^{p,0}_{\mathrm{s}}(\tilde{\mathscr{E}}) \xrightarrow{\partial} H^{p,1}_{\mathrm{g}}(\tilde{\mathscr{E}}) \to \cdots$$
$$\cdots \to H^{p,q}_{\mathrm{g}}(\tilde{\mathscr{E}}) \xrightarrow{\alpha} H^{p,q}_{\mathscr{C}}(\tilde{\mathscr{E}}) \xrightarrow{\beta} H^{p,q}_{\mathrm{s}}(\tilde{\mathscr{E}}) \xrightarrow{\partial} H^{p,q+1}_{\mathrm{g}}(\tilde{\mathscr{E}}) \to \cdots$$

The groups $H^{p,q}_{\mathscr{C}}(\tilde{\mathscr{E}})$ are identified with the *horizontal cohomology* of $\tilde{\mathscr{E}}$ with coefficients in $\mathrm{D}^{\mathrm{v}}(\mathscr{C}\Lambda^p(\tilde{\mathscr{E}}))$ [17].

1.1 Interpretations

Before discussing particular applications of the above constructions, let us describe the geometrical meaning of some of the groups in (3) that we shall need below.

$H^0_{\mathscr{C}}(\tilde{\mathscr{E}})$**:** elements of this group are identified with *nonlocal τ-symmetries*;

$H^0_{\mathrm{g}}(\tilde{\mathscr{E}})$**:** these are *gauge symmetries* in τ, i.e., τ-vertical symmetries (the corresponding diffeomorphisms, if they exist, are automorphisms of τ);

$H^0_{\mathrm{s}}(\tilde{\mathscr{E}})$**:** this cohomology group consists of *τ-shadows* of nonlocal symmetries, i.e., π_∞-vertical derivations $X\colon C^\infty(\mathscr{E}) \to C^\infty(\tilde{\mathscr{E}})$ preserving the Cartan distributions. As it was already mentioned, in local coordinates, shadows are described by vector-functions $\varphi = (\varphi^1, \dots, \varphi^m)$, $\varphi^l \in C^\infty(\tilde{\mathscr{E}})$, $m = \dim \pi$, satisfying the equation $\tilde{\ell}_{\mathscr{E}}(\varphi) = 0$, where $\tilde{\ell}_{\mathscr{E}}$ is the linearization of $\mathscr{E}$ naturally lifted to $\tilde{\mathscr{E}}$;

$H^1_{\mathscr{C}}(\tilde{\mathscr{E}})$**:** these are equivalence classes of nontrivial *infinitesimal deformations* of U_τ, i.e., of the element defining the basic geometrical structure on $\tilde{\mathscr{E}}$; a deformation is infinitesimally trivial if and only if its cohomological class in $H^1_{\mathscr{C}}(\tilde{\mathscr{E}})$ vanishes. On the other hand, elements of $H^1_{\mathscr{C}}(\tilde{\mathscr{E}})$ act on $H^0_{\mathscr{C}}(\tilde{\mathscr{E}}) = \mathrm{sym}_\tau \mathscr{E}$ by contraction: $R(X) = \mathrm{i}_X(R)$, $X \in H^0_{\mathscr{C}}(\tilde{\mathscr{E}})$, $R \in H^1_{\mathscr{C}}(\tilde{\mathscr{E}})$. Nontrivial actions may correspond to elements of $H^{1,0}_{\mathscr{C}}(\tilde{\mathscr{E}})$ only;

$H^1_{\mathrm{g}}(\tilde{\mathscr{E}})$**:** those cohomological classes are *τ-vertical*, or *gauge*, deformations. They deform the covering structure itself only and do not change the structure of the underlying equation $\mathscr{E}$;

$H^1_{\mathrm{s}}(\tilde{\mathscr{E}})$**:** Similar to $H^0_{\mathrm{s}}(\tilde{\mathscr{E}})$, these are also shadows of $H^1_{\mathscr{C}}(\tilde{\mathscr{E}})$, i.e., classes of π_∞-vertical derivations $C^\infty(\mathscr{E}) \to \Lambda^1(\tilde{\mathscr{E}})$ that preserve the Cartan distributions. Elements of $H^{1,0}_{\mathrm{s}}(\tilde{\mathscr{E}})$ have the following local description: $\mu = (\mu^1, \dots, \mu^m)$, $\mu^l \in \mathscr{C}\Lambda^1(\tilde{\mathscr{E}})$ lies in $H^{1,0}_{\mathrm{s}}(\tilde{\mathscr{E}})$ if and only if $\tilde{\ell}_{\mathscr{E}}(\mu) = 0$.

1.2 Reconstruction of shadows

Consider again a covering $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ and a shadow $\varphi\colon C^\infty(\mathscr{E}) \to C^\infty(\tilde{\mathscr{E}})$. We say that φ is *reconstructible* in τ if there exists a symmetry $X\colon C^\infty(\tilde{\mathscr{E}}) \to C^\infty(\tilde{\mathscr{E}})$ such that $X\big|_{C^\infty(\mathscr{E})} = \varphi$. Of course, given a covering τ, not any shadow can be reconstructed in this covering, but a weaker result was found by N. Khor'kova and proved in [14]:

Theorem 1 (Reconstruction Theorem). *Let $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ be a covering and φ be a τ-shadow. Then there exists a covering $\tau_\varphi\colon \mathscr{E}_\varphi \to \tilde{\mathscr{E}}$ such that φ is reconstructible in the composition covering $\tau \circ \tau_\varphi\colon \mathscr{E}_\varphi \to \mathscr{E}$.*

Remark 2. How the theorem works in practice may be seen in the classical example of the KdV equation

$$u_t = uu_x + u_{xxx}. \tag{5}$$

It is known that this equation possesses two infinite series of symmetries – a local one, independent of x and t and consisting of higher KdV equations, and another, (x,t)-dependent series whose first two terms are local (the Galilean boost and a scaling symmetry) and all others are nonlocal. Take the first nonlocal one. It has the form $\psi_5 = tu_{xxxxx} + \cdots$ and contains the nonlocal variable w^1 defined by the relations

$$w^1_x = u, \qquad w^1_t = \tfrac{1}{2}u^2 + u_{xx}. \tag{6}$$

Actually, ψ_5 is not a symmetry but only a shadow in the covering corresponding to (6). To reconstruct the symmetry, one needs to find the coefficient at $\partial/\partial w^1$. But when we do this, a new nonlocal variable w^2 arises that is to satisfy the relation $w^2_x = u^2$, etc. As it was shown in [10], this process 'stops' at infinity only: to reconstruct the initial shadow, one has to add all nonlocal variables of the form $w^j_x = c^j$, where c^j is the density of the jth conservation law. As we shall see, this situation is somewhat typical.

Proof of Theorem 1. Consider the following part of (3) $H^0_{\mathscr{C}}(\tilde{\mathscr{E}}) \xrightarrow{\beta} H^0_{\mathrm{s}}(\tilde{\mathscr{E}}) \xrightarrow{\partial} H^1_{\mathrm{g}}(\tilde{\mathscr{E}})$. Let $\varphi \in H^0_{\mathrm{s}}(\tilde{\mathscr{E}})$ be a shadow in the covering τ. It is reconstructible if there exists a symmetry $X \in H^0_{\mathscr{C}}(\tilde{\mathscr{E}})$ such that $\beta(X) = \varphi$. Due to the exactness, this is equivalent to $\partial(\varphi) = 0$. Thus the element $\omega_\varphi = \partial(\varphi)$ is the obstruction to reconstructibility of the shadow φ. So, the intermediate result is

Proposition 1. *A shadow $\varphi \in H^0_{\mathrm{s}}(\tilde{\mathscr{E}})$ is reconstructible in the covering τ if and only if the obstruction $\omega_\varphi \in H^{0,1}_{\mathrm{g}}(\tilde{\mathscr{E}})$ vanishes.*

The obstruction ω_φ is represented by a vector-valued horizontal 1-form on $\tilde{\mathscr{E}}$, the number of its components ω^l_φ equals the dimension of the covering τ. Each form ω^l_φ is closed and thus determines a 1-dimensional covering τ^l over $\tilde{\mathscr{E}}$, see [14]. This covering is trivial if and only if this form is exact (with respect to the horizontal de Rham differential) and $\omega_\varphi = 0$ if and only if all ω^l_φ are exact. Thus, if we choose those ω^l_φ whose horizontal cohomology classes are nontrivial, take the corresponding 1-dimensional coverings and consider the Whitney product $\tilde{\tau}\colon \tilde{\tilde{\mathscr{E}}} \to \tilde{\mathscr{E}}$ then the obstruction ω_φ will vanish in this covering, but a new obstruction of the same nature may arise. If the latter vanishes the shadow is reconstructible in $\tilde{\tau} = \tau_\varphi$, otherwise we must repeat the construction, etc. Eventually, we shall either stop at some finite step, or shall arrive to an infinite covering τ_φ. In both cases, there will be no obstruction to reconstruct the shadow φ. ■

Remark 3. From the proof of the theorem it can be seen that the shadow φ completely determines the 'minimal' covering, where it reconstructs to a symmetry. In the case of a two-dimensional base M (i.e., when the equation $\mathscr{E}$ is in two independent variables) the cohomology classes of the forms ω^l_φ are identified with *conservation laws* of $\mathscr{E}$, generally nonlocal. But in some cases (for the KdV and similar equations) the reconstruction procedure deals with local conservation laws only, see [10].

Remark 4. Though the covering, where the shadow at hand reconstructs, is well defined (but not uniquely!) algorithmically, the symmetry that corresponds to this shadow is definitely not unique: even when a covering τ_φ is chosen, a symmetry corresponding to φ is defined up to elements of $H^0_{\mathrm{g}}(\mathscr{E}_\varphi)$, i.e., up to gauge symmetries in τ_φ. This means that to deal with nonlocal symmetries is not the same as to deal with their shadows.

1.3 Toward Bäcklund transformations [3]

Geometrically, a *Bäcklund transformation* between two differential equations $\mathscr{E}$ and $\mathscr{E}'$ is a pair of coverings $\mathscr{E} \xleftarrow{\tau} \tilde{\mathscr{E}} \xrightarrow{\tau'} \mathscr{E}'$. This geometrical construction may be understood as a differential

relation between solutions of $\mathscr{E}$ and $\mathscr{E}'$. If $s \subset \mathscr{E}$ is a solution of $\mathscr{E}$ then $\tau^{-1}(s)$ is fibered by a $\dim\tau$-dimensional family of solutions to $\tilde{\mathscr{E}}$ while $\tau'(\tau^{-1}(s))$ delivers solutions to $\mathscr{E}'$, and vice versa.

In applications, one of the most important cases is when $\mathscr{E} = \mathscr{E}'$ and τ, τ' belong to a smooth family of coverings τ_t, $t \in \mathbb{R}$ being a nonremovable[3] parameter. Such a family may be regarded as a *deformation* of the covering τ_{t_0}. These deformations may be treated as follows.

Essentially, we repeat here the main result given in [3]. Let us first recall the following construction, see [14]. Let $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ be a covering and X be a symmetry of $\mathscr{E}$ possessing a one-parameter group of transformations $A_t\colon \mathscr{E} \to \mathscr{E}$. Consider an arbitrary lift of A_t to $\tilde{\mathscr{E}}$ such that the diagram

$$\begin{array}{ccc} \tilde{\mathscr{E}} & \xrightarrow{\tilde{A}_t} & \tilde{\mathscr{E}} \\ {\scriptstyle\tau}\downarrow & & \downarrow{\scriptstyle\tau} \\ \mathscr{E} & \xrightarrow{A_t} & \mathscr{E} \end{array} \tag{7}$$

is commutative. Let us define on $\tilde{\mathscr{E}}$ a t-parameter family of distributions $\tilde{\mathscr{C}}_t$ by setting

$$(\tilde{\mathscr{C}}_t)_{\tilde{\theta}} = (\tilde{A}_t)_*^{-1}\tilde{\mathscr{C}}_{\tilde{A}_t\tilde{\theta}}, \qquad \tilde{\theta} \in \tilde{\mathscr{E}}.$$

All distributions $\tilde{\mathscr{C}}_t$ are integrable, i.e., $[\tilde{\mathscr{C}}_t, \tilde{\mathscr{C}}_t] \subset \tilde{\mathscr{C}}_t$, and thus $\tilde{\mathscr{E}}_t = (\tilde{\mathscr{E}}, \tilde{\mathscr{C}}_t)$ covers $\mathscr{E}$ by means of τ. Denote this covering by $\tau_t\colon \tilde{\mathscr{E}}_t \to \mathscr{E}$ and notice that if $\tilde{A}'_t$ is another lift satisfying (7) then for any t the covering τ_t is either equivalent to τ'_t or not. It for all t (sufficiently small) τ_t and τ'_t are equivalent then this means that X can be lifted to a symmetry of $\tilde{\mathscr{E}}$. Thus we obtain

Proposition 2. *Let $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ be a covering and X be a symmetry of $\mathscr{E}$ possessing a one-parameter group of transformations and such that it cannot be lifted to a symmetry of $\tilde{\mathscr{E}}$. Then X generates a one-parameter family of (equivalence classes of) coverings $\tau_t\colon \tilde{\mathscr{E}}_t \to \tilde{\mathscr{E}}$ such that*

1. *$\tilde{\mathscr{E}}_t$ and $\tilde{\mathscr{E}}_{t'}$ isomorphic as manifolds with distributions;*
2. *τ_t and $\tau_{t'}$ are pair-wise inequivalent for sufficiently small t and t'.*

We say that a family τ_t satisfying properties 1 and 2 above is *irreducible*.

Remark 5. Let $\mathfrak{g}$ be a finite-dimensional Lie subalgebra in the algebra of classical symmetries of $\mathscr{E}$. Then we obtain a G/H-irreducible family, where G is the Lie group corresponding to $\mathfrak{g}$ and H is the stabilizer of τ under the above described action.

Remark 6. Proposition 2 means that if we have a covering τ and a shadow that cannot be reconstructed to a symmetry in this covering[4] then, under certain conditions, this shadow generates an irreducible family of coverings. As we see below, this is, in a sense, a general way to obtain irreducible families.

Consider an irreducible family of coverings $\tau_t\colon \tilde{\mathscr{E}} \to \mathscr{E}$, $\tau_0 = \tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$, and the following part of (3)

$$H^0_{\mathscr{C}}(\tilde{\mathscr{E}}) \xrightarrow{\beta} H^0_{\mathrm{s}}(\tilde{\mathscr{E}}) \xrightarrow{\partial} H^{0,1}_{\mathrm{g}}(\tilde{\mathscr{E}}) \xrightarrow{\alpha} H^{0,1}_{\mathscr{C}}(\tilde{\mathscr{E}}).$$

The family τ_t may be considered as a deformation of τ; hence its infinitesimal part μ lies in $H^{0,1}_{\mathrm{g}}(\tilde{\mathscr{E}})$. By Property 1 from Proposition 2, the corresponding deformation of $\tilde{\mathscr{E}}$ is trivial and thus $\alpha(\mu) = 0$. By the exactness, $\mu = \partial(\varphi)$, $\varphi \in H^0_{\mathrm{s}}(\tilde{\mathscr{E}})$. The deformation τ_t is infinitesimally nontrivial if and only if $\mu \neq 0$ and, again by the exactness, if and only if $\varphi \neq \beta(X)$, $X \in H^0_{\mathscr{C}}(\tilde{\mathscr{E}})$, i.e., if and only if φ is not reconstructible to a τ-symmetry. To state the final result, it remains to note that the action of ∂ is given by $[\![U_\tau, \cdot]\!]^{\mathrm{n}}$.

[3] I.e., for any $t_1 \neq t_2$ the coverings τ_{t_1} and τ_{t_2} are inequivalent.

[4] For the problem of reconstruction see Subsection 1.2.

Theorem 2. *Any irreducible family of coverings τ_t, $\tau_0 = \tau$, is infinitesimally generated by a τ-shadow that cannot be reconstructed to a nonlocal τ-symmetry.*

Remark 7. Of course, not to any shadow φ there corresponds an irreducible family of coverings. Anyway, we can construct a *formal deformation* $\exp(t\varphi)U_\tau$ and use it in some applications.

1.4 Action of recursion operators

We now pass to the last topic of this section. Let us first briefly recall the cohomological theory of recursion operators as it was exposed in [13]. Consider an equation $\mathscr{E}$ and the $\mathscr{C}$-complex (1) associated to it. Then, as it was already mentioned, the group $H^0_{\mathscr{C}}(\mathscr{E})$ is identified with the Lie algebra $\operatorname{sym}(\mathscr{E})$ of higher symmetries of $\mathscr{E}$. The contraction (or inner product) operation determines an action of elements of $H^1_{\mathscr{C}}(\mathscr{E})$ on $\operatorname{sym}(\mathscr{E})$ and nontrivial actions may correspond to the elements of $H^{1,0}_{\mathscr{C}}(\mathscr{E})$ only[5]. Locally, these elements are represented as Cartan vector-forms of degree 1, $\omega = (\omega_1, \dots, \omega_m)$, $\omega_l \in \mathscr{C}\Lambda^1(\mathscr{E})$, $m = \dim \pi$, satisfying the equation

$$\ell_{\mathscr{E}}(\omega) = 0. \tag{8}$$

Solving (8) and applying these solutions to the known symmetries we, in principle, can generate new symmetries. The same remains valid for nonlocal symmetries if we take $\tilde{\mathscr{E}}$ instead of $\mathscr{E}$. It is natural to anticipate that in this way we find recursion operators for symmetries of the equation at hand.

But in practice the picture is more complicated. If, for example, we realize the above procedure for the KdV equation (5) we shall obtain trivial solutions only. On the other hand, this equation possesses the recursion operator

$$R = D_x^2 + \frac{2}{3}u + \frac{1}{3}D_x^{-1},$$

where D_x is *total derivative* with respect to x. Of course, this operator could not be found by the described above method because of the nonlocal term D_x^{-1}. Such a term may arise in the covering given by (6), but if we try the same in this nonlocal setting the result will be negative again.

What actually gives nontrivial results is the following (see all the examples in [13]). Let us show how it works for the KdV equation. Namely, we do the following:

1. We take the covering $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ given by (6). Note that $\tilde{\mathscr{E}}$ is isomorphic to the infinite prolongation of the equation

   $$w_t = w_{xxx} + \tfrac{1}{2}u_x^2.$$

2. Then we consider the module of Cartan 1-forms on $\tilde{\mathscr{E}}$. It is generated by the forms

   $$\omega_k = du_k - u_{k+1}\,dx - D_x^k(u_3 + u_1)\,dt, \qquad \omega_{-1} = dw^1 - u\,dx - \left(u_2 + \tfrac{1}{2}u^2\right)\,dt,$$

   where $k = 0, 1, \dots$ and $u_k = u\underbrace{x\dots x}_{k \text{ times}}$, $u_0 = u$.

3. The next step is to solve the equation

   $$\tilde{\ell}_{\mathscr{E}}(\Omega) = 0, \tag{9}$$

   where $\tilde{\ell}_{\mathscr{E}}$ is the lift of the linearization to τ and $\Omega = \sum\limits_{k\geq -1} f_k\omega_k$.

[5]Note also that the contraction determines a structure of an associative algebra with unit on $H^1_{\mathscr{C}}(\mathscr{E})$.

4. Solving (9), we obtain two independent solutions: $\Omega_1 = \omega_0$ and $\Omega_2 = \omega_2 + \frac{2}{3}u\omega_0 + \frac{1}{3}\omega_{-1}$. The first one corresponds to the identical action while the second one gives the classical recursion operator for the KdV equation (see above).

So, from this scheme we see that construction of recursion operators amounts to computation of the group $H_1^{1,0}(\tilde{\mathscr{E}})$. Indeed, we have the following

Theorem 3. *Let $\mathscr{E}$ be an equation and $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ be a covering. Then the contraction operation generates the action $R\colon H^0_{\mathscr{C}}(\tilde{\mathscr{E}}) \to H^0_{\mathrm{s}}(\tilde{\mathscr{E}})$, where $R \in H^1_{\mathrm{s}}(\tilde{\mathscr{E}})$, i.e., elements of $H^1_{\mathrm{s}}(\tilde{\mathscr{E}})$ take τ-symmetries to τ-shadows*[6].

Remark 8. The result of this action, in general, is really a shadow. For example, applying the recursion operator of the KdV equation to the scaling symmetry $\psi_3 = tu_{xxx} + \cdots$, we obtain the element ψ_5 (see above) that reconstructs to a symmetry in the infinite-dimensional covering, where all conservation laws of the equation are 'killed'.

Proof of Theorem 3. The proof is very simple: consider the standard contraction

$$\mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}})) \lrcorner\, \mathrm{D}^{\mathrm{v}}(\Lambda^j(\tilde{\mathscr{E}})) \to \mathrm{D}^{\mathrm{v}}(\Lambda^{i+j-1}(\tilde{\mathscr{E}})).$$

It remains to note that if $X \in \mathrm{D}^{\mathrm{v}}(\Lambda^i(\tilde{\mathscr{E}}))$ and $Y \in \mathrm{D}^{\mathrm{s}}(\Lambda^j(\tilde{\mathscr{E}}))$ then $X \lrcorner\, Y \in \mathrm{D}^{\mathrm{s}}(\Lambda^{i+j-1}(\tilde{\mathscr{E}}))$ and that the differential in (1) preserves the inner product and thus the latter is inherited in the cohomology groups. ■

Remark 9. In some cases action of recursion operator on local symmetries leads to local symmetries again. For example, this is the case for classical hierarchies of integrable equations. Some remarks on how to establish locality may be found in [11].

2 Δ-coverings [7]

A covering $\tau\colon \tilde{\mathscr{E}} \to \mathscr{E}$ is said to be *linear* if τ is a vector bundle and for any vector field X on M the field $\tilde{X}$ lifted to $\tilde{\mathscr{E}}$ by the Cartan connection $\tilde{\mathscr{C}}$ preserves the subspace of fiber-wise linear functions in $C^\infty(\tilde{\mathscr{E}})$. If Δ is a $\mathscr{C}$-differential operator over $\mathscr{E}$, then there exists a canonical way to construct a linear covering associated to Δ. This covering is called Δ-*covering*. From *technical* point of view, Δ-coverings are useful to solve the following *factorization problem*: take another $\mathscr{C}$-differential operator ∇ and find $\mathscr{C}$-differential operators V and V' such that the equation

$$\nabla \circ V = V' \circ \Delta \tag{10}$$

holds.

Theorem 4. *Solutions $V \mod (\square \circ \Delta)$ of (10), where $\square$ is a $\mathscr{C}$-differential operator, are in one-to-one correspondence with fiber-wise linear solutions s of the equation $\tilde{\nabla}(s) = 0$, where $\tilde{\nabla}$ is the lifting of ∇ to the Δ-covering.*

There are two canonical coverings associated to a given equation. Namely, taking the operator $\ell_{\mathscr{E}}$, we obtain the $\ell_{\mathscr{E}}$-*covering* and for $\ell^*_{\mathscr{E}}$ one gets the $\ell^*_{\mathscr{E}}$-*covering*. The first one plays the role of the tangent bundle to $\mathscr{E}$ while the second is the counterpart of the cotangent bundle in the category of differential equations. This determines *conceptual* importance of the introduced constructions.

[6] Actually, nontrivial actions may correspond to the elements of $H^{1,0}_{\mathrm{s}}(\tilde{\mathscr{E}}) \subset H^1_{\mathrm{s}}(\tilde{\mathscr{E}})$ only.

In the simplest case of a scalar evolution equation $u_t = f(x, t, u, \dots, u_k)$ the ℓ-covering is described by additional coordinates $\omega = \omega_0, \omega_1, \dots$ that satisfy the relations

$$(\omega_i)_x = \omega_{i+1}, \qquad \omega_t = \sum_{i=0}^{k} \frac{\partial f}{\partial u_i}\omega_i,$$

while the ℓ^*-covering is described by the coordinates $p = p_0, p_1, \dots$ satisfying

$$(p_i)_x = p_{i+1}, \qquad p_t = \sum_{i=0}^{k}(-D_x)^i \left(\frac{\partial f}{\partial u_i}p\right).$$

Similar formulas can be obtained for equations of general form.

2.1 Recursion operators for symmetries [7, 13]

Let $\Delta = \nabla = \ell_{\mathscr{E}}$. Then equation (10) takes the form

$$\ell_{\mathscr{E}} \circ V = V' \circ \ell_{\mathscr{E}},$$

i.e., V takes $\ker \ell_{\mathscr{E}}$ (symmetries) to itself. In other words, V is a recursion operator for symmetries. From Theorem 4 we obtain an efficient method to compute such operators:

Corollary 1. *Recursion operators for symmetries are in one-to-one correspondence with fiber-wise linear solutions of the equation $\tilde{\ell}_{\mathscr{E}}(s) = 0$, i.e., with linear shadows in the $\ell_{\mathscr{E}}$-covering.*

Remark 10. Evidently, this result is in full agreement with what we saw in Subsection 1.4.

2.2 Recursion operators for conservation laws [7]

Let $\Delta = \nabla = \ell^*_{\mathscr{E}}$. Then equation (10) takes the form $\ell^*_{\mathscr{E}} \circ V = V' \circ \ell^*_{\mathscr{E}}$, i.e., V takes $\ker \ell^*_{\mathscr{E}}$ (generating functions) to itself. In other words, V is a recursion operator for generating functions. From Theorem 4 we obtain an efficient method to compute such operators:

Corollary 2. *Recursion operators for generating functions are in one-to-one correspondence with fiber-wise linear solutions of the equation $\tilde{\ell}^*_{\mathscr{E}}(s) = 0$, i.e., with nonlocal linear generating functions in the $\ell^*_{\mathscr{E}}$-covering.*

To obtain a recursion procedure for conservation laws, recall that for 'two-line equations' [18–20] their conservation laws (the term $E_1^{0,n-1}$ of the Vinogradov $\mathscr{C}$-spectral sequence) are related to generating functions (the term $E_1^{1,n-1}$) by the injective differential $d_1^{0,n-1}$, which, in the simplest case of evolution equations, coincides with the Euler operator $\mathcal{E}$, and a generating function ψ corresponds to a conservation law if and only if $\ell_\psi = \ell^*_\psi$.

2.3 Hamiltonian structures [7]

Let $\mathscr{E}$ be an evolution equation, $\Delta = \ell^*_{\mathscr{E}}$, and $\nabla = \ell_{\mathscr{E}}$. Then equation (10) takes the form

$$\ell_{\mathscr{E}} \circ V = V' \circ \ell^*_{\mathscr{E}}, \tag{11}$$

i.e., V takes $\ker \ell^*_{\mathscr{E}}$ (generating functions) to $\ker \ell_{\mathscr{E}}$ (symmetries). We call such operators *pre-Hamiltonian*. As above, Theorem 4 provides an efficient method to compute these operators:

Corollary 3. *Pre-Hamiltonian operators are in one-to-one correspondence with fiber-wise linear solutions of the equation $\tilde{\ell}_{\mathscr{E}}(s) = 0$, i.e., with linear shadows in the $\ell^*_{\mathscr{E}}$-covering.*

A pre-Hamiltonian structure is *Hamiltonian* if (a) $V + V^* = 0$ and (b) $[\![s, s]\!]^{\mathrm{s}} = 0$, where $[\![\cdot, \cdot]\!]^{\mathrm{s}}$ is the *variational Schouten bracket* [4]. If $\mathscr{E}$ is of the form

$$u_t = f(x, t, u, \dots, u_k), \qquad u = (u^1, \dots, u^m), \qquad f = (f^1, \dots, f^m), \qquad u_l = \frac{\partial^l u}{\partial x^l}, \tag{12}$$

and $V = \| \sum_l a_{ij}^l D_x^l \|$, where D_x is the total derivative with respect to x, then conditions (a) and (b) can be reformulated in terms of the function[7] $W_V = \sum_{ijl} a_{ij}^l p_l^i p_0^j$ as follows

$$\sum_i \frac{\delta W_V}{\delta p^i} p_0^i = -2W_V, \qquad \mathcal{E} \sum_i \left(\frac{\delta W_V}{\delta u^i} \frac{\delta W_V}{\delta p^i} \right) = 0$$

and are easily checked. Here $\delta/\delta u$, $\delta/\delta p$ are variational derivatives[8].

2.4 Symplectic structures [7]

Let again $\mathscr{E}$ be an evolution equation, $\Delta = \ell_{\mathscr{E}}$, and $\nabla = \ell_{\mathscr{E}}^*$. Then equation (10) takes the form

$$\ell_{\mathscr{E}}^* \circ V = V' \circ \ell_{\mathscr{E}}, \tag{13}$$

i.e., V takes $\ker \ell_{\mathscr{E}}$ (symmetries) to $\ker \ell_{\mathscr{E}}^*$ (generating functions). We call such operators *presymplectic*. Again, Theorem 4 gives an efficient method to compute these operators:

Corollary 4. *Presymplectic operators are in one-to-one correspondence with fiber-wise linear solutions of the equation $\tilde{\ell}_{\mathscr{E}}^*(s) = 0$, i.e., with linear generating functions in the $\ell_{\mathscr{E}}$-covering.*

A presymplectic structure is *symplectic* if condition (a) holds and s is 'variationally closed', that for equation (12) means that

$$\mathcal{E} \sum_i \frac{\delta W_V}{\delta u^i} p_0^i = 0.$$

Remark 11. As it is shown in [8], any skew-adjoint operator V that satisfies the condition (11) *is automatically Hamiltonian*, provided that the symbol of the right-hand side of the corresponding evolution equation is nondegenerate. A similar statement is valid for symplectic structures if we take skew-adjoint solutions of (13).

2.5 Canonical representation for nonlocalities

As it was mentioned above, efficient construction of recursion operators and similar structures needs introduction of nonlocal variables. In all applications we used the following *canonical* choice of nonlocal variables:

for the ℓ-covering: ω_ψ defined by $(\omega_\psi)_x = \psi\omega_0$, where ψ is a generating function, i.e., satisfies the equation $\ell_{\mathscr{E}}^*(\psi) = 0$;

for the ℓ^*-covering: p_φ defined by $(p_\varphi)_x = \varphi p_0$, where φ is a symmetry, i.e., satisfies the equation $\ell_{\mathscr{E}}(\varphi) = 0$.

[7] The variables p_l^i, $l = 0, \dots, k$, $i = 1, \dots, m$, should be *odd*.

[8] In the formula above, as well as in the condition for symplectic structures below, the Euler operator contains variational derivatives both in u and in p.

These nonlocal variables lead to the operators of the form

$$\sum_{\alpha\geq 0} c_{ij}^{\alpha} D_y^{\alpha} + \sum_{\beta} d_j^{\beta} D_y^{-1} \circ e_i^{\beta},$$

where $\left\|c_{ij}^{\alpha}\right\|$ is an $m\times m$-matrix, $\left\|d_j^{\beta}\right\|$ is an $m\times l$-matrix, and $\left\|e_i^{\beta}\right\|$ is an $l\times m$-matrix for some $l>0$ (matrix-valued functions, to be more precise). In the table it is shown how the matrices d and e look for different types of operators.

Type of operator	Lines of matrix d	Columns of matrix e
Recursions for symmetries	Symmetry	Generating function
Recursions for generating functions	Generating function	Symmetry
Hamiltonian structures	Symmetry	Symmetry
Symplectic structures	Generating function	Generating function

2.6 Example: the coupled KdV-mKdV system

We shall now describe a Hamiltonian structure for the coupled KdV-mKdV system of the form

$$\begin{aligned} u_t &= -u_{xxx} + 6uu_x - 3vv_{xxx} - 3v_xv_{xx} + 3u_xv^2 + 6uvv_x,\\ v_t &= -v_{xxx} + 3v^2v_x + 3uv_x + 3u_xv. \end{aligned} \tag{14}$$

This system arises as the so-called *bosonic limit* of the $N=2$, $a=1$ supersymmetric extension of the KdV equation [6]; integrability properties of this system (existence of a recursion operator) were studied in [9]. In [5], by means of the prolongations structure techniques, a Lax pair for (14) was constructed.

2.6.1 Hamiltonian structures

Using the methods described above, we found the following Hamiltonian operator for system (14):

$$V = \begin{pmatrix} -D_x^3 + 4uD_x + 2u_1 & 2vD_x \\ 2vD_x + 2v_1 & D_x \end{pmatrix}. \tag{15}$$

Moreover, the following result is valid:

Theorem 5. *The coupled KdV-mKdV system* (14) *is Hamiltonian with respect to the the Hamiltonian operator* (15) *and possesses the Hamiltonian* $H = \frac{1}{2}(u^2+uv^2-vv_2)$. *The corresponding energy is given by the form*

$$\begin{aligned} \eta = {}& \tfrac{1}{2}\big(u^2+uv^2-vv_2\big)\,dx + \tfrac{1}{2}\big(4u^3+9u^2v^2-2uu_2+3uv^4-11uvv_2+uv_1^2\\ &+u_1^2-u_1vv_1-4u_2v^2-6v^3v_2-3v^2v_1^2+vv_4-v_1v_3+v_2^2\big)\,dt. \end{aligned}$$

This structure is unique in the class of Hamiltonian structures independent of x and t and polynomial in u_k, v_k.

2.6.2 Recursion operators

To describe the recursion operator for (14), let us first introduce the necessary nonlocal variables. They are denoted by w, w_1, w_{11}, w_{12} and defined by the equations

$$w_x = v, \qquad w_t = 3uv + v^3 - v_2;$$

$$
\begin{aligned}
&w_{1,x} = u, \qquad w_{1,t} = 3u^2 + 3uv - u_2 - 3vv_2;\\
&w_{11,x} = \cos(2w)w_1v + \sin(2w)v^2,\\
&w_{11,t} = \cos(2w)(3wuv + wv^3 - wv_2 + uv_1 - u_1v - v^2v_1) + \sin(2w)(4uv^2 + v^4 - vv_2 - v_1^2);\\
&w_{12,x} = \cos(2w)v^2 - \sin(2w)wv,\\
&w_{12,t} = \cos(2w)(4uv^2 - v^4 - 2vv_2 + v_1^2) + \sin(2w)(-3wuv - wv^3 + wv_2 - uv_1 + v^2v_1).
\end{aligned}
$$

Then the recursion operator is given by a 2×2-matrix operator R with the entries

$$
\begin{aligned}
R_{11} &= D_x^2 - 4u - v^2 - Y^u_{1,1}D_x^{-1} \circ \psi^u_{1,2} + Y^u_{1,2}D_x^{-1} \circ \psi^u_{1,1} - \tfrac{3}{2}Y^u_{1,0}D_x^{-1},\\
R_{12} &= 2vD_x^2 + v_1D_x - 3uv + 2v_2 - Y^u_{1,1}D_x^{-1} \circ \psi^v_{1,2} + Y^u_{1,2}D_x^{-1} \circ \psi^v_{1,1} + Y^u_{2,1}D_x^{-1},\\
R_{21} &= -2v - Y^v_{1,1}D_x^{-1} \circ \psi^u_{1,2} + Y^v_{1,2}D_x^{-1} \circ \psi^u_{1,1} - \tfrac{3}{2}Y^v_{1,0}D_x^{-1},\\
R_{22} &= D_x^2 - 2u - v^2 - Y^v_{1,1}D_x^{-1} \circ \psi^v_{1,2} + Y^v_{1,2}D_x^{-1} \circ \psi^v_{1,1} + Y^v_{2,1}D_x^{-1},
\end{aligned}
$$

where $Y_{1,0}$, $Y_{1,1}$, $Y_{1,2}$, and $Y_{2,1}$ are symmetries of (14) with the components

$$
\begin{aligned}
&Y^u_{1,0} = u_1, \qquad Y^v_{1,0} = v_1;\\
&Y^u_{1,1} = -\cos(2w)\left(\tfrac{1}{2}u_1 + vv_1\right) + \sin(2w)\left(uv - \tfrac{1}{2}v_2\right), \qquad Y^v_{1,1} = \tfrac{1}{2}\cos(2w)v_1 - \tfrac{1}{2}\sin(2w)u;\\
&Y^u_{1,2} = \cos(2w)(uv - \tfrac{1}{2}v_2) + \sin(2w)\left(\tfrac{1}{2}u_1 + vv_1\right), \qquad Y^v_{1,2} = -\tfrac{1}{2}\cos(2w)u - \tfrac{1}{2}\sin(2w)v_1;\\
&Y^u_{2,1} = \cos(2w)(-w_{11}u_1 - 2w_{11}vv_1 + 2w_{12}uv - w_{12}v_2)\\
&\qquad + \sin(2w)(2w_{11}uv - w_{11}v_2 + w_{12}u_1 + 2w_{12}vv_1) - 2uv_1 - 3u_1v - 2v^2v_1 + v_3,\\
&Y^v_{2,1} = \cos(2w)(w_{11}v_1 - w_{12}u) - \sin(2w)(w_{11}u + w_{12}v_1) - (u_1 + vv_1),
\end{aligned}
$$

while

$$
\begin{aligned}
&\psi^u_{1,1} = -\sin(2w), \qquad \psi^v_{1,1} = 2(2\sin(2w)v - w_{12});\\
&\psi^u_{1,2} = -\cos(2w), \qquad \psi^v_{1,2} = 2(2\cos(2w)v + w_{11}).
\end{aligned}
$$

are the generating functions (cf. the remark above on the canonical representation of nonlocal objects).

2.7 Back to Bäcklund transformations

The above described scheme needs one generalization at least. Since recursion operators arising in practice usually contain terms of the D_x^{-1} type, these nonlocalities should be added in the initial setting[9]. This is being done by substituting equation $\mathscr{E}$ with its covering $\tilde{\mathscr{E}}$ in all constructions. Consequently, the operators obtained cease to be differential, but can be transformed to *$\mathscr{C}$-differential relations* between the objects where they act. Geometrically, these relations are realized as Bäcklund transformations relating:

- $\ell_{\mathscr{E}}$-covering with itself (recursion operators for symmetries);
- $\ell^*_{\mathscr{E}}$-covering with itself (recursion operators for generating functions);
- $\ell_{\mathscr{E}}$-covering with $\ell^*_{\mathscr{E}}$ covering (pre-Hamiltonian and presymplectic structures).

The first step in this direction was made in [16], where recursion operators for symmetries were treated as Bäcklund transformations. Clearly, generalized recursion operators for generating functions can be constructed in a similar way. As for the third type of Bäcklund transformations, one can see that they unify the concepts of pre-Hamiltonian and presymplectic structures. Following [2], these transformations may be called *pre-Dirac structures*. Their study is a subject for future research.

[9] Such terms arise also in *nonlocal* Hamiltonian and symplectic structures.

The general self-consistent approach for calculating of spectral parameters of the one-dimensional Schrödinger operator with the finite-gap Abelian potential is proposed. It is based on use of finite-band equations and solution of the Jacobi inverse problem in terms of hyperelliptic Weierstrass functions.

1 Introduction

General solutions of completely integrable systems are expressed in terms of the Riemann theta functions containing unknown parameters. Obtaining these solutions in an explicit form is reduced to the problem of calculation of the mentioned parameters. Usually, solving of this problem is realized in the framework of two following approaches. The first algebro-geometric approach is based on an use of the so-called Thomae formulae describing relations between the unknown parameters and so-called theta-constants (see [1–3]). In so doing, it is assumed that spectral branch points are given, and their calculation is a special problem. Role of independent parameters in this formulae is played by the period matrix τ generated by the hyperelliptic Riemann curve $\Gamma_g : y^2 = \prod_{i=1}^{2g+1} (\varepsilon - \varepsilon_i)$ (see [2]). The second approach is based on construction of algebraic equations for the unknown parameters by forward substitution of the general solutions in to an original integrable equation (see [3]). These two approaches assume that the explicit form of the generated Riemann curve is given and do not provide their calculation.

In the same time, the full and self-consistent solving of the considered problem assumes construction of a unique system of equations determining all unknown parameters. This can be realized in the form of so-called finite-band equations in the framework of the spectral problem for auxiliary linear operators (see [4–7]) corresponding to a given integrable equation.

In the case of the KdV equation under consideration this problem is connected with the spectral problem for the finite-gap Schrödinger operator. In the presented paper the effective method for full solving of the spectral problem for the one-dimensional Schrödinger operator is proposed on the basis of finite-band equations. As distinct from the above-mentioned second approach, the substitution of solutions (the Schrödinger potential) is realized with respect to the finite-band equations. In so doing, the problem is reduced to solving of a self-consistent system of algebraic equations determining all unknown parameters through theta-constants (see [1]). This provides calculation of both parameters of the potential and spectral parameters of the Schrödinger operator.

The presented paper consists of three sections. General analytic solving of the spectral problem for the finite-gap Schrödinger operator in terms of hyperelliptic Weierstrass functions is considered in Section 2. In Section 3 we obtain the system of algebraic equations for the unknown parameters including spectral parameters and consider particular cases of one- and two-gap spectra.

2 Finite-gap solutions

Eigenfunctions of linear differential operators with a finite-gap spectrum are characterized by their dependence on a spectral variable ε through polynomials in ε [5]. Therefore solving of the corresponding spectral problem is based on the comparison of asymptotic expansions in ε of general and finite-gap eigenfunctions. This is expressed in the form of so-called finite-band equations describing all unknown parameters of finite-gap solutions.

The spectral equation ($H\Psi = \varepsilon\Psi$) of the general and finite-gap one-dimensional Schrödinger operator (H) determines its eigenfunction in the form

$$\Psi_{\pm}(x) = C\sqrt{\chi(\varepsilon,x)}\exp\left(\pm\imath\int_{x_0}^{x} dx\chi(\varepsilon,x)\right)$$

with $\chi(\varepsilon,x)$ determined by the general spectral equation and $\chi(\varepsilon,x) = y(\varepsilon)/X(\varepsilon,x)$ for the finite-gap spectra. Here polynomial functions $y(\varepsilon)$ and $X(\varepsilon,x)$ are of $(2g+1)$-th and g-th orders in ε, respectively. Here the X-polynomial is characterized by a dependence on x of coefficients at powers of ε.

The function $X(\varepsilon,x)$ is the product of two eigenfunctions ($X(\varepsilon,x) = \Psi_+(\varepsilon,x)\Psi_-(\varepsilon,x)$) and satisfies to the equation, which in terms of X-polynomial roots $\mu_j(x)$ take the form (see [8])

$$\partial_x X(\varepsilon,x)|_{\varepsilon=\mu_j(x)} = 2\imath y(\mu_j(x)).$$

This equation is integrated by the Abelian map $\zeta_j = \sum\limits_{k=1}^{g}\int_{a_k}^{\mu_k(x)} dv_j(\varepsilon)$, where $dv_j = \sum\limits_{i=1}^{g} C_{ij}d\omega_i$ is normalized holomorphic differential on the Riemann curve Γ_g: $y^2 = \prod\limits_{i=1}^{2g+1}(\varepsilon-\varepsilon_i)$ and $d\omega_j = \varepsilon^{j-1}d\varepsilon/y(\varepsilon)$. Corresponding solutions have the form $\zeta_j = 2\imath C_{gj}x$. Thus calculation of symmetrized products of the set $\{\mu_j(x)\}$ is reduced to inverse of the Abelian map (see for instance [1, 2]). Symmetrized products of $\{\mu_j(x)\}$, considered as the point set on the Riemann curve Γ_g, can be calculated with help of the Riemann theta functions

$$\theta[\boldsymbol{\alpha}](\boldsymbol{z}|\boldsymbol{\tau}) = \sum_{n\in\mathbb{Z}^g}\exp[\pi\imath(\boldsymbol{n}+\boldsymbol{\alpha}_1)\tau(\boldsymbol{n}+\boldsymbol{\alpha}_1)+2\pi\imath\boldsymbol{z}\cdot(\boldsymbol{n}+\boldsymbol{\alpha}_2)], \tag{1}$$

where

$$\boldsymbol{z} = \int_{x_0}^{x} d\boldsymbol{\omega} - \boldsymbol{C}\boldsymbol{u} - \boldsymbol{K}, \qquad u_j = \sum_{k=1}^{g}\int_{a_k}^{x_k} d\omega_j(x)$$

which vanish in points $\{\mu_j(x)\}$.

Here α is the $2\times g$ half-integer matrix with rows represented by vectors α_1 and α_2; τ is the period matrix on the Riemann curve Γ_g, $\boldsymbol{K}$ is a so-called Riemann constant vector.

In the framework of the Kleinian construction (see [9]) the so-called hyperelliptic σ-function

$$\sigma(\boldsymbol{u}) = C\exp\left(\boldsymbol{u}\boldsymbol{\kappa}\boldsymbol{u}+2\pi\imath\boldsymbol{q}'(-\boldsymbol{C}\boldsymbol{u}+\boldsymbol{r}\boldsymbol{q}'/2-\boldsymbol{q}')\right)\theta\left(\int_{x_0}^{x}\boldsymbol{C}d\omega-\boldsymbol{C}\boldsymbol{u}-\boldsymbol{K}|\boldsymbol{\tau}\right), \tag{2}$$

plays the role of the generating functions for hyperelliptic Abelian functions. Absence of $\theta(z)$ implies the function (1) at $\alpha = 0$.

Here $\boldsymbol{r}_j$ is determined by the expression $dr_j = r_j dx$ ($r_j = \sum\limits_{k=j}^{2g+1-j}(k+1-j)\lambda_{k+1+j}x^k/2y$), which describes canonical Abelian differential of second kind on the Riemann curve Γ_g; $\boldsymbol{q}'$ and $\boldsymbol{q}$ are half-integer characteristics of the Riemann constant vector $\boldsymbol{K}$.

Hyperelliptic zeta and Weierstrass functions are defined as logarithmic derivatives of the function (2) by the formulae

$$\zeta_{j_1}(u) = \frac{\partial}{\partial u_{j_1}} \ln \sigma(\boldsymbol{u}), \qquad \wp_{j_1 j_2 \cdots j_n}(\boldsymbol{u}) = -\frac{\partial^{j_1+j_2+\cdots+j_n}}{\partial u_{j_1} \partial u_{j_2} \ldots \partial u_{j_n}} \ln \sigma(\boldsymbol{u}), \quad n \geq 2. \tag{3}$$

The Weierstrass functions in (3) implicitly contain unknown parameters $\{C_{ij}\}$ and the period matrix $\boldsymbol{\tau}$ as an independent parameter. Taking into account the dependence of $\boldsymbol{u}$ on points $\{x_i\}$ on the Riemann curve Γ_g it is see that second derivative of the σ-function (2) represents a polynomial in x_i with coefficient functions $\wp_{j_1 j_2}(\boldsymbol{u})$. Evidently the equality for a such polynomial enable to determine symmetrized products of $\mu_j(x)$ through hyperelliptic functions $\wp_{j_1 j_2}(\boldsymbol{u})$, which, with account of above-mentioned relations between vectors $\boldsymbol{\zeta}$ and $\boldsymbol{u}$, will contain unknown parameters C_{ij}.

This equality can be obtained on the basis of the known Baker relation (see [9])

$$\int_\nu^x \sum_{i=1}^g \int_{\nu_i}^{x_i} d\Omega(x, x_i) = \ln \left(\sigma \left(\int_{x_0}^x d\omega - \sum_{i=1}^g \int_{x_0}^{x_i} d\omega \right) \sigma^{-1} \left(\int_{x_0}^x d\omega - \sum_{i=1}^g \int_{x_0}^{\nu_i} d\omega \right) \right) \Bigg|_{x=\nu}^x, \tag{4}$$

where the fundamental 2-differential of the second kind $d\Omega(x, x_i)$ is defined by the expression

$$d\Omega(x, x_i) = \frac{\partial}{\partial_x} \left(\frac{y(x) + y(x_i)}{2y(x)(x - x_i)} \right) dx dx_i + d\omega(x) d\boldsymbol{r}(x_i).$$

The partial derivation of (4) with respect to x and x_k taking into account the definition (3) leads to the relation

$$\sum_{i,j=1}^g \wp_{ij} \left(\int_{x_0}^x d\omega - \sum_{i=1}^g \int_{x_0}^{x_i} d\,\omega \right) x^i x_k^j = \frac{F(x, x_k) - 2y y_k}{4(x - x_k)^2}, \tag{5}$$

with known [9] F-function which has the form of polynomial in variables x and x_k. Using the known relation $F(x, x_k) \to x^{g+1} x_k^{g+1}$ at $x \to \infty$ from (5) in the asymptotic limit $x \to \infty$ we obtain the equation

$$x_k^g - \sum_{j=1}^g \wp_{g,g+1-j}(\boldsymbol{u}) x_k^{g-j} = 0. \tag{6}$$

In view of (6) the coefficient function $\wp_{g,g+1-j}(u)$ equals to the symmetrized product of a j degree of the above mentioned point set $\{x_k\}$ of the Riemann curve Γ_g. This is true also with respect to the point set $\{\mu_k(x)\}$.

Thus coefficient functions $b_j(x)$ are expressed through generalized Weierstrass $\wp$-functions by the relation

$$b_j(x) = -\wp_{g,g+1-j}(\boldsymbol{u}). \tag{7}$$

In terms of the above-mentioned normalized vectors $\zeta = \boldsymbol{C}\boldsymbol{u}$ belonging to Abelian map on the basis of the normalized first-kind Abelian holomorphic differentials v, the relation (6) takes the form

$$b_j(x) = -\sum_{n,m=1}^g C_{gn} C_{g,g+1-j} \wp_{nm}(\boldsymbol{\alpha} x), \qquad (\boldsymbol{\alpha})_j = C_{gj}. \tag{8}$$

Thus the spectral problem for the one-dimensional Schrödinger operator with a finite-gap spectrum is reduced to calculation of the normalized coefficient matrix C. Normalized coefficients in (8) are described by algebraic equations, which can be obtained by substitution of the expression (8) into known finite-band equations with transition to the theta function representation.

3 Calculation of unknown parameters

The system of finite-band equations represents relations between coefficient functions $b_j(x)$ and polynomials in derivatives of the Schrödinger potential $U(x)$ with respect to x. This system follows from comparison of asymptotic expansions in ε for general and finite-gap χ-functions entering in the above-mentioned expression for the eigenfunction $\Psi(\varepsilon, x)$ of the Schrödinger spectral equation (see [4]).

For the general solution, coefficients of the power expansion

$$\chi = \sqrt{\varepsilon}\left(1 + \sum_{n=0}^{\infty}\left((-1)^n/2^{2n+1}\right)\chi_{2n+1}\varepsilon^{-(n+1)}\right)$$

are polynomial in derivatives of $U(x)$. For the finite-gap solutions, coefficients of the power expansion $\chi(\varepsilon, x) = y(\varepsilon)/X(\varepsilon, x)$ are represented polynomial in spectral coefficients $\{a_j\}$ and coefficient functions $b_j(x)$. Comparison of power expansions for both cases leads to the so-called finite-band system of equations

$$\begin{aligned}
&\frac{1}{n!}\frac{\partial^n}{\partial_z^n}\left(\frac{\left(\sum\limits_{k=0}^{2g+1} a_k z^k\right)^{1/2}}{\sum\limits_{k=0}^{g} b_k(x) z^k}\right)_{z=0} = \frac{(-1)^{n-1}}{2^{2n-1}}\chi_{2n-1}(x), \qquad a_0, b_0 = 1,\\
&\chi_{n+1} = \frac{\partial}{\partial_x}\chi_n + \sum_{k=1}^{n-1}\chi_k\chi_{n-k}, \qquad \chi_1 = -U(x),
\end{aligned} \tag{9}$$

in which $b_k(x) = 0$ at $k > g$. Feature of this equations is that the coefficient function $b_j(x)$ enters linearly to each equation (9) at $n = j$ and is algebraically expressed through all previous coefficient functions $b_i(x)$, $i = \overline{1, j-1}$. The same regularity takes place for spectral parameters a_j at $j > g$.

Therefore all coefficient functions b_j at $j \le g$ are expressed as polynomials in derivatives of potential $U(x)$. The system of spectral parameters a_j at $j = \overline{g+1, 2g+1}$ is algebraically expressed through first g parameters $a_1, \ldots, a_g$ and polynomials in derivatives $U^{(i)}$.

Thus, use of an eliminating method concerning a_j and $b_j(x)$ reduces equations (9) at $n = \overline{2g+2, 3g+1}$ to the closed system (RS) of algebraic equations for g unknowns a_j, $j = \overline{1, g}$.

The potential $U(x)$ in (9) is connected with the coefficient function $b_1(x)$ by the relation

$$b_1(x) = \frac{1}{2}\left(U(x) + a_1\right),$$

which together with the equality (7) result in the explicit expression

$$U(x) = -2\sum_{j,j'=1}^{g}\alpha_j\alpha_{j'}\wp_{jj'}(\boldsymbol{\alpha}x|\boldsymbol{\tau}) - a_1. \tag{10}$$

describing the Schrödinger potential in terms of generalized Weierstrass $\wp$-functions at the given module matrix $\boldsymbol{\tau}$ of the Riemann curve Γ (in future for simplicity $\boldsymbol{\tau}$ will be omitted). Here components α_j, $j = \overline{1, g}$ must be calculated from the above-mentioned reduced system.

Substitution of the expression (10) into equations (9) results in a system of nonlinear equations for unknowns a_j, $j = \overline{1, 2g+1}$ and α_j, $j = \overline{1, g}$ with coefficients expressed through derivatives of $\wp$-function with respect to x. In view of independence on x this system is represented by algebraic nonlinear equations with respect to a_j and α_j. In representation of above-mentioned

theta functions such system is reduced to algebraic nonlinear equations with coefficients which are expressed through theta-constants (i.e. theta functions with zero argument). Correspondingly, the above-mentioned RC system is transformed in to the algebraic system of equations concerning unknowns a_j and α_j at $j=\overline{1,g}$.

For obtaining above-mentioned equations it is convenient to introduce j-component vector $\boldsymbol{n}_j=(n_1,\dots,n_j)$ and notations $\alpha_{\boldsymbol{n}_j}=2\prod\limits_{\boldsymbol{n}_i=1}^{j}\alpha_{n_i}$ and $\wp_{\boldsymbol{n}_j}=\wp_{n_1\cdots n_j}$. Then the expression (10) can be rewritten more compactly as

$$U(x)=\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}}(\boldsymbol{\alpha}x)-a_1, \tag{11}$$

where summing by repetitive subscript components is implied.

Substitution of the expression (11) into the equations (9) results in the equation

$$\begin{aligned} b_2(x)=&\frac{1}{8}\big(3\left(\alpha_{\boldsymbol{n}_2g}\wp_{\boldsymbol{n}_2}-a_1\right)^2-\left(\alpha_{\boldsymbol{n}_4g}\wp_{\boldsymbol{n}_4}\right)\big)\\ &-\frac{1}{4}a_1\left(\alpha_{\boldsymbol{n}_2g}\wp_{\boldsymbol{n}_2}-a_1\right)+\frac{1}{2}a_2-\frac{1}{8}a_1^3 \end{aligned} \tag{12}$$

and

$$\begin{aligned} b_3(x)=&\frac{1}{32}\big(\alpha_{\boldsymbol{n}_4g}\wp_{\boldsymbol{n}_4}+10\left(\alpha_{\boldsymbol{n}_2g}\wp_{\boldsymbol{n}_2}-a_1\right)^3-5\left(C_{\boldsymbol{n}_3g}\wp_{\boldsymbol{n}_3}\right)^2\\ &-10\left(\alpha_{\boldsymbol{n}_2g}\wp_{\boldsymbol{n}_2}-a_1\right)\alpha_{\boldsymbol{n}_4g}\wp_{\boldsymbol{n}_4}\big)-\frac{1}{16}a_1\big(3\left(\alpha_{\boldsymbol{n}_2g}\wp_{\boldsymbol{n}_2}-a_1\right)^2-\alpha_{\boldsymbol{n}_4g}\wp_{\boldsymbol{n}_4}\big)\\ &+\frac{1}{16}(\alpha_{\boldsymbol{n}_2g}\wp_{\boldsymbol{n}_2}-a_1)\left(a_1^2-4a_2\right)+\frac{1}{2}a_3+\frac{1}{4}a_1a_2+\frac{1}{16}a_1^3. \end{aligned} \tag{13}$$

Finite-gap equations (12), (13) and of higher order are valid with any arguments of generalized Weierstrass $\wp$-functions. Therefore these equations can be represented in terms of theta-constants (theta-functions on zero argument) by the formal substitute

$$\wp_{\boldsymbol{n}_j}\to(\ln\theta)_{\boldsymbol{n}_j},\qquad(\ln\theta)_{\boldsymbol{n}_j}=\partial_{n_1,\dots,n_j}\ln\theta(z|\boldsymbol{\tau})_{z=0}). \tag{14}$$

In the case of the one-gap spectrum, the generalized Weierstrass functions transform in to the elliptic Weierstrass function ($\wp_{\boldsymbol{n}_j}\to\wp_{11}$) and $\alpha_1=1$. In this case $b_j(x)=0$ at $j>1$. Therefore reducing in (12) and (13) similar terms and vanishing coefficients at degrees of $\wp_{11}$ we immediately obtain the following solutions for spectral parameters a_1, a_2, a_3

$$\begin{aligned} &a_1=0,\qquad a_2=\wp(\omega_1)\wp(\omega_2)+\wp(\omega_1)\wp(\omega_3)+\wp(\omega_2)\wp(\omega_3),\\ &a_3=\wp(\omega_1)\wp(\omega_2)\wp(\omega_3),\qquad \omega_1=\omega,\qquad \omega_2=\omega+\omega',\qquad \omega_3=\omega', \end{aligned}$$

where ω and ω' are real and imaginary self-periods of the elliptic Weierstrass function.

In the two-gap case ($g=2$) normalized constants $\{C_j\}$ are not known and are determined by equations (13) and (14). Unknowns a_j, α_j, $j=1,2$ are solutions of the above-mentioned RC system (corresponding to (9) at $n=\overline{6,9}$). This system takes the form of algebraic nonlinear equations which can be written as

$$\begin{aligned} 0=&B_{610}^{22}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2^2+B_{61j}^{21}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2a_1^j|_0^1+B_{61j}^{20}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_1^j|_0^4,\\ 0=&B_{71j}^{22}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2^2a_1^j|_0^1+B_{71j}^{21}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2a_1^j|_0^3+B_{71j}^{20}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_1^j|_0^5,\\ 0=&B_{810}^{23}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2^3+B_{81j}^{22}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2^2a_1^j|_0^2+B_{81j}^{21}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2a_1^j|_0^4+B_{81j}^{20}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_1^j|_0^6,\\ 0=&B_{91j}^{23}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2^3a_1^j|_0^1+B_{91j}^{22}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2^2a_1^j|_0^3\\ &+B_{91j}^{21}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_2a_1^j|_0^5+B_{81j}^{20}(\alpha_{\boldsymbol{n}_2}\wp_{\boldsymbol{n}_2})a_1^j|_0^8, \end{aligned}$$

where summing by repetitive subindexes in boundaries which are denoted at vertical hyphens is implied. Also the formal transfer (14) is suggested. Here $B_{m1j}^{2i}(z)$ implies coefficient function at $a_2^i a_1^j$ corresponding to the equation (9) at $n = m$. This coefficient function is a polynomial in derivatives of its argument with respect to x and therefore contains terms $\partial_x^k \wp_{\boldsymbol{n}_2} = \alpha_{\boldsymbol{n}_{2+k}} \wp_{\boldsymbol{n}_{2+k}}$ in accordance with (11). The latter system is represented by the closed system of the four algebraic nonlinear equations which determines two spectral parameters a_1, a_2 and components α_1, α_2. The remaining unknowns a_j, $j = \overline{3,5}$ are calculated by forward substitution of obtained a_1, a_2 and α_1, α_2 into the reduced equations (9) at $n = \overline{3,5}$. In so doing, the matrix $\boldsymbol{\tau}$ plays a role of a independent parameter.

Similar calculation can be applied in the case of the arbitrary number of spectral gaps in the spectrum of the one-dimensional Schrödinger operator. Then unknown spectral parameters $a_1, \ldots, a_g$ and the parameters $\alpha_1, \ldots, \alpha_g$ will be determined by reduced equations a system of $2g$ reduced algebraic equations (9) at $n = \overline{2g+2, 4g+1}$. The rest spectral parameters a_j, $j = \overline{g+1, 2g+1}$ will be calculated by forward substitution of computed $a_1, \ldots, a_g$ and $\alpha_1, \ldots, \alpha_g$ into the reduced equations (9) at $n = \overline{g+1, 2g+1}$.

The general reduced algebraic equations are represented by the necessary conditions that the Riemann τ-matrix will be the period matrix of holomorphic differentials on the Riemann curve Γ. Thus there are no restrictions on the number of gaps in spectra.

The suggested finite-gap method gives simple and common algorithm for solving the spectral problem for the finite-gap Schrödinger operator. This problem is reduced to calculation of the closed system of algebraic nonlinear equations. The method is represented by the hyperelliptic generalization of the earlier suggested approach [10] for solution of the spectral problem in the one-gap case for the one-dimensional elliptic Schrödinger operator.

The paper concerns the study of rational and logarithmic reductions of the 2D dispersionless Toda hierarchy of integrable equations. The subject is motivated by important applications to problems in interface dynamics and statistical physics. We prove the consistency of such reductions with respect to the "Toda–Krichever" flows of the 2dToda hierarchy constrained by a string equation.

1 Introduction

Our paper concerns with the study of rational solutions of the dToda hierarchy of integrable equations. The subject is motivated by numerous important applications to problems of interface dynamics and statistical physics. We outline them briefly in this section and widen the discussion in the summary of [1] of the present volume.

The Laplacian growth is a process of propagation of a boundary between two phases on the plane [6, 4]. The both phases are described by scalar harmonic fields (e.g. electrostatic potential, density or pressure), while the speed of the interface is proportional to the gradient of the difference between the fields. In the case where the boundary is an analytic curve it is usual to introduce a time-dependent conformal mapping from the exterior of the unit circle in the "mathematical" (w) plane $z = z(w, x)$, $w = \exp(\sqrt{-1}\phi)$, $0 < \phi < 2\pi$ to the boundary curve $z = X + \sqrt{-1}Y$ on the "physical" plane. It is shown in [6, 7, 4] that the Laplacian growth problem is equivalent to solution of the following equation

$$\mathrm{Im}\left(\frac{\partial z}{\partial \phi}\frac{\partial \bar{z}}{\partial x}\right) = w\left(\frac{\partial z(w,x)}{\partial w}\frac{\partial \bar{z}(1/w,x)}{\partial x} - \frac{\partial z(w,x)}{\partial x}\frac{\partial \bar{z}(1/w,x)}{\partial w}\right) = 1, \tag{1}$$

where bar stands for the complex conjugation (and $\bar{w} = w^{-1}$ at the curve). Equation (1) is called the Laplacian Growth equation [8, 7].

It turns out that (1) plays an essential role in the theory of infinite-dimensional integrable hierarchies. In particular, the equivalence of the contour dynamics to the dispersionless limit of the integrable Toda hierarchy constrained by (1) was established in [4]. Equation (1) may be interpreted as a constraint on an infinite commuting set of dynamical systems defined in the space of one-parameter families of conformal maps. This constraint characterizes the fixed points of an "additional symmetry" [5] in which x is interpreted as the flow parameter.

In what follows, we consider finite-dimensional solutions of (1) in a context of 2dToda hierarchy of integrable equations. We study formal algebraic solutions of the problem, forgetting about complex structure and treating z, $\bar{z}$ as independent functions, and w as a formal variable.

2 Reductions of 2dToda hierarchy constrained by string equation

2.1 2dToda hierarchy and string equation

The dToda hierarchy is defined in terms of two functions $z(w,x)$ and $\bar{z}(w^{-1},x)$ of the form:

$$z(w,x)=r(x)w+\sum_{k=0}^{\infty}u_k(x)w^{-k},\qquad \bar{z}\left(w^{-1},x\right)=r(x)w^{-1}+\sum_{k=0}^{\infty}\bar{u}_k(x)w^{k}, \tag{2}$$

where the coefficients $r(x)$, $u_k(x)$, $\bar{u}_k(x)$ are viewed as coordinate functionals on the phase space consisting of such pairs $z(w,x)$, $\bar{z}(w^{-1},x)$. The dToda flow equations are

$$\partial_{t_k}z=\{H_k,z\},\qquad \partial_{\bar{t}_k}\bar{z}=\{\bar{H}_k,\bar{z}\},\qquad \partial_{t_k}\bar{z}=\{H_k,\bar{z}\},\qquad \partial_{\bar{t}_k}z=\{\bar{H}_k,z\}, \tag{3}$$

$$H_k=(z^k)_+ +1/2\big(z^k\big)_0,\qquad \bar{H}_k=\big(\bar{z}^k\big)_- +1/2\big(\bar{z}^k\big)_0 \tag{4}$$

with subscripts $\pm$, 0 denoting the negative/positive and zero parts of the formal Laurent expansion in w. The Poisson–Lax bracket notation here stays for

$$\{f,g\}:=w\frac{\partial f}{\partial w}\frac{\partial g}{\partial x}-w\frac{\partial f}{\partial x}\frac{\partial g}{\partial w}. \tag{5}$$

The dispersionless limit of the "string equation" is the constraint

$$\left\{z(w,x),\bar{z}\left(w^{-1},x\right)\right\}=1. \tag{6}$$

Equation (6) is invariant under (3) and so defines an invariant under the dToda flows (3) manifold and a reduction of the full dToda hierarchy. The reduction of the dToda hierarchy by the string equation is still an infinite, compatible set of infinite-dimensional dynamical systems. In what follows we are interested in further "functional" reductions where z, $\bar{z}$ are polynomial, rational or logarithmic functions of w. As we show below such reductions are consistent with 2D dToda flows (3) if the string equation (6) holds. Thus, for the consistency we need a double ("functional" plus "string") reduction, which defines a finite-dimensional invariant sub-manifold on the phase space of general 2d Toda hierarchy.

2.2 Polynomial reductions

We begin with polynomial reductions of the 2D Toda chain

$$z(w)=rw+\sum_{i=-N}^{0}u_iw^i,\qquad \bar{z}\left(w^{-1}\right)=rw^{-1}+\sum_{i=0}^{N}\bar{u}_iw^i \tag{7}$$

constrained by the string equation (6). The following proposition states consistency of the polynomial reductions under the Toda flows:

Proposition 1. *If the string equation* (6) *holds, then* (7) *belong to a manifold invariant under the 2dToda flows* $\partial/\partial t_i$, $\partial/\partial\bar{t}_i$, $0<i<N+2$ (3). *This manifold has dimension* $2N+3$ *with* $r=r(T)$, $u=u(T)$, $\bar{u}=\bar{u}(T)$, $T=\{t_i,\bar{t}_i\}$, $i=1,\dots,2N+1$ *being solution of the dynamical system induced by 2dToda flows* (3).

Proof. We must prove that z remains of the form (7) under the flows generated by H_k, $\bar{H}_k$ provided the string equation (6) holds. (The proof for $\bar{z}$ is similar).

1. First we proceed with the flows generated by H_k. The lowest degree of z is $-N$. Since

$$H_k = \left(z^k\right)_+ + 1/2\left(z^k\right)_0 = h_k w^k + h_{k-1}w^{k-1} + \cdots + h_0 \tag{8}$$

is a Laurent polynomial of positive degree, the lowest degree term in the bracket $\{z, H_k\}$ is not less than $-N$. Therefore the lowest degree term in z remains $\geq -N$ under the flows. On the other hand, the complement $z^k - H_k$ of (8) is a polynomial in $1/w$ and so, $\{H_k, z\} = -\{z^k - H_k, z\}$ is a Laurent polynomial with the highest degree in w not exceeding 1. Therefore the highest degree term in z remains ≤ 1.

2. Unlike the evolution under the H_k-flows, the form-invariance (7) of z under the flows generated by the $\bar{H}_k$'s requires extra restrictions on the derivatives $\partial_{t_k} u_i$, stemming from the string equation. Since $\bar{H}_k = (\bar{z}^k)_- + 1/2(\bar{z}^k)_0$ is a Laurent polynomial of non-positive degree, we again see that the highest degree in $\{z, H_k\}$ is 1, and hence this degree cannot increase under the flow. However, since $\bar{H}_k = \bar{z}^k - ((\bar{z}^k)_+ + 1/2(\bar{z}^k)_0)$ is the difference between $\bar{z}^k$ and a polynomial of nonnegative degree, $\{\bar{H}_k, z\} = \{\bar{z}^k, z\} - \{((\bar{z}^k)_+ + 1/2(\bar{z}^k)_0), z\}$, the second bracket in this expression has lowest degree $\geq -N$, but not, in general, the first. However, since $\{\bar{z}^k, z\} = k\bar{z}^{k-1}\{\bar{z}, z\}$, imposing the extra restriction (6) (string equation), again implies that the lowest degree term in this bracket does not exceed $-N$, provided $k \leq N+1$. ■

2.3 Rational reductions

Consider now the space of rational functions $z(w)$ and $\bar{z}(w)$ of the form

$$z(w) = \frac{q_{N+1}(w)}{p_N(w)} = \frac{r w^{N+1} + \sum_{i=0}^{N} a_i w^i}{w^N + \sum_{i=0}^{N-1} b_i w^i}, \tag{9}$$

$$\bar{z}(w^{-1}) = \frac{\bar{q}_{N+1}(w^{-1})}{\bar{p}_N(w^{-1})} = \frac{r w^{-(N+1)} + \sum_{i=0}^{N} \bar{a}_i w^{-i}}{w^{-N} + \sum_{i=0}^{N-1} \bar{b}_i w^{-i}}, \tag{10}$$

where the $4N+3$ coefficients r, a_i, $\bar{a}_i$, b_i, $\bar{b}_i$ are functions of x. The following Lemma states onvariance of such rational reductions of $z(w)$ and $\bar{z}(w)$ under the dToda flows.

Lemma 1. *The space of functions $z(w)$ of the form* (9) *is invariant under the dToda flows ∂_{t_i}, $i > 0$. and, similarly, the space of functions $\bar{z}(w^{-1})$ of the form* (10) *is invariant under the $\partial_{\bar{t}_i}$, $i > 0$ flows.*

Proof. Consider the flows generated by H_k. The proof for $\bar{z}$ is similar. Since

$$H_k = \left(z^k\right)_+ + 1/2\left(z^k\right)_0 \tag{11}$$

is a polynomial of nonnegative degree in w, its complement $z^k - H_k$ is a polynomial in $1/w$. Then the Laurent expansion of brackets (5) $\{H_k, z\} = -\{z^k - H_k, z\}$ around infinity has the following form

$$\{H_k, z\} = k_1(T)w + k_0(T) + k_{-1}(T)w^{-1} + \cdots . \tag{12}$$

While the Lax bracket (5) implies that it is rational of the form $\{H_k, z\} = Q(w)/p_N(w)^2$, it follows from (12) that the highest degree in polynomial $Q(w)$ does not exceed $2N+1$. On the other hand, since it is clear that $\partial_{t_k} z = P(w)/{p_N}^2(w)$, $P(w) = p_N \partial_{t_k} q_{N+1} - q_{N+1}\partial_{t_k} p_N$,

where the highest degree in the polynomial $P(w)$ also does not exceed $2N+1$, we may therefore equate to zero the coefficients of polynomial $P(w)-Q(w)$, and thereby get a system of differential equations for r, a, b. The number of equations obtained is $2N+2$. Thus we get a compatible system of differential equations for $2N+2$ unknowns r, a, b. ■

The consistency of rational solutions for the whole Toda hierarchy requires some extra restrictions. This is the point where the string equation plays an essential role.

Proposition 2. *The string equation* (6) *is a sufficient condition for the rational functions* $z(w)$ *and* $\bar{z}(w)$ (9), (10) *to belong to a manifold, which is only invariant under the first two-Toda flows* $\partial/\partial t_1$, $\partial/\partial \bar{t}_1$ *(see* (3)*).*

Proof is by argument similar to those used for Lemma (1) and Proposition (1).

So, there are only two flows compatible with the rational ansatz. In fact, we could not expect more invariant flows associated to the two simple poles at $w=0$ and $w=\infty$. In the polynomial case, the number of invariant flows was equal to the number of variables (polynomial coefficients), since one can associate n invariant flows to the pole of the n th order, and poles at zero and infinity are immovable. Below, we introduce additional flows, related to movable singularities of $z(w)$ and $\bar{z}(w^{-1})$ using a result by Krichever.

2.4 Additional flows for rational reductions of the dKP hierarchy

As mentioned in [2], on the phase space of extended Benney systems, i.e. rational dKP reductions admitting poles of arbitrary degree, there arise some new flows related to the pole structure of the corresponding maps. These additional flows were introduced by Krichever (see [3]).

Consider a representation of rational maps in pole-residue form for simple poles along with a half (1dToda or dKP) of flows. In the Takasaki gauge [9, 2]

$$z(w) = w + u_0 + \sum_{\alpha=1}^{N} \frac{u_\alpha}{w - w_\alpha}. \tag{13}$$

The new flows attached to the poles are defined as before

$$\partial_{t_{k,\alpha}} z = \{B_{k,\alpha}, z\}, \qquad \alpha = \infty, 1, 2, \ldots, \quad k = 0, 1, 2, \ldots \tag{14}$$

with the evolution operators being associated with the pole structure of z as follows :

$$B_{k,\infty} = \big(z(w)^k\big)_{\geq 0}$$

for an immovable pole at infinity, while for each finite-distance pole there appear additional flows with evolution operators as follows:

$$B_{k,\alpha} = \big(z(w)^k\big)_\alpha, \qquad B_{0,\alpha} = \log(w_\alpha - w).$$

Here, $z(w)_\alpha$ stays for the negative part of a formal expansion of $z(w)$ near its poles w_α:

$$f(w)_\alpha = \sum_{i>0} \frac{f_i}{(w-w_\alpha)^i} \qquad \text{if} \qquad f = \sum_{i \in Z} \frac{f_i}{(w-w_\alpha)^i}. \tag{15}$$

These additional flows commute amongst themselves and with the ordinary (associated with poles at infinity) 1dToda or dKP flows [3].

2.5 Additional invariant flows of the 2dToda system

The dKP hierarchy can be extended to the 2dToda system by introducing an infinite set of $\bar{t}$-flows associated to the poles at $w=0$ and $w=\infty$, similarly the Krichever–Benney system has the following 2dToda extension:

$$z(w)=rw+u_0+\sum_{\alpha=1}^{N}\frac{u_\alpha}{w-w_\alpha},\qquad \bar{z}(1/w)=r/w+\bar{u}_0+\sum_{\beta=1}^{N}\frac{\bar{u}_\beta}{1/w-\bar{w}_\beta}, \tag{16}$$

$$\partial_{t_{k,\alpha}}z=\{H_{k,\alpha},z\},\quad \partial_{\bar{t}_{k,\beta}}\bar{z}=\{\bar{H}_{k,\beta},\bar{z}\},\quad \partial_{t_{k,\alpha}}\bar{z}=\{H_{k,\alpha},\bar{z}\},\quad \partial_{\bar{t}_{k,\beta}}z=\{\bar{H}_{k,\beta},z\}. \tag{17}$$

In (17) we transformed the flows from the Takasaki to the Lax–Sato gauge needed for our purposes. The relation between the evolution operators in different gauges is found to be:

$$H_{k,\alpha}(w)=B_{k,\alpha}(w)-\tfrac{1}{2}B_{k,\alpha}(w=0),\qquad \bar{H}_{k,\beta}(y)=\bar{B}_{k,\beta}(y)-\tfrac{1}{2}\bar{B}_{k,\beta}(y=0), \tag{18}$$

where

$$\begin{aligned}&B_{k,\infty}(w)=(z(w)^k)_{\geq 0},\quad B_{0,\alpha}=\log\left(r(w_\alpha-w)\right),\quad B_{k,\alpha}(w)=(z(w)^k)_\alpha,\\ &\bar{B}_{k,\infty}(y)=(\bar{z}(y)^k)_{\geq 0},\quad \bar{B}_{0,\beta}=\log\left(r(\bar{w}_\beta-y)\right),\quad \bar{B}_{k,\beta}(y)=(\bar{z}(y)^k)_\beta,\quad y=1/w.\end{aligned} \tag{19}$$

Lemma 2. *All vector fields attached to the pole structure of rational maps formally commute, i.e. the introduced evolution operators* (18) *satisfy zero-curvature conditions.*

It is important to note that in the system (17), the equations for the flows $\partial_{t_k}\bar{z}$, $\partial_{\bar{t}_k}z$ do not make a sense fully, since these flows do not preserve the rational ansatz for z, $\bar{z}$ in (13) and (16) until the additional reduction is made. As we have seen before, to be consistent, these systems must be restricted by a string equation, which makes (17) a finite-dimensional dynamical system.

Proposition 3. *The* $4N+2$ *commuting Toda–Krichever flows*

$$\begin{aligned}&\partial_{\tau_i}z=\{h_i,z\},\qquad \partial_{\bar{\tau}_i}z=\left\{\bar{h}_i,z\right\},\\ &\partial_{\tau_i}\bar{z}=\{h_i,\bar{z}\},\qquad \partial_{\bar{\tau}_i}\bar{z}=\left\{\bar{h}_i,\bar{z}\right\},\qquad i=0,\dots,2N,\end{aligned} \tag{20}$$

where

$$\begin{aligned}&h_0=H_{1,\infty}=rw+u_0/2, && \bar{h}_0=\bar{H}_{1,\infty}=r/w+\bar{u}_0/2,\\ &h_{2i-1}=H_{1,i}=\frac{u_i}{w-w_i}+\frac{u_i}{2w_i}, && \bar{h}_{2i-1}=\bar{H}_{1,i}=\frac{\bar{u}_i}{\bar{w}_i-1/w}+\frac{1}{2}\bar{u}_i/\bar{w}_i,\\ &h_{2i}=H_{0,i}=\log(w_i-w)+1/2\log(r/w_i), && \bar{h}_{2i}=\bar{H}_{0,i}=\log(\bar{w}_i-1/w)+1/2\log(r/\bar{w}_i)\end{aligned} \tag{21}$$

and

$$\tau_0=t_{1,\infty},\quad \tau_{2i-1}=t_{1,i},\quad \tau_{2i}=t_{0,i},\quad \bar{\tau}_0=\bar{t}_{1,\infty},\quad \bar{\tau}_{2i-1}=\bar{t}_{1,i},\quad \bar{\tau}_{2i}=\bar{t}_{0,i} \tag{22}$$

preserve the rational form of $z(w)$ (13) *and* $\bar{z}(1/w)$ (16) *(or equally* (10), (9)*) provided the string equation* (6) *holds.*

As in the polynomial case, the total number of invariant flows equals the dimension of the dynamical system minus one. In what follows we show that these flows are Hamiltonian. Since the dimension of the phase space is odd and is equal to $4N+3$, it is, in fact a Poisson manifold where the dimension of the symplectic leaf is $4N+2$. This last number is exactly equal to the number of commuting Toda–Krichever flows.

Now we conjecture that the stated result is true for the more general setting. We introduce a logarithmic ansatz for the 2dToda hierarchy and prove Lemma 2 and Proposition 3 for logarithms followed by a limiting procedure.

2.6 Logarithmic flows

As was mentioned above, it is easier to prove consistency of the rational ansatz with the dynamics of the 2dToda system using the more general Logarithmic solutions. Let us set:

$$z = r(x)w + u(x) + \sum_{i=1}^{n+1} a_i \log(w_i(x) - w), \qquad \sum_{i=1}^{n+1} a_i = 0,$$
$$\bar{z} = r(x)w^{-1} + \bar{u}(x) + \sum_{i=1}^{n+1} \bar{a}_i \log\left(\bar{w}_i(x) - w^{-1}\right), \qquad \sum_{i=1}^{n+1} \bar{a}_i = 0, \qquad i = 1, \dots, n+1, \quad (23)$$

where a_i, $\bar{a}_i$ are arbitrary constants, subject to conditions $\sum\limits_{i=1}^{n+1} a_i = 0$, $\sum\limits_{i=1}^{n+1} \bar{a}_i = 0$ which ensure the absence of logarithmic singularities at infinity. For the introduced ansatz (23) we claim the following result:

Proposition 4. *Let us generalize the evolution operators to be as follows:*

$$\mathcal{H}_0 = r(x)w + \tfrac{1}{2}u(x), \qquad \bar{\mathcal{H}}_0 = \bar{r}(x)w^{-1} + \tfrac{1}{2}\bar{u}(x),$$
$$\mathcal{H}_i = \log(w_i(x) - w) + \tfrac{1}{2}\log(r(x)/w_i(x)),$$
$$\bar{\mathcal{H}}_i = \log\left(\bar{w}_i(x) - w^{-1}\right) + \tfrac{1}{2}\log(r(x)/\bar{w}_i(x)), \qquad i = 1, \dots, n+1. \quad (24)$$

Then, the $2n+4$ flows generated by the Lax equations

$$\partial_{\tau_i} z = \{\mathcal{H}_i, z\}, \qquad \partial_{\bar{\tau}_i} z = \left\{\bar{\mathcal{H}}_i, z\right\},$$
$$\partial_{\tau_i} \bar{z} = \{\mathcal{H}_i, \bar{z}\}, \qquad \partial_{\bar{\tau}_i} \bar{z} = \left\{\bar{\mathcal{H}}_i, \bar{z}\right\}, \qquad i = 0, \dots, n+1 \quad (25)$$

commute. They preserve the logarithmic ansatz (23) *provided the string equation* (6) *holds.*

In other words, the 2dToda flows are tangent to the manifold of logarithmic functions if the string condition is imposed and we again have $2n+4$ flows leaving invariant a $2n+5$ dimensional sub-manifold of the 2dToda system.

It is easier to prove the proposition in the Takasaki gauge. For this purpose we give the transition formulas between different gauges before the proof. For the general 2dToda hierarchy, the Lax functions $z^{(g)}$ and $\bar{z}^{(g)}$ in an arbitrary g-gauge are expressed through the Lax–Sato gauge which corresponds to $g = 0$, $z = z^{(0)}$, $\bar{z} = \bar{z}^{(0)}$ as follows

$$z^{(g)}(w) = z\big(w/r^{2g}\big) = r(x)^{1-2g}w + \sum_{i=-\infty}^{0} u_i^{(g)}(x)w^i,$$
$$\bar{z}^{(g)}\big(w^{-1}\big) = \bar{z}\big(r^{2g}/w\big) = r(x)^{1+2g}w + \sum_{i=0}^{\infty} \bar{u}_i^{(g)}(x)w^i$$

while, (omitting evident subscripts)

$$H^{(g)}(w) = B^{(g)}(w) - \left(\tfrac{1}{2} - g\right) B^{(g)}(w = 0),$$
$$\bar{H}^{(g)}(1/w) = \bar{B}^{(g)}(1/w) - \left(\tfrac{1}{2} + g\right) \bar{B}^{(g)}(1/w = 0). \quad (26)$$

Here, $B^{(g)}$ and $\bar{B}^{(g)}$ are specified similarly to those in (19). In particular, in the Takasaki gauge $g = 1/2$ (below we omit superscripts (1/2))

$$z = w + u(x) + \sum_{i=1}^{n+1} a_i \log(w_i(x) - w),$$

$$\bar z = r(x)^2 w^{-1} + \bar u(x) + \sum_{i=1}^{n+1} \bar a_i \log\left(\bar w_i(x) - w^{-1}\right), \tag{27}$$

$$\mathcal{H}_0 = w + u(x), \qquad \bar{\mathcal{H}}_0 = r(x)^2 w^{-1},$$

$$\mathcal{H}_i = \log(w_i(x) - w), \qquad \bar{\mathcal{H}}_i = \log\left(\bar w_i(x) - w^{-1}\right) + \log(w_i(x)/r(x)). \tag{28}$$

Proof of Proposition 4.

1. *Formal commutativity of flows.* We demonstrate the commutativity of $\partial_{\tau_i} z$, and $\partial_{\tau_j} z$. The proof is similar for the rest of the flows.

The commutativity of the flows is equivalent to the zero-curvature equation

$$\{\mathcal{H}_i, \mathcal{H}_j\} - \frac{\partial \mathcal{H}_j}{\partial \tau_i} + \frac{\partial \mathcal{H}_i}{\partial \tau_j} = 0. \tag{29}$$

Equations (28), (27) and (25) imply that

$$\frac{\partial \mathcal{H}_j}{\partial \tau_i} = \frac{\partial_{\tau_i} w_j}{w_j - w} = \frac{1}{a_j}(\partial_{\tau_i} z)_j = \frac{1}{a_j}\{\mathcal{H}_i, z\}_j,$$

where subscript j stands for the singular part of the expansion around w_j (see (15)). Thus instead of the lhs of (29) we have

$$\{\mathcal{H}_i, \mathcal{H}_j\} - \frac{1}{a_j}\{\mathcal{H}_i, \mathcal{H}_j\}_j + \frac{1}{a_i}\{\mathcal{H}_i, \mathcal{H}_j\}_i$$

which is zero by direct calculation applying (28) and (5). This proves the formal commutativity of the flows.

2. *Consistency of* (27) *with equations of motion* (25). In a way similar to that of the polynomial and rational cases the consistency of the half-flows $\partial_{\tau_i} z$, and $\partial_{\bar\tau_i} \bar z$ for logarithmic solutions is automatic and does not require any extra restrictions on the coefficients (the proof is also similar). In the logarithmic ansatz the main obstacle appears for the flows $\partial_{\tau_i} \bar z$ and $\partial_{\bar\tau_i} z$. We prove the consistency for $\partial_{\bar\tau_i} z$. The proof for $\partial_{\tau_i} \bar z$ is similar.

Differentiating z directly with respect to $\bar\tau_i$ and using the equation of motion (25) we get

$$\partial_{\bar\tau_i} z = \partial_{\bar\tau_i} u + \sum_{j=1}^{n+1} \frac{a_i \partial_{\bar\tau_i} w_j}{w - w_j} = \{\bar{\mathcal{H}}_i, z\}.$$

The lhs of the equation contains only singularities of z. Using definition (5) and equations (27), (28), we see that the rhs contains both singularities of z and one singularity of $\bar{\mathcal{H}}_i$. In order for the equation of motion to be consistent with the logarithmic ansatz, the rhs, $\{\bar{\mathcal{H}}_i, z\}$, must contain the same singularities as those in the lhs, i.e. it must not contain a singularity of $\bar{\mathcal{H}}_i$ at $w = 1/\bar w_i$.

Let us exploit the fact that in the Takasaki gauge (27), (28), z and $\bar z$ can be represented as sums over the corresponding $\mathcal{H}$:

$$z = \mathcal{H}_0 + \sum_{i=1}^{n+1} a_i \mathcal{H}_i, \qquad \bar z = \bar{\mathcal{H}}_0 + \sum_{i=1}^{n+1} \bar a_i \bar{\mathcal{H}}_i + f(r, w_1, \dots, w_{n+1}), \tag{30}$$

where f is a w-independent function. Note that the conditions $\sum\limits_{i=1}^{n+1} a_i = 0$, $\sum\limits_{i=1}^{n+1} \bar a_i = 0$ of Proposition 4 ensure that there are no logarithmic singularities at infinity.

Now, using (30) we obtain the following expression

$$\bar{a}_i\{\bar{\mathcal{H}}_i, z\} = \Big\{\bar{z} - f - \sum_{j\neq i} \bar{a}_j\bar{\mathcal{H}}_j, z\Big\} = \{\bar{z}, z\} - \{f, z\} - \sum_{j\neq i} \bar{a}_j\{\bar{\mathcal{H}}_j, z\}.$$

The term $\sum\limits_{j\neq i} \bar{a}_j\{\bar{\mathcal{H}}_j, z\}$ of the rhs of the last expression does not contain singularities of $\bar{H}_i$ since it does not contain the index i in the sum. The next term $\{f, z\}$ does not contain them either, since f is independent of w. The only term which may contain undesired singularities is $\{\bar{z}, z\}$, however the string equation (6) holds and therefore $\{\bar{\mathcal{H}}_i, z\}$ is free of singularities of $\bar{z}$. Thus the equation of motion is consistent with the logarithmic ansatz due to the string equation. ■

Corollary 1. *The consistency of the rational ansatz follows from the consistency of the logarithmic ansatz. (Proposition 3 is a consequence of Proposition 4).*

Proof. Choosing $n = 2N - 1$ and substituting the values

$$\begin{aligned} &a_{2i-1} = 1/\epsilon, \qquad a_{2i} = -1/\epsilon, \qquad w_{2i} = w_{2i-1} + \epsilon u_i, \\ &\bar{a}_{2i-1} = 1/\epsilon, \qquad \bar{a}_{2i} = -1/\epsilon, \qquad \bar{w}_{2i} = \bar{w}_{2i-1} + \epsilon \bar{u}_i \end{aligned} \tag{31}$$

for z and $\bar{z}$ into (23) we get rational solutions (16), (13) in the $\epsilon \to 0$ limit.

The Hamiltonians are then related as follows:

$$\begin{aligned} &h_0 = \lim_{\epsilon=0} \mathcal{H}_0, && \bar{h}_0 = \lim_{\epsilon=0} \bar{\mathcal{H}}_0, \\ &h_{2i-1} = \lim_{\epsilon=0} \frac{1}{\epsilon}(\mathcal{H}_{2i} - \mathcal{H}_{2i-1}), && \bar{h}_{2i} = \lim_{\epsilon=0} \frac{1}{\epsilon}(\bar{\mathcal{H}}_{2i} - \bar{\mathcal{H}}_{2i-1}), \\ &h_{2i} = \lim_{\epsilon=0} \mathcal{H}_{2i-1}, && \bar{h}_{2i-1} = \lim_{\epsilon=0} \bar{\mathcal{H}}_{2i-1}. \end{aligned}$$ ■

Thus we have obtained a rational ansatz as a limiting case of the logarithmic ansatz, merging pairs of logarithmic singularities together, in which case they become simple poles. In a similar way one may deduce any kind of rational maps containing a combination of poles of any degrees absorbing different numbers of logarithmic singularities.

The paper concerns the Hamiltonian structure of the finite-dimensional reductions 2D dispersionless Toda hierarchy constrained by the string equation. We derive the Hamiltonian structure of the reduced dynamics and show connections of integrals of "multi-finger" solutions of the Laplacian growth problem with the "Toda–Krichever" flows of the 2dToda hierarchy constrained by a string equation. The Poisson structure of the rationally reduced 1dToda hierarchy is also derived.

1 Hamiltonians and action-angle variables

In this paper we study the Poisson structure of rational reductions of the 2dToda hierarchy, introduced in the previous paper of the present volume [1]. These reductions, as seen from the above considerations, form a finite-dimensional completely integrable system. We find explicit expressions leading to a canonical Hamiltonian structure on the phase space of rational reductions of the 2D dToda system. Such reductions are interesting from the point of view of the applications mentioned in the Introduction.

A reader interested in the Poisson structure of rational reductions of the 1dToda hierarchy (which are infinite-dimensional, unrestricted by string equation systems) will find it in the second part of the paper. This structure, which turns out to be a quadratic algebra, is interesting by itself.

Since the Toda flows commute, the Toda times are actually the action-angle variables of the system.

Thus we have only to express the times through coordinates of the phase space. For the logarithmic ansatz [1, Proposition 4] the following result holds[1]:

Proposition 1. *The times τ_i, $\bar\tau_i$ of equation* ([1].25) *are expressed in terms of z and $\bar z$* ([1].23) *as*

$$\tau_0 = \frac{1}{2\pi\sqrt{-1}}\oint_\infty \bar z d\ln z + \text{const}, \qquad \bar\tau_0 = \frac{1}{2\pi\sqrt{-1}}\oint_0 z d\ln\bar z + \text{const},$$
$$\tau_i = \frac{1}{2\pi\sqrt{-1}}\oint_{w_i} \bar z dz + \text{const}, \qquad \bar\tau_i = \frac{1}{2\pi\sqrt{-1}}\oint_{1/\bar w_i} z d\bar z + \text{const}, \qquad i = 1,\dots,n+1$$

or, in other words, the following values

$$I_0 = \bar z(1/w=0) = \bar u + \sum_{i=1}^{n+1}\bar a_i \ln(\bar w_i), \qquad \bar I_0 = z(0) = u + \sum_{i=1}^{n+1} a_i \ln(w_i),$$

[1]Here and below equations from [1] are cited in the form ([1].N), where N is the number of corresponding equation.

$$I_i = a_i \bar{z}(w_i^{-1}) = a_i \left(r w_i^{-1} + \bar{u} + \sum_{j=1}^{n+1} \bar{a}_j \ln(\bar{w}_j - w_i^{-1}) \right),$$
$$\bar{I}_i = \bar{a}_i z(\bar{w}_i^{-1}) = \bar{a}_i \left(r \bar{w}_i^{-1} + u + \sum_{j=1}^{n+1} a_j \ln(w_j - \bar{w}_i^{-1}) \right), \qquad i = 1, \dots, n+1, \tag{1}$$

are the action-angle variables and

$$\begin{aligned} Q &= \frac{1}{4\pi\sqrt{-1}} \sum_{i=0}^{n+1} \oint_{1/\bar{w}_i} z d\bar{z} + \oint_{w_i} \bar{z} dz \\ &= \frac{1}{2} r \left(\left(\frac{\partial z(w)}{\partial w} \right)_{w=0} + \left(\frac{\partial \bar{z}(1/w)}{\partial (1/w)} \right)_{1/w=0} \right) - \frac{1}{2} \sum_{i=1}^{n+1} \left(I_i + \bar{I}_i \right) \\ &= r^2 - \frac{1}{2} \sum_{i=1}^{n+1} \left(r \left(\frac{a_i}{w_i} + \frac{\bar{a}_i}{\bar{w}_i} \right) + I_i + \bar{I}_i \right) \end{aligned} \tag{2}$$

is a Casimir for ([1].25).

Proof. We first calculate the derivatives of each I_i with respect to the times τ_i, $\bar{\tau}_i$, $i = 1, \dots, n$. Using integration by parts, we get

$$2\pi\sqrt{-1} \frac{\partial I_i}{\partial \tau_j} = \frac{\partial}{\partial \tau_j} \oint_{w_i} \bar{z} \frac{\partial z}{\partial w} dw = \oint_{w_i} \frac{\partial}{\partial w} \left(\bar{z} \frac{\partial z}{\partial \tau_j} \right) dw + \oint_{w_i} \left(\frac{\partial \bar{z}}{\partial \tau_j} \frac{\partial z}{\partial w} - \frac{\partial z}{\partial \tau_j} \frac{\partial \bar{z}}{\partial w} \right) dw.$$

By equations of motion ([1].25), definition of the Lax–Poisson brackets ([1].5) and by the string equation ([1].6) this value reduces to:

$$\begin{aligned} &\oint_{w_i} \frac{\partial}{\partial w} \left(\bar{z} \frac{\partial z}{\partial \tau_j} \right) dw + \oint_{w_i} \left(\{\mathcal{H}_j, \bar{z}\} \frac{\partial z}{\partial w} - \{\mathcal{H}_j, z\} \frac{\partial \bar{z}}{\partial w} \right) dw \\ &\quad = \oint_{w_i} \frac{\partial}{\partial w} \left(\bar{z} \frac{\partial z}{\partial \tau_j} \right) dw + \oint_{w_i} \frac{\partial \mathcal{H}_j}{\partial w} w \left(\frac{\partial z}{\partial w} \frac{\partial \bar{z}}{\partial x} - \frac{\partial z}{\partial x} \frac{\partial \bar{z}}{\partial w} \right) dw \\ &\quad = \oint_{w_i} \frac{\partial}{\partial w} \left(\bar{z} \frac{\partial z}{\partial \tau_j} \right) dw + \oint_{w_i} \frac{\partial \mathcal{H}_j}{\partial w} dw = 2\pi\sqrt{-1} \delta_{ij}. \end{aligned}$$

We get the Kronecker δ-symbol as the final answer, since the first term in the last line vanishes. Indeed, this occurs because $\bar{z} \frac{\partial z}{\partial \tau_j}$ is a meromorphic in w in the vicinity of any singularity w_i of z and the second term gives the δ_{ij} contribution by definition ([1].24) of $\mathcal{H}_j$.

Using similar reasoning we prove the rest of the proposition. ■

The values (1) are similar to those appearing in the work [8] in connection with the Laplacian Growth problem as integrals of the Laplacian Growth (string) equation. The following proposition (although not assuming complex structure) confirms this fact.

Proposition 2. *The values* (1) *form a set of integrals of the string equation* ([1].6)*, i.e., provided the string equation holds.*

$$dI_i/dx = 0$$

while for the Casimir (2) *we have*

$$dQ/dx = 1.$$

Proof. This is similar to the proof of proposition (1); one has to take the same steps substituting x for τ_i. ■

As was mentioned in the Introduction the Laplacian growth problem is endowed with a complex structure, with $\bar{z}$ being the complex conjugate of z (and bar denoting complex conjugation). Then, as may be seen from the proposition, the Casimir Q plays the role of the area (which grows with the unit speed), while I are functions of the harmonic moments of the boundary curve.

Since the equations of motion ([1].25) have the following form in I, $\bar{I}$

$$\begin{aligned} &\partial_{\tau_j} Q = 0, \qquad \partial_{\bar{\tau}_j} Q = 0, \qquad \partial_{\tau_j} I_i = \delta_{ij}, \\ &\partial_{\bar{\tau}_j} I_i = 0, \qquad \partial_{\tau_j} \bar{I}_i = 0, \qquad \partial_{\bar{\tau}_j} \bar{I}_i = -\delta_{ij} \end{aligned} \tag{3}$$

these variables are canonical. For instance, we may choose the following Poisson structure

$$\{I_i, \bar{I}_j\}_p = \delta_{ij}, \qquad \{I_i, I_j\}_p = \{\bar{I}_i, \bar{I}_j\}_p = 0, \qquad \{Q, \bar{I}_j\}_p = \{Q, I_j\}_p = 0, \tag{4}$$

$$\mathrm{H}_i = \bar{I}_i, \qquad \bar{\mathrm{H}}_i = I_i. \tag{5}$$

It is important to note that the Poisson brackets $\{\ ,\ \}_p$ in (4) are different from $\{\ ,\ \}$ in ([1].5): The former defines the Poisson structure on the space of rational solutions of the 2dToda hierarchy, while the latter (Lax–Poisson bracket) is a dispersionless limit of the commutator.

To get similar results for the rational case we have to take a limit as in Corollary 1 of [1].

Corollary 1. *Let z, $\bar{z}$ be represented as in* ([1].13)–([1].16). *The following $2N+1$ values $(i = 1, \dots, N)$*

$$I_0 = \bar{u}_0 - \sum_{i=1}^{N} \bar{u}_i/\bar{w}_i, \qquad \bar{I}_0 = u_0 - \sum_{i=1}^{N} u_i/w_i,$$

$$I_{2i-1} = r w_i^{-1} + \bar{u}_0 + \sum_{j=1}^{N} \frac{\bar{u}_j}{1/w_i - \bar{w}_j}, \qquad \bar{I}_{2i-1} = r \bar{w}_i^{-1} + u_0 + \sum_{j=1}^{N} \frac{u_j}{1/\bar{w}_i - w_j},$$

$$I_{2i} = \left(r - \sum_{j=1}^{N} \frac{\bar{u}_j}{(1/w_i - \bar{w}_j)^2} \right) \frac{u_i}{w_i^2}, \qquad \bar{I}_{2i} = \left(r - \sum_{j=1}^{N} \frac{u_j}{(1/\bar{w}_i - w_j)^2} \right) \frac{\bar{u}_i}{\bar{w}_i^2}$$

$$Q = r^2 - \frac{1}{2} \sum_{i=1}^{N} \left(r \left(\frac{\bar{u}_i}{\bar{w}_i^2} + \frac{u_i}{w_i^2} \right) + \bar{I}_{2i} + I_{2i} \right)$$

are the action-angle variables in the rational case [1, Proposition 3], i.e. the variables for which equations in this Proposition have the form (3).

Again, in the rational limit we may choose the Poisson structure as in (4), (5).

2 Poisson structure of the 1dToda hierarchy

In this section we consider the Poisson structure of rational reductions of the 1dToda system.

Recall, that for the 1dToda system one takes into account only a "half" of flows, connected with z (but not $\bar{z}$, or vice verse).

$$\partial_{t_i} z = \{H_i, z\}, \qquad H_i = \big(z(w)^i\big)_+ + \tfrac{1}{2}\big(z(w)^i\big)_0, \qquad i = 0, \dots, \infty. \tag{6}$$

This system is bi-Hamiltonian (for general information e.g. see [3]) with two (linear and quadratic) compatible Poisson structures. As it was first found in [2] for the generic Toda system ([1].2),

the dispersionless linear Poisson brackets for the "field variables" u_i, $i = 1, \ldots, \infty$ have the following form

$$\{u_n(x), u_m(y)\}_1 = 2(c_n + c_m - 1)\big[(n+m)u_{n+m}(x)\delta'(x-y) + mu'_{n+m}(x)\delta(x-y)\big], \tag{7}$$

where

$$c_k = \begin{cases} 1, & \text{if } k > 0, \\ \frac{1}{2}, & \text{if } k = 0, \\ 0, & \text{if } k < 0 \end{cases}$$

while the quadratic brackets are

$$\begin{aligned}\{u_n(x), u_m(y)\}_2 = &\left[\frac{1}{2}(n-m)u_n(x)u'_m(x) + \left(\sum_{k=1}^{1-n}(n-m+k)u_{n+k}(x)u'_{m-k}(x)\right.\right. \\ &\left.\left. + ku'_{n+k}(x)u_{m-k}(x)\right)\right]\delta(x-y) \\ &+ \left[\frac{1}{2}(n-m)u_nu_m + \sum_{k-1}^{1-n}(n-m+2k)u_{n+k}u_{m-k}\right]\delta(x-y). \end{aligned}\tag{8}$$

As seen from the Lemma 1 of [1], the rational functions

$$z(w) = \frac{q_{N+1}(w)}{p_N(w)} = \frac{w^{N+1} + \sum\limits_{i=0}^{N} a_i w^i}{\sum\limits_{i=0}^{N} b_i w^i} \tag{9}$$

are form-invariant under all of the 1dToda flows ∂_{t_i} (6), without any extra restriction (i.e. the string equation is not needed).

We obtain the corresponding Poisson structures for coefficients a_i, b_i, by using result (8), expressing u_i in terms of a_i, b_i, $i = 0, \ldots, N$. Both the linear (7) and quadratic (8) Poisson structures lead to the quadratic brackets for a_i, b_i. Namely, the second Poisson structure for (9) reads as follows

$$\begin{aligned}\{a_k(x), a_l(y)\}_2 = &\left[\sum_{n=1}(l+n-k)a_{k-n}(x)a_{l+n}(y) + na_{k-n}(y)a_{l+n}(x))\right. \\ &\left. + (l-N-1)a_k(x)a_l(y)\right]\delta'(x-y), \end{aligned}\tag{10}$$

$$\begin{aligned}\{b_k(x), b_l(y)\}_2 = &\left[\sum_{n=1}(k-l-n)b_{k-n}(x)b_{l+n}(y) - nb_{k-n}(y)b_{l+n}(x))\right. \\ &\left. + \frac{k-l}{2}b_k(x)b_l(y)\right]\delta'(x-y), \end{aligned}\tag{11}$$

$$\{a_k(x), b_l(y)\}_2 = \frac{k-N-1}{2}a_k(x)b_l(y)\delta'(x-y). \tag{12}$$

The first Poisson structure can be obtained from (10)–(12) with the help of the linear transformation (shift by a constant)

$$a_i \to a_i + \lambda b_i, \qquad z(w,x) \to z(w,x) + \lambda$$

and using the bi-Hamiltonian nature of (7), (8).

$$\{a_k(x), a_l(y)\}_1 = \Bigg[\sum_{n=1}\Big((k-l-n)(a_{k-n}(x)b_{l+n}(y)+b_{k-n}(x)a_{l+n}(y)) - n(a_{k-n}(y)b_{l+n}(x)+b_{k-n}(y)a_{l+n}(x))\Big) + \frac{N+1-l}{2}b_k(x)a_l(y) + \frac{k+N+1-2l}{2}a_k(x)b_l(y)\Bigg]\delta'(x-y), \tag{13}$$

$$\{a_k(x), b_l(y)\}_1 = \Bigg[\sum_{n=1}\Big((k-l-n)b_{k-n}(x)b_{l+n}(y) - nb_{k-n}(y)b_{l+n}(x)\Big) + \frac{N+1-l}{2}b_k(x)b_l(y)\Bigg]\delta'(x-y), \tag{14}$$

$$\{b_k(x), b_l(y)\}_1 = 0 \tag{15}$$

in all the above expressions $a_{N+1} = 1$ and $a_i = 0$ if i goes beyond the range $i = 0, \ldots, N+1$ (and $b_j = 0$ if $j \neq 0, \ldots, N$).

These brackets form a bi-Hamiltonian structure for rational reductions of the 1dToda hierarchy:

$$\partial_{t_i} z = \{\mathrm{H}_i, z\}_1 = \{\mathrm{H}_{i-1}, z\}_2 \tag{16}$$

with the following Hamiltonians:

$$\mathrm{H}_i = \frac{1}{i+1}\int (z^{i+1}(x))_0 dx. \tag{17}$$

3 Summary and perspectives

We have established the Hamiltonian structure on the space of rational solutions of the 2dToda hierarchy connected with the problem of ideal interface dynamics. A further application of this result can become quite challenging in dealing with the problem of encountering a surface tension for the Laplacian growth process.

The Laplacian growth equation ([1].1), ([1].6) describes the propagation of the boundary with zero surface tension between the fields. Although, addressing a number of important questions (e.g. finger width selection problem in [7]), such an idealized model does not account for essential physical features, such as fractal formation, stability etc. Thus, the inclusion of tension effects is important for the solution of the problem.

There are two approaches to look for in such a generalization. The first one is to introduce tension terms in the theory, destroying the integrability of the problem. In another approach one might look for integrable deformations of the idealized model, simulating surface effects and stabilizing interface dynamics.

Another feature that gives our result a certain interest lies in the possible investigation of the perturbed (by small surface tension) system given in terms of separated variables (4). In other words, is it possible, in some situations, to approximate the perturbed solution by the multi-finger ansatz ([1].23) with different dependence of coordinates on time x? If the answer is affirmative we will get a finite-dimensional dynamical system, conveniently written in terms of I, $\bar{I}$, Q.

Finally, returning to the idealized problem, one can further elaborate the theory of rational reductions from the point of view of symmetries. An important observation of our study is

that once a rational reduction is compatible with 2dToda dynamics, the string condition is satisfied automatically. In other words *the string (Laplacian growth) equation* ([1].6) *turns out to be a consequence of rationality* in the context of the 2dToda hierarchy. On the other hand, it is well known that the string equation is connected with additional (Orlov–Schulman [3, 9]) symmetries of the 2dToda hierarchy [10]. It would be interesting to see how the string constraint can be an element of a set of the symmetry constraints leading to the rationality of solutions.

Amongst the other open questions and future directions is the following problem: to investigate Hamiltonian structure of rational reductions in the context of the two-matrix [4] model, whose partition function is a tau-function of the 2dToda system constrained by the string equation. The applicability of our study to the models of normal matrices is another interesting aspect worthy of further analysis [6].

A Conservative Numerical Integration Algorithm for Integrable Henon–Heiles System

Yukitaka MINESAKI and Yoshimasa NAKAMURA

Department of Applied Mathematics and Physics, Graduate School of Informatics, Kyoto University, Kyoto 606-8501, Japan
E-mail: *minesaki@amp.i.kyoto-u.ac.jp, ynaka@i.kyoto-u.ac.jp*

A new conservative numerical integration algorithm for the integrable Henon–Heiles system is presented which conserves *all* of the constants of motion.

1 Introduction

The Henon–Heiles system in celestial mechanics is a well-known chaotic Hamiltonian system [4]. Since this two dimensional system has only one constant of motion, it is a non-integrable system. By simple changes of the Hamiltonian we obtain some completely integrable Henon–Heiles type systems. They are completely integrable in the sense of Liouville–Arnold. Namely, they are two-dimensional systems having two constants of motion cf. [8]. To solve numerically the equations of motion, one often tries to discretize them. Even for the integrable cases a good numerical integration scheme will be useful for describing orbits for arbitrary given initial data.

The symplectic integrators [3, 9] and the energy preserving methods [2, 1] are well-known as good numerical integration schemes. The symplectic integrators conserve the symplectic form in the phase space, so that the resulting discrete-time evolution is regarded as a canonical transformation. Though the symplectic integrators do not conserve Hamiltonian and other additional constants of motion, for example, the angular momentum and the Runge–Lenz vector for the Kepler motion, in general, they are widely used in numerical simulation for the solar system. This is because the symplectic integrators give a good approximation of the orbits of the Hamiltonian system in the sense in which they conserve a modified (or approximate) Hamiltonian. However, a non-existence theorem of modified constant of motion besides the modified Hamiltonian is proved recently in [10,11]. The energy preserving methods originated by Greenspan [2] keep the value of the Hamiltonian constant. These methods are based on discrete variational derivatives [1, 5]. Generally, they conserve only energy and do not preserve other additional constants of motion. It has not been known for long time how to design an energy preserving method which conserves all of the additional constants of motion of certain class of integrable Hamiltonian systems. Especially, it is impossible to trace an ellipse of the Kepler motion, since the Runge–Lentz vector is not conserved by any known numerical integrators including the symplectic integrators and the usual energy preserving methods.

In the previous paper [6] the authors have established a new numerical integration algorithm which conserves all of the constants of motion of the two-dimensional Kepler motion including the Runge–Lenz vector. In this paper we consider one of the integrable Henon–Heiles type systems discussed in [8]. We discretize the Henon–Heiles system which preserves all constants of motion as an application of the numerical integration algorithm.

It is also shown in this paper that 1) a time step size, which is larger than those of other known integrators, is easily used, 2) a variable time step is naturally introduced. These basic properties underlie the efficiency of the new numerical integration algorithm.

2 Integrable Henon–Heiles system and canonical transformation

The integrable Henon–Heiles system is defined by the Hamiltonian

$$\mathcal{H}_{\mathrm{hh}-1}(p_x, p_y, x, y) = p_x^2 + p_y^2 + x^2 + y^2 + \frac{2}{3}x^3 + 2xy^2 - E_{\mathrm{hh}} \tag{1}$$

on a subset of $\mathbf{R}^4 = \{p_x, p_y, x, y\}$, where E_{hh} is an arbitrary constant. The time variable is t. When the positive sign of $\frac{2}{3}x^3$ in (1) becomes changed to negative, (1) is the Hamiltonian of a chaotic dynamical system in celestial mechanics [4]. The equation of motion for (1) are expressed with

$$\frac{dx}{dt} = 2p_x, \qquad \frac{dy}{dt} = 2p_y, \qquad \frac{dp_x}{dt} = -2x^2 - 2x - 2y^2, \qquad \frac{dp_y}{dt} = -4xy - 2y. \tag{2}$$

After a canonical transformation

$$q_1 = \frac{1}{2}(x + y), \qquad q_2 = \frac{1}{2}(x - y), \qquad p_1 = p_x + p_y, \qquad p_2 = p_x - p_y, \tag{3}$$

the Hamiltonian (1) leads to the Hamiltonian

$$\mathcal{H}_{\mathrm{hh}-2}(p_1, p_2, q_1, q_2) = \frac{1}{2}\left(p_1^2 + p_2^2 + U(q_1) + U(q_2)\right) \tag{4}$$

on a subset of $\mathbf{R}^4 = \{p_1, p_2, q_1, q_2\}$, where the potential functions are

$$U(q_j) = \frac{16}{3}q_j^3 + 4q_j^2 - E_{j,\mathrm{hh}}, \qquad j = 1, 2. \tag{5}$$

The variables p_k and q_k are now separated. Note that the canonical transformation (3) is a mapping from $\mathbf{R}^4$ to $\mathbf{R}^4$. The equations of motion are then

$$\frac{dq_k}{dt} = p_k, \qquad \frac{dp_k}{dt} = -8q_k^2 - 4q_k, \qquad k = 1, 2. \tag{6}$$

They are just the equations of the two-dimensional anharmonic oscillator with the Hamiltonian (4) on $\mathbf{R}^4 = \{p_1, p_2, q_1, q_2\}$ with the time t. Let us set the constant E_{hh} in $\mathcal{H}_{\mathrm{hh}-2}$ such that

$$\mathcal{H}_{\mathrm{hh}-2}(p_1, p_2, q_1, q_2) = 0. \tag{7}$$

Obviously, $\mathcal{H}_{\mathrm{hh}-1}(p_x, p_y, x, y) = 0$ for such E_{hh}. Since $\mathcal{H}_{\mathrm{hh}-2}$ is a constant of motion of (6), the value of the constant E_{hh} reflects the initial values of the variables p_k and q_k. Namely, E_{hh} is expressed as

$$E_{\mathrm{hh}} = E_{1,\mathrm{hh}} + E_{2,\mathrm{hh}}, \tag{8}$$

where

$$E_{j,\mathrm{hh}} = \frac{1}{2}\left(p_j(0)^2 + U(q_j(0))\right), \qquad j = 1, 2. \tag{9}$$

We see that the canonical transformation (3) generates a transformation that maps the integrable Henon–Heiles system to a system of anharmonic oscillators.

The integrable Henon–Heiles system has an additional constant of motion. This constant is the angular momentum

$$I_{2,\mathrm{hh}-1}(p_x, p_y, x, y) = 2p_xp_y + 4x^2y + \frac{4}{3}y^3 + 4xy - E_{1,\mathrm{hh}} + E_{2,\mathrm{hh}}. \tag{10}$$

The constants of motion are expressed by using the canonical variables p_k and q_k as follows. The Hamiltonian $\mathcal{H}_{\mathrm{hh}-2}(p_k, q_k)$ is as (4), where $(p_k, q_k) = (p_1, p_2, q_1, q_2)$, for simplicity. Note that (10) is expressed as

$$I_{2,\mathrm{hh}-2} = \frac{1}{2}\left(p_1^2 - p_2^2\right) + \frac{8}{3}\left(q_1^3 - q_2^3\right) + 2\left(q_1^2 - q_2^2\right). \tag{11}$$

3 Discrete integrable Henon–Heiles system

The equations of motion of the two-dimensional oscillator (6) are discretized by the energy preserving method (cf. [2,5]) as follows,

$$\begin{aligned}
&\frac{Q_k^{(j+1)}-Q_k^{(j)}}{t^{(j+1)}-t^{(j)}}=\frac{P_k^{(j)}+P_k^{(j+1)}}{2},\\
&\frac{P_k^{(j+1)}-P_k^{(j)}}{t^{(j+1)}-t^{(j)}}=-\frac{8\left(\left(Q_k^{(j+1)}\right)^2+Q_k^{(j+1)}Q_k^{(j)}+\left(Q_k^{(j)}\right)^2\right)+6\left(Q_k^{(j+1)}+Q_k^{(j)}\right)}{3},\\
&t^{(0)}<\cdots<t^{(j-1)}<t^{(j)}<t^{(j+1)}<\cdots,
\end{aligned}\tag{12}$$

where $t^{(j)}$ is an arbitrarily increasing sequence which indicates a discrete-time, $P_k^{(j)}$, $Q_k^{(j)}$ are the values of the variables P_k, Q_k at the time $t^{(j)}$, respectively. Here P_k and Q_k are discrete analogues of the canonical variables p_k and q_k, respectively, where we set

$$P_k^{(0)}=p_k(0),\qquad Q_k^{(0)}=q_k(0),\qquad k=1,2.\tag{13}$$

On the orbit of the two-dimensional discrete-time harmonic oscillator (12) the Hamiltonian (4) is kept constant for any $t^{(j)}$, namely,

$$\mathcal{H}_{\mathrm{hh}-2}\big(P_k^{(j+1)},Q_k^{(j+1)}\big)=\mathcal{H}_{\mathrm{hh}-2}\big(P_k^{(j)},Q_k^{(j)}\big),\qquad j=0,1,\ldots,\tag{14}$$

where $\big(P_k^{(j)},Q_k^{(j)}\big)=\big(P_1^{(j)},P_2^{(j)},Q_1^{(j)},Q_2^{(j)}\big)$. This is a direct consequence of the energy preserving method. Since $\mathcal{H}_{\mathrm{hh}-2}(p_k,q_k)=0$, $P_k^{(0)}=p_k(0)$ and $Q_k^{(0)}=q_k(0)$, we obtain

$$\begin{aligned}
&\mathcal{H}_{\mathrm{hh}-2}\big(P_k^{(j)},Q_k^{(j)}\big)=0,\quad j=0,1,\cdots,\\
&E_{k,\mathrm{hh}}=\frac{1}{2}\big(P_k^{(0)}\big)^2+\frac{8}{3}\big(Q_k^{(0)}\big)^3+2\big(Q_k^{(0)}\big)^2,\qquad k=1,2.
\end{aligned}\tag{15}$$

Through the inverse of the canonical transformation (3) the discrete-time system (12) is converted to

$$\begin{aligned}
&\frac{X^{(j+1)}-X^{(j)}}{t^{(j+1)}-t^{(j)}}=P_X^{(j+1)}+P_X^{(j)},\qquad \frac{Y^{(j+1)}-Y^{(j)}}{t^{(j+1)}-t^{(j)}}=P_Y^{(j+1)}+P_Y^{(j)},\\
&\frac{P_X^{(j+1)}-P_X^{(j)}}{t^{(j+1)}-t^{(j)}}=-\frac{2}{3}\Big(\Big(\big(X^{(j+1)}\big)^2+X^{(j+1)}X^{(j)}+\big(X^{(j)}\big)^2\Big)\\
&\qquad\qquad+\Big(\big(Y^{(j+1)}\big)^2+Y^{(j+1)}Y^{(j)}+\big(Y^{(j)}\big)^2\Big)\Big)-\big(X^{(j+1)}+X^{(j)}\big),\\
&\frac{P_Y^{(j+1)}-P_Y^{(j)}}{t^{(j+1)}-t^{(j)}}=-\frac{2}{3}\Big(2X^{(j+1)}Y^{(j+1)}+2X^{(j)}Y^{(j)}\\
&\qquad\qquad+X^{(j+1)}Y^{(j)}+X^{(j)}Y^{(j+1)}\Big)-\big(Y^{(j+1)}+Y^{(j)}\big).
\end{aligned}\tag{16}$$

Equations (16) preserve the value of $\mathcal{H}_{\mathrm{hh}-1}\big(P_X^{(j)},P_Y^{(j)},X_1^{(j)},Y^{(j)}\big)$ as zero. We call (16) the *discrete integrable Henon–Heiles system*.

4 Discrete integrable Henon–Heiles system as exactly conservative integrator

In the previous section the Hamiltonian $\mathcal{H}_{\mathrm{hh}-1}(P_X^{(j)},P_Y^{(j)},X^{(j)},Y^{(j)})$ is shown to be constant under the time evolution of the discrete integrable Henon–Heiles system (16). The other constant

of motion (10) of the continuous-time integrable Henon–Heiles is also conserved. Now we are in a position to state the main result.

Theorem 1. *The integrable Henon–Heiles system* (16) *has the following two constants of motion. The first is the Hamiltonian*

$$\mathcal{H}_{\mathrm{d-hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big) = \mathcal{H}_{\mathrm{hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big). \tag{17}$$

The second constant is a discrete analogue of the angular momentum (10)

$$\begin{aligned} &I_{2,\mathrm{d-hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big) \\ &\quad = 2P_X^{(j)}P_Y^{(j)} + 4\big(X^{(j)}\big)^2 Y^{(j)} + \frac{4}{3}\big(Y^{(j)}\big)^3 + 4X^{(j)}Y^{(j)} - E_{1,\mathrm{hh}} + E_{2,\mathrm{hh}}. \end{aligned} \tag{18}$$

The proof follows by a direct calculation with an alternative expression of the discrete integrable Henon–Heiles system (16). We here give an important remark.

Remark 1. The form of the constants (17) and (18) of motion is consistent with that of the continuous-time integrable Henon–Heiles system. Namely,

$$\begin{aligned} &\mathcal{H}_{\mathrm{d-hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big) = \mathcal{H}_{\mathrm{hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big), \\ &I_{2,\mathrm{d-hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big) = I_{2,\mathrm{hh-1}}\big(P_X^{(j)}, P_Y^{(j)}, X^{(j)}, Y^{(j)}\big). \end{aligned} \tag{19}$$

Finally in this section we give a numerical example for the discrete integrable Henon–Heiles system. Fig. 1[1] indicates the orbits of the symplectic Euler scheme with step-size $t^{(j+1)} - t^{(j)} = dt = 0.1,\ 0.2,\ 0.4$, the initial value is $X^{(0)} = 0.0$, $Y^{(0)} = 0.0$, $P_X^{(0)} = 0.35$, $P_Y^{(0)} = -0.15$. Especially, the orbit with step-size $t^{(j+1)} - t^{(j)} = dt = 0.4$ is quite different from that of the continuous-time integrable Henon–Heiles system. In contract to the orbits given by the symplectic Euler scheme, the discrete integrable Henon–Heiles system with the constant discrete step-size $t^{(j+1)} - t^{(j)} = \delta = 0.1,\ 0.2,\ 0.4$ draws orbits which give a better approximation than those of the symplectic Euler scheme in Fig. 2. Moreover, the discrete integrable Henon–Heiles system with variable step-size gives the almost same orbit as the continuous-time integrable Henon–Heiles system has. Fig. 3 displays the orbit of the discrete integrable Henon–Heiles system with a step-size changing periodically from 0.1 to 0.2.

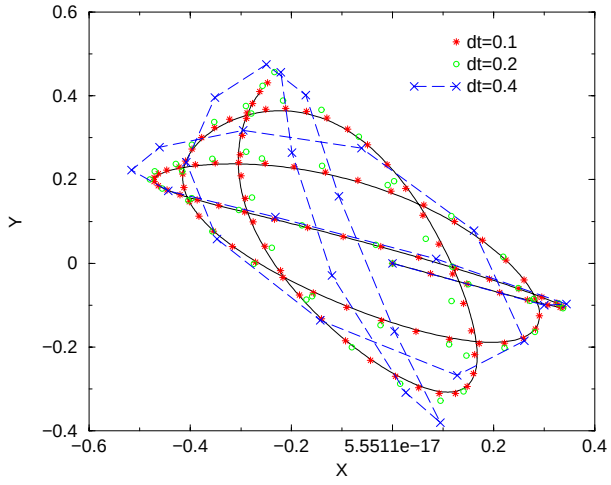

Figure 1. Symplectic Euler scheme $\delta = 0.1,\ 0.2,\ 0.4$.

[1]Figures in colour will be available only in electronic version.

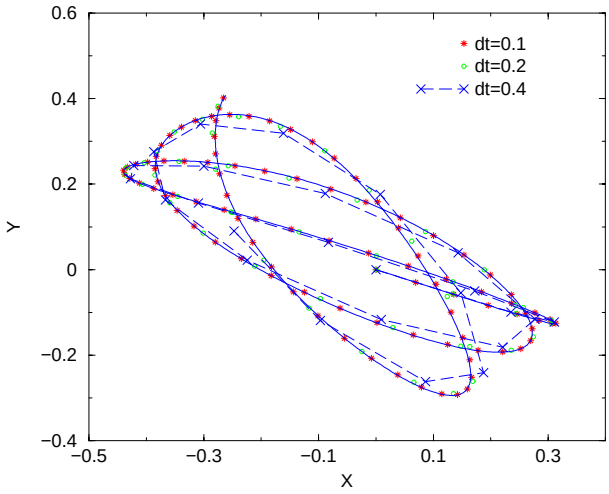

Figure 2. Discrete integrable Henon–Heiles $\delta = 0.1,\ 0.2,\ 0.4$.

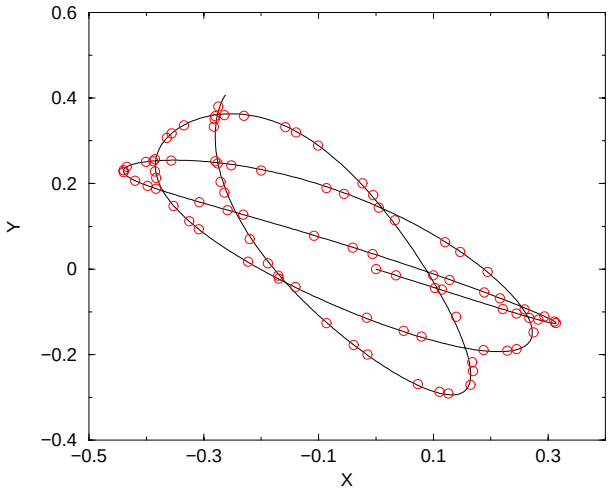

Figure 3. Discrete Integrable Henon–Heiles with a variable step-size.

5 Conclusion

In this paper a new numerical integration algorithm for the integrable Henon–Heiles system is designed with the help of canonical transformation. All of the constants of motion are then exactly conserved. This property is rather different from the known numerical integrators of the integrable Henon–Heiles system. Other types of the integrable Henon–Heiles systems [8] can be discretized in the same method.

There are some additional advantages of the integrable Henon–Heiles system. As is observed in numerical examples, the orbit of the discrete integrable Henon–Heiles gives a better approximation than the symplectic Euler scheme. Secondly, a variable step time is naturally assigned to the discrete integrable Henon–Heiles system. Using the new stable numerical integration algorithm, the authors wish to discretize some other integrable Hamiltonian systems besides the integrable Henon–Heiles system and the two-dimensional Kepler motion.

A classification of Hankel determinant solutions of the restricted Toda chain equations is presented through polynomial Ansatz for moments. Each solution corresponds to the Sheffer class orthogonal polynomials. In turn, these solutions are equivalent to solutions with separated variables in Toda chain. These solutions lead naturally to explicit Hankel determinants of some combinatorial numbers.

1 Introduction

The Toda chain equations [17]

$$\dot{u}_n = u_n(b_n - b_{n-1}), \quad n = 1, 2, \dots, \qquad \dot{b}_n = u_{n+1} - u_n, \quad n = 0, 1, \dots \tag{1}$$

with additional condition

$$u_0 = 0 \tag{2}$$

has the well-known relation with the theory of orthogonal polynomials, where the dot indicates the differentiation with respect to t. In what follows we will call equations (1) with restriction (2) *the restricted Toda chain* (TC) equations.

Let $P_n(x;t)$ be orthogonal polynomials satisfying the three-term recurrence relation

$$P_{n+1}(x) + b_n P_n(x) + u_n P_{n-1}(x) = xP_n(x), \qquad n = 1, 2, \dots \tag{3}$$

with initial conditions

$$P_0 = 1, \qquad P_1(x) = x - b_0. \tag{4}$$

We will assume that $u_n \neq 0$, $n = 1, 2, \dots$. Then, by the Favard theorem [4], there exists a nondegenerate linear functional σ such that the polynomials $P_n(x)$ are orthogonal with respect to it:

$$\sigma(P_n(x)P_m(x)) = h_n\delta_{nm}, \tag{5}$$

where h_n are normalization constants. The linear functional σ can be defined through its moments

$$c_n = \sigma(x^n), \qquad n = 0, 1, \dots. \tag{6}$$

It is usually assumed that $c_0 = 1$ (standard normalization condition), but we will not assume this condition in the followings. So we will assume that c_0 is an arbitrary nonzero parameter.

Introduce the Hankel determinants

$$D_n = \det(c_{i+j})_{i,j=0,\dots,n-1}, \qquad D_0 = 1, \qquad D_1 = c_0. \tag{7}$$

Then the polynomials $P_n(x)$ can be uniquely represented as [4]

$$P_n(x) = \frac{1}{D_n} \begin{vmatrix} c_0 & c_1 & \cdots & c_n \\ c_1 & c_2 & \cdots & c_{n+1} \\ \cdots & \cdots & \cdots & \cdots \\ c_{n-1} & c_n & \cdots & c_{2n-1} \\ 1 & x & \cdots & x^n \end{vmatrix}. \tag{8}$$

The normalization constants are expressed as

$$h_n = \frac{D_{n+1}}{D_n}, \qquad h_0 = D_1 = c_0. \tag{9}$$

While the recurrence coefficients u_n satisfy the relation

$$u_n = \frac{h_n}{h_{n-1}} = \frac{D_{n-1}D_{n+1}}{D_n^2}. \tag{10}$$

Thus we have

$$h_n = c_0 u_1 u_2 \cdots u_n. \tag{11}$$

Then we have

Theorem 1. *The following statements are equivalent.*

(i) *The recurrence coefficients u_n, b_n satisfy the TC equations* (1) *with the restriction $u_0 = 0$ (i.e. $\dot b_0 = u_1$).*

(ii) *The corresponding orthogonal polynomials $P_n(x;t)$ satisfy the relation*

$$\dot P_n(x;t) = -u_n P_{n-1}(x;t). \tag{12}$$

(iii) *The moments c_n satisfy the relation*

$$\dot c_n = c_{n+1} + \frac{\dot c_0 - c_1}{c_0} c_n, \tag{13}$$

where $c_0(t)$ is an arbitrary differentiable function of t.

See [1, 13], for the proof of this theorem.

We note only that it is commonly assumed that $c_0(t) \equiv 1$, but in what follows we will choose another normalization condition

$$\dot c_0 = c_1. \tag{14}$$

Then the condition (13) becomes very simple

$$\dot c_n = c_{n+1}, \tag{15}$$

or, equivalently,

$$c_n(t) = \frac{d^n c_0(t)}{dt^n}. \tag{16}$$

Hence, for the Toda chain case, the Hankel determinants $D_n = D_n(t)$ have the form

$$D_n = \det(c_0^{(i+k)})_{i,k=0,\dots,n-1}, \qquad D_0 = 1, \qquad D_1 = c_0, \tag{17}$$

where $c_0^{(j)}$ means the j-th derivative of $c_0(t)$ with respect to t.

Now we have

Proposition 1. *The restricted TC equations are equivalent also to the equations*

$$\frac{d^2 \log D_n}{dt^2} = \frac{D_{n-1} D_{n+1}}{D_n^2}, \qquad n = 1, 2, \dots . \tag{18}$$

Proof of this proposition is almost obvious. Equations (18) are equivalent to the Hirota bilinear form [6] for the restricted TC equations which was analyzed by many authors (see, e.g. [2, 11]). The parametric determinants such as $D_n(t)$ have played a very fundamental role in the Hirota–Sato theory of integrable dynamical systems as tau-functions. As was noticed in [15,18] the relation (18) for the Hankel determinants of type (17) with (15) was firstly obtained by Sylvester and is known today as the Sylvester theorem [9].

Note also that for the Hankel determinants of the form (17) we have two useful relations

$$b_n = \frac{\dot{D}_{n+1}}{D_{n+1}} - \frac{\dot{D}_n}{D_n} \tag{19}$$

and

$$\dot{h}_n = h_n b_n. \tag{20}$$

In particular, for $n = 0$ we have from (20)

$$b_0 = \frac{\dot{c}_0}{c_0}. \tag{21}$$

The relation (21) allows us to restore $c_0(t)$ if the recurrence coefficient $b_0 = b_0(t)$ is known explicitly from Toda chain solutions (1).

In this paper we consider a class of explicit solutions of the restricted TC equations through a separation of variables $c_n(t)$. Such solutions correspond to the Sheffer class orthogonal polynomials such as the Meixner, Pollaczek, Laguerre, Charlier and Hermite polynomials. It is shown that Hankel determinants of some combinatorial numbers, such as the Euler, the binomial coefficients and Bell numbers, are then presented.

2 Generating functions of the moments

In the theory of orthogonal polynomials the Stieltjes function $F(z)$ is defined as a generating function of the moments [4]

$$F(z) = \frac{c_0}{z} + \frac{c_1}{z^2} + \cdots + \frac{c_n}{z^{n+1}} + \cdots . \tag{22}$$

If moments c_n depend on t according to the Toda Ansatz (15), we then have

$$\dot{F}(z;t) = \frac{c_1}{z} + \frac{c_2}{z^2} + \cdots + \frac{c_n}{z^n} + \cdots = zF(z) - c_0. \tag{23}$$

In fact, the relation (23) is equivalent to restricted TC equations (15).

We consider also a generating function of another type:

$$\Phi(p) = \sum_{k=0}^{\infty} c_k \frac{p^k}{k!}. \tag{24}$$

Note that in number theory for a given sequence of numbers c_n the generating function of type (22) is called a G-function, and the generating function of type (24) is called an E-function [5]. The relationship between functions $F(z)$ and $\Phi(p)$ is known and is given by the (formal) Laplace transform:

$$F(z) = \sum_{k=0}^{\infty} c_k z^{-k-1} = \sum_{k=0}^{\infty} c_k \int_0^{\infty} \frac{p^k e^{-pz}}{k!} dp = \int_0^{\infty} e^{-pz} \Phi(p) dp. \tag{25}$$

For the case of the restricted TC equations with condition (15) we see that generating function $\Phi(p)$ is given automatically by the formal Taylor expansion

$$\Phi(p;t) = \sum_{k=0}^{\infty} c_k(t)\frac{p^k}{k!} = \sum_{k=0}^{\infty} c_0^{(k)}(t)\frac{p^k}{k!} = c_0(t+p) \tag{26}$$

of $c_0(t+p)$. Thus the E-generating function is given just by the shifted $c_0(t+p)$ zero-moment function. The Stieltjes function is given then as the Laplace transform

$$F(z;t) = \int_0^{\infty} e^{-pz} c_0(t+p)dp. \tag{27}$$

3 Special polynomial Ansatz and separated variables

In this section we describe concrete examples of the E-generating functions $c_0(t)$ (26) which stem from special Ansatz for functional structure of the moments $c_n(t)$. Namely, we assume a separation of variables as follows

$$c_n(t) = T_n(y(t))c_0(t), \qquad n = 0, 1, \ldots, \tag{28}$$

where $T_n(y(t))$ is a polynomial of exactly degree n of some (unknown) variable $y(t)$. Note that in [7,8] some systems of orthogonal polynomials were considered having moments as orthogonal polynomials from some variable. In our approach we *do not* require that $T_n(y)$ be orthogonal polynomials.

The main result is

Theorem 2. *In order to Ansatz* (28) *be compatible with the restricted TC equations it is necessary and sufficient that the function $y(t)$ be a solution of the equation*

$$\dot{y}(t) = \sigma(y), \tag{29}$$

where $\sigma(y)$ is a (nonzero) polynomial in y with degree less or equal 2,

$$\sigma(y) = \xi y^2 + \eta y + \zeta, \tag{30}$$

and the function $\phi(y) = c_0(t(y))$ be a solution of the equation

$$\phi'(y) = \frac{\tau(y)}{\sigma(y)}\phi(y), \tag{31}$$

where $\tau(y)$ is a polynomial of exactly first degree,

$$\tau(y) = \alpha y + \beta \tag{32}$$

with $\alpha \neq 0$ and β arbitrary parameters, and $t(y)$ is the inverse function with respect to $y(t)$. The restriction between α and ξ, $\xi \neq -\alpha/n$, $n = 1, 2, \ldots$, is assumed.

It is possible also to find explicit expression for the recurrence coefficients:

Proposition 2. *If moments $c_n(t)$ satisfy the polynomial Ansatz (28) then the recurrence coefficients $u_n(t)$, $b_n(t)$ have the explicit expressions*

$$\begin{aligned} b_n(t(y)) &= \tau(y) + n\sigma'(y), \\ u_n(t(y)) &= n\sigma(y)\left(\tau'(y) + \frac{1}{2}(n-1)\sigma''(y)\right) = n\sigma(y)(\alpha + (n-1)\xi). \end{aligned} \tag{33}$$

Proof of this proposition is an elementary application of induction.

We see that the recurrence coefficient $u_n(t)$ has expression with separated variables:

$$u_n(t) = q(t)\kappa_n, \qquad n = 0, 1, \ldots, \tag{34}$$

where $q(t) = \sigma(y(t))$ depends only on t and $\kappa_n = n(\alpha + (n-1)\xi)$ depends only on n.

It is possible to prove an inverse theorem

Theorem 3. *Two Ansatzes* (28) *and* (34) *(with the restriction* $\kappa_0 = 0$*) for solutions of the restricted TC equations are equivalent.*

Such solutions were constructed in [12] and [19]. They were also rediscovered in [3]. In [19] and [3] it was established, that corresponding polynomials belong to the Sheffer class.

4 Hankel determinants of some combinatorial numbers

In this section we consider some special cases of the general scheme of separated variables. Corresponding Toda solutions lead to simple determinantal formulas containing classical combinatorial numbers.

Case 1. $\sigma(y) = 1 - y^2$. For a special choice of parameters we have $\tau(y) = -y$ and $c_0 = 2e^t/(e^{2t}+1)$. For recurrence coefficients we have

$$b_n(t) = -(1+2n)\tanh(t), \qquad u_n(t) = -n^2\mathrm{sech}^2(t). \tag{35}$$

As discussed in [19, 3] this solution is related to the Meixner orthogonal polynomials.

It is to be noted that the moment $c_0(t)$ has an intimate relationship to the Euler numbers E_k, $k = 0, 1, 2, \ldots$, which are combinatorial numbers defined by

$$E_k = i^k \sum_{m=0}^{k} 2^m a_m \left(\begin{array}{c} k \\ m \end{array} \right), \qquad \frac{2}{e^t+1} = \sum_{k=0}^{\infty} a_m \frac{t^m}{m!}, \qquad i = \sqrt{-1}. \tag{36}$$

Here a_m are rational numbers and $\left(\begin{array}{c} k \\ m \end{array} \right)$ are binomial coefficients. Thus $c_0(t) = \Phi(2t; 1/2)$ and the coefficients $E_k(1/2)$ of the expansion

$$c_0(t) = \sum_{k=0}^{\infty} E_k(1/2) \frac{2^k t^k}{k!} \tag{37}$$

give the Euler numbers E_k through the relation $(2i)^k E_k(1/2) = E_k$.

Proposition 3. *The Hankel determinant of the Euler numbers is given by*

$$\det(E_{i+j})_{i,j=0,\ldots,n-1} = \left(\prod_{k=0}^{n-1} k! \right)^2. \tag{38}$$

Radoux [15] presented the Hankel determinant $\det(E_{2i+2j})_{i,j=0,\ldots,n-1} = \left(\prod_{k=0}^{n-1} (2k)! \right)^2$ of nonzero Euler numbers E_{2i+2j}.

Case 2. $\sigma(y) = -(y-1)^2$. In this case $\sigma(y)$ has a real root of multiplicity 2. For a special choice of parameters we have

$$b_n(t) = -z + \frac{\alpha - 2n}{t+1}, \qquad u_n(t) = \frac{n(n-\alpha-1)}{(t+1)^2}. \tag{39}$$

with some parameter z. These coefficients correspond to the Laguerre polynomials. Then we obtain

$$c_0(t) = (t+1)^\alpha e^{-zt+z}. \tag{40}$$

Expression $(t+1)^\alpha e^{-zt}$ is a generating function of the Laguerre polynomials ${L_k}^{\alpha-k}(z)$:

$$(t+1)^\alpha e^{-zt} = \sum_{k=0}^{\infty} {L_k}^{\alpha-k}(z) t^k.$$

From this relation it follows that ${L_k}^{\alpha-k}(0) = \binom{\alpha}{k}$ are (generalized) binomial coefficients.

Let us consider the Hankel determinant of the generating function of the generalized binomial coefficients ${L_k}^{\alpha-k}(0)$

$$\begin{aligned} &D_n(t) = \det(d_{i+j}(t))_{i,j=0,\dots,n-1}, \qquad D_0(t) = 1, \qquad D_1(t) = d_0, \\ &d_0(t) = (t+1)^\alpha, \qquad d_n(t) = \frac{d^n d_0(t)}{dt^n}. \end{aligned} \tag{41}$$

Proposition 4. *The Hankel determinant of the generalized binomial coefficients* ${L_k}^{\alpha-k}(0)$ *is given by*

$$D_n(0) = (-1)^{[n/2]} \prod_{k=1}^{n-1} k!(\alpha-k+1)^{n-k}. \tag{42}$$

Case 3. $\sigma(y) = y+1$. For special choice of parameters the solution of the restricted TC equations is

$$b_n(t) = u_n(t) = ne^t \tag{43}$$

which corresponds to the Charlier orthogonal polynomials [19].

For $c_0(t)$ we have

$$c_0(t) = \exp\left(e^t - 1\right).$$

This expression coincides with the generating function of the Bell numbers B_k. Namely,

$$c_0(t) = \sum_{k=0}^{\infty} B_k \frac{t^k}{k!}, \qquad B_k = \sum_{m=0}^{k} S(k,m), \tag{44}$$

where $S(k,m)$ is the Stirling numbers of the second kind. Thus $B_k = c_0^{(k)}(t)$. It is known [15] that the associated Hankel determinants

$$D_n(t) = \det(c_0^{(i+j)}(t))_{i,j=0,\dots,n-1} \qquad \text{and} \qquad D_n(0) = \det(B_{i+j})_{i,j=0,\dots,n-1}$$

are

$$\begin{aligned} &D_n(t) = \prod_{k=0}^{n-1} k! \cdot \exp\left(\frac{n(n-1)}{2} t + ne^t - n\right), \\ &D_n(0) = \prod_{k=0}^{n-1} k!, \end{aligned} \tag{45}$$

respectively.

Case 4. $\sigma(y) = 1$. In this case we have (shifted) Hermite polynomials:

$$b_n(t) = -2t + 2z, \qquad u_n(t) = -2n. \tag{46}$$

The E-generating function

$$c_0(t) = \exp\left(-t^2 + 2zt\right) \tag{47}$$

of the Hermite polynomials $H_k(z)$ is derived, namely,

$$c_0(t) = \sum_{k=0}^{\infty} H_k(z)\frac{t^k}{k!}. \tag{48}$$

The Hankel determinants $D_n = \det(H_{i+j}(z))_{i,j=0,\ldots,n-1}$ of Hermite polynomials is found in Radoux [14] by an alternative way. The result is

$$D_n = \det(H_{i+j}(z))_{i,j=0,\ldots,n-1} = (-2)^{n(n-1)} \prod_{k=0}^{n-1} k!. \tag{49}$$

Note that D_n is independent of z.

Thus the Hankel determinants of some combinatorial numbers can be easily calculated explicitly from corresponding Toda solutions with separated variables.

Operators of Binary Darboux Transformations for Dirac's System

Marta POCHYNAYKO † *and Yuriy SYDORENKO* ‡

† *Institute of Applied Mathematics and Fundamental Sciences, National University "Lvivska Politechnika", 12 S. Bandery Str., 79013 Lviv, Ukraine*

‡ *Franko Lviv National University, 1 Universytets'ka Str., 79000 Lviv, Ukraine*
E-mail: *matmod@franko.lviv.ua*

It is shown that the binary Darboux transformations (BDT) [1–4] for Dirac's operator generate transformations operators obtained by L.P. Nizhnik by considering inverse scattering problem of Dirac's system [5,6]. We found a wide set of explicit solutions of the space-two-dimensional non-linear Schrödinger equation. It is shown that solutions of those equations obtained by inverse scattering method are contained among those obtained by binary Darboux transformations method.

Let us consider Dirac's operator L of the form

$$L = \begin{pmatrix} \partial_x & u_1 \\ u_2 & \partial_y \end{pmatrix}, \quad u_1 = u_1(x,y), \quad u_2 = u_2(x,y), \quad \partial_x := \frac{\partial}{\partial x}, \quad \partial_y := \frac{\partial}{\partial y}. \tag{1}$$

Let 1. $Y = \begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix}$ be arbitrary and

$$\varphi = \begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix} := \begin{pmatrix} \varphi_{11} & \cdots & \varphi_{1K} \\ \varphi_{21} & \cdots & \varphi_{2K} \end{pmatrix}$$

some fixed $(2 \times K)$-matrix solutions of Dirac's system

$$LY = 0. \tag{2}$$

2. $Z = \begin{pmatrix} Z_1 \\ Z_2 \end{pmatrix}$ be arbitrary and

$$\psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} := \begin{pmatrix} \psi_{11} & \cdots & \psi_{1K} \\ \psi_{21} & \cdots & \psi_{2K} \end{pmatrix}$$

some fixed $(2 \times K)$-matrix solutions of transposed system

$$L^\tau Z = 0, \; L^\tau = \begin{pmatrix} -\partial_x & u_2 \\ u_1 & -\partial_y \end{pmatrix}. \tag{3}$$

3.

$$\Omega[Z, Y, M_0, M] := \Omega[Z, Y] \tag{4}$$

is a matrix potential which satisfies the condition $\Omega[Z, Y, M_0, M_0] = 0$, where $M = (x, y)$, $M_0 = (x_0, y_0) \in \overline{\mathbb{R}^2}$.

Remark 1. From equations (2), (3) for arbitrary solutions Y, Z the relation $(Z_1^\top Y_1)_x = -(Z_2^\top Y_2)_y$ follows, which ensures the existence (up to an arbitrary constant) of the matrix potential

$$\Omega: \; \Omega_x = -Z_2^\top Y_2, \;\; \Omega_y = Z_1^\top Y_1.$$

4. Let C be some $(K \times K)$-constant matrix and the potential $C + \Omega[\psi, \varphi]$ is non-generated in a neighborhood of $M_0 = (x_0, y_0) \in \overline{\mathbb{R}^2}$.

By the direct computation we prove the following proposition.

Proposition 1. *The integral operator W defined on the space of solutions of Dirac's system by the formula*

$$WY := Y - \varphi(C + \Omega[\psi, \varphi])^{-1}\Omega[\psi, Y] \tag{5}$$

transforms Dirac's operator (1) *into Dirac's operator $\hat{L} = WLW^{-1}$ of the form*

$$\hat{L} = \begin{pmatrix} \partial_x & \hat{u}_1 \\ \hat{u}_2 & \partial_y \end{pmatrix},$$

where

$$\begin{aligned} \hat{u}_1 &= u_1 - \varphi_1(C + \Omega[\psi, \varphi])^{-1}\psi_2^\top, \\ \hat{u}_2 &= u_2 + \varphi_2(C + \Omega[\psi, \varphi])^{-1}\psi_1^\top. \end{aligned} \tag{6}$$

The functions $\hat{Y} := WY$ is the general solution of Dirac's system

$$\hat{L}\hat{Y} = 0$$

with the coefficients (potentials) $\hat{u}_1$, $\hat{u}_2$ (6).

Remark 2. The (2×2)-matrix integral operator $W - I$ is of the form

$$W - I := \begin{pmatrix} W_{11} & W_{12} \\ W_{21} & W_{22} \end{pmatrix}, \tag{7}$$

where operators W_{ij} are defined by their kernels $W_{ij}(x, y, s)$, $i, j = 1, 2$ depending on concrete realization of potential $\Omega[Z, Y]$, are the Volterra operators of variables x and y. The coefficients $\hat{u}_1$, $\hat{u}_2$ (6) are defined as the diagonals of kernels of the operators W_{12}, W_{21} respectively.

Remark 3. It is not difficult to show that formulas (6) give solutions of space-two-dimensional non-linear Schrödinger equations [6, 7]

$$\begin{aligned} &u_{1t} + u_{1xx} + u_{1yy} - 2(v_1 - v_2)u_1 = 0, \\ &u_{2t} - u_{2xx} - u_{2yy} - 2(v_2 - v_1)u_2 = 0, \\ &v_{1x} = (u_1 u_2)_y, \qquad v_{2y} = (u_1 u_2)_x, \end{aligned} \tag{8}$$

which has the Lax representation $[L, A] = 0$, where L is Dirac's operator (1), and A is some matrix evolution operator [2]. The functions φ, ψ in solutions (6) depend on parameter t in view of the equations

$$A\varphi = 0, \qquad A^\tau \psi = 0.$$

In this paper we show that certain realization of the operator W (5), which is generated by concrete choice of potential (4), coincides with transformation operators for Dirac's systems which were obtained in the papers [5, 6].

Let us consider the operator W defined by the following formula

$$\begin{aligned} \hat{Y} = WY = Y - \varphi &\left[C + \int_{x_0}^{x} (-\psi_2^\top \varphi_2)\, dx + \int_{y_0}^{y} \psi_1^\top \varphi_1\, dy\right]^{-1} \\ &\times \left(\int_{x_0}^{x} (-\psi_2^\top Y_2)\, dx + \int_{y_0}^{y} \psi_1^\top Y_1\, dy\right). \end{aligned} \tag{9}$$

Respectively, the kernels of the operators W_{12}, W_{21} (7) have the form

$$W_{12}(x,y,s) = \varphi_1(x,y)\left[C - \int_{x_0}^{x} \psi_2^\top \varphi_2(x,y_0)\,dx + \int_{y_0}^{y} \psi_1^\top \varphi_1(x,y)\,dy\right]^{-1} \psi_2^\top(s,y),$$
$$W_{21}(x,y,s) = -\varphi_2(x,y)\left[C - \int_{x_0}^{x} \psi_2^\top \varphi_2(x,y_0)\,dx + \int_{y_0}^{y} \psi_1^\top \varphi_1(x,y)\,dy\right]^{-1} \psi_1^\top(x,s), \qquad (10)$$

and the coefficients $\hat{u}_1$, $\hat{u}_2$ can be written

$$\hat{u}_1 = u_1(x,y) - W_{12}(x,y,x),$$
$$\hat{u}_2 = u_2(x,y) + W_{21}(x,y,y). \qquad (11)$$

In the case when Dirac's operator is non-perturbed ($u_1 = u_2 \equiv 0$), the solutions φ, ψ of equations (2), (3) admit evidently, such forms

$$\varphi = \begin{pmatrix} -f_1(y) & 0 \\ 0 & g_2(x) \end{pmatrix}, \qquad f_1 = (f_{11},\dots,f_{1n}), \qquad g_2 = (g_{21},\dots,g_{2n}),$$
$$\psi = \begin{pmatrix} g_1(y) & 0 \\ 0 & -f_2(x) \end{pmatrix}, \qquad g_1 = (g_{11},\dots,g_{1n}), \qquad f_2 = (g_{21},\dots,f_{2n}).$$

Let a $(2n \times 2n)$-matrix C be of the form

$$C = \begin{pmatrix} 0 & I_n \\ I_n & 0 \end{pmatrix}, \qquad I_n := \operatorname{diag}(1,\dots,1),$$
$$M_0 := (x_0,y_0) = (-\infty,+\infty), \qquad Y_1 = Y_1(y) := Y_1(-\infty,y), \qquad Y_2 = Y_2(x) := Y_2(x,+\infty).$$

By formula (9) we obtain

$$\begin{pmatrix} \hat{Y}_1 \\ \hat{Y}_2 \end{pmatrix} := WY = \begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix} - \begin{pmatrix} -f_1(y) & 0 \\ 0 & g_2(x) \end{pmatrix}$$
$$\times \begin{pmatrix} -\int_{+\infty}^{y} g_1^\top f_1(y)\,dy & I_n \\ I_n & \int_{-\infty}^{x} f_2^\top g_2(x)\,dx \end{pmatrix}^{-1} \left(\int_{-\infty}^{x} (f_2^\top Y_2)\,dx + \int_{+\infty}^{y} g_1^\top Y_1\,dy\right).$$

By using the known formula

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}^{-1} = \begin{pmatrix} A_{11}^{-1}(I + A_{12}T^{-1}A_{21}A_{11}^{-1}) & -A_{11}^{-1}A_{12}T^{-1} \\ -T^{-1}A_{21}A_{11}^{-1} & T^{-1} \end{pmatrix}$$

for a block matrix A, where $T = A_{22} - A_{21}A_{11}^{-1}A_{12}$ and provided that $A_{12} = A_{21} = I_n$, we obtain

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}^{-1} = \begin{pmatrix} -[I_n - A_{22}A_{11}]^{-1}A_{22} & [I_n - A_{22}A_{11}]^{-1} \\ [I_n - A_{11}A_{22}]^{-1} & -[I_n - A_{11}A_{22}]^{-1}A_{11} \end{pmatrix}.$$

Respectively, the operator W is of the form

$$W = I - \begin{pmatrix} -f_1 & 0 \\ 0 & g_2 \end{pmatrix} \begin{pmatrix} -[I_n - A_{22}A_{11}]^{-1}A_{22} & [I_n - A_{22}A_{11}]^{-1} \\ [I_n - A_{11}A_{22}]^{-1} & -[I_n - A_{11}A_{22}]^{-1}A_{11} \end{pmatrix}$$
$$\times \begin{pmatrix} -\int_{+\infty}^{y} g_1^\top \cdot\, dy & 0 \\ 0 & \int_{-\infty}^{x} f_2^\top \cdot\, dx \end{pmatrix}, \qquad (12)$$

which coincides with respective transformation operators for Dirac's system obtained in paper [6]. The kernels (10) of the operators W_{12}, W_{21} in formula (12) are

$$W_{12}(x,y,s) = f_1(y)\left[I + \int_{-\infty}^{x} f_2^{\top} g_2(x)\,dx \int_{+\infty}^{y} g_1^{\top} f_1(y)\,dy\right]^{-1} f_2^{\top}(s),$$
$$W_{21}(x,y,s) = g_2(x)\left[I + \int_{+\infty}^{y} g_1^{\top} f_1(y)\,dy \int_{-\infty}^{x} f_2^{\top} g_2(x)\,dx\right]^{-1} g_1^{\top}(s).$$

The solution $\hat{u}_1$, $\hat{u}_2$ (6) of equations (8) by the formulas (11) coincide with the corresponding solution obtained by inverse scattering method [6, 7].

Quasigraded Lie Algebras and Matrix Generalization of Landau–Lifshitz Equation

Taras V. SKRYPNYK

Bogoliubov Institute for Theoretical Physics, 14-b Metrologichna Str., 03143 Kyiv-143, Ukraine
E-mail: *tskrypnyk@imath.kiev.ua*

Using special quasigraded Lie algebras we obtain new hierarchies of integrable equations in partial derivatives admitting zero-curvature representations. In particular, we obtain generalization of Landau–Lifshitz equation for the Lie algebras $so(2n)$, $sp(n)$ and $gl(n)$.

1 Introduction

Integrability of equations of $1+1$ field theory and condensed matter physics is based on the possibility to represent them in the form of the so-called zero-curvature equations [1, 2]:

$$\frac{\partial U(x,t,\lambda)}{\partial t} - \frac{\partial V(x,t,\lambda)}{\partial x} + [U(x,t,\lambda), V(x,t,\lambda)] = 0. \tag{1}$$

The most productive interpretation of zero-curvature equation (see [6, 5]) is to consider them as a consistency condition for a set of a commuting Hamiltonian flows on the dual space to some infinite-dimensional Lie algebra $\widetilde{\mathfrak{g}}$ of matrix-valued function of λ written in the Euler–Arnold (generalized Lax) form:

$$\frac{\partial L(\lambda)}{\partial t_l} = \mathrm{ad}^*_{\nabla I_l(L(\lambda))} L(\lambda), \qquad \frac{\partial L(\lambda)}{\partial t_k} = \mathrm{ad}^*_{\nabla I_k(L(\lambda))} L(\lambda), \tag{2}$$

where $L(\lambda) \in \widetilde{\mathfrak{g}}^*$ is the generic element of the dual space, $\nabla I_k(L(\lambda)) \in \widetilde{\mathfrak{g}}$ is algebra-valued gradient of $I_k(L(\lambda))$, and the "Hamiltonians" $I_k(L(\lambda))$, $I_l(L(\lambda))$ belong to the set of mutually commuting with respect to the natural Lie–Poisson bracket functions on $\widetilde{\mathfrak{g}}^*$.

Consistency condition of two commuting flows given by equations (2) yields equation (1) with $U \equiv \nabla I_k$, $V \equiv \nabla I_l$, $t_k \equiv x$, $t_l \equiv t$. Hence in order to construct new integrable hierarchies in the framework of the described approach it is necessary to have some infinite-dimensional Lie algebra $\widetilde{\mathfrak{g}}$ admitting an algorithm of construction of infinite family of commuting Hamiltonians on its dual space. Such the algorithm is famous Kostant–Adler scheme [3, 4].

In our previous paper [9] we proposed a multiparametric family of special quasigraded Lie algebras $\widetilde{\mathfrak{g}}_A$ parametrized by numerical matrices A. The main feature of the constructed Lie algebras is the property to admit Kostant–Adler scheme, i.e. to admit decomposition into the sum of two subalgebras $\widetilde{\mathfrak{g}}_A = \widetilde{\mathfrak{g}}_A^+ + \widetilde{\mathfrak{g}}_A^-$. In the present paper we use them in order to construct new sets of integrable equations in partial derivatives. In the result we obtain an infinite set of equations (1) with $\widetilde{\mathfrak{g}}_A^{\pm}$-valued $U - V$ pairs constituting so-called integrable hierarchies. We concentrate our attention on one of these hierarchies connected with the subalgebras $\widetilde{\mathfrak{g}}_A^-$.

In the present paper we show that explicit form of the corresponding equations depends on the form of the additional covariant constraint on the matrices entering into the U-operators. We consider the simplest U-operators and the simplest covariant matrix constraint:

$$U = \lambda^{-1} S, \qquad S^2 = \frac{1}{4}\mathbf{1}.$$

Such covariant constraints exist for the cases of underlying simple (reductive) matrix Lie algebras $\mathfrak{g}$ are $so(2n)$, $sp(n)$ and $gl(n)$. In the result we obtain the following equation on the matrix S:

$$\frac{\partial S}{\partial t} = \left[S, \frac{\partial^2 S}{\partial x^2}\right] + \frac{1}{2}\frac{\partial}{\partial x}(AS + SA) + \left[S, \left[S, \frac{\partial S}{\partial x}\right]\right]_A + \frac{1}{2}[S, AS + SA]_A. \tag{3}$$

We show that this equation is the direct matrix generalization of the Landau–Lifshiz equation, where the role of the anisotropy tensor is played by the matrix A. In the case of $\mathfrak{g} = so(4)$ it could be reduced to the standard Landau–Lifshitz equation [15, 5].

The volume of the paper gives no possibility to consider other equations connected with algebras $\widetilde{\mathfrak{g}}_A$. Interested reader may consult our papers [10, 11] for further examples.

2 Special quasi-graded algebras

In this section we describe a new class of infinite-dimensional Lie algebras $\widetilde{\mathfrak{g}}$ that could be used to generate classical integrable systems. These algebras satisfy the following integrability requirements (IR):

- (IR1) they possess infinite number of algebraically independent invariants of coadjoint representation,
- (IR2) they are decomposable into the direct sum of two subalgebras: $\widetilde{\mathfrak{g}} = \widetilde{\mathfrak{g}}^- + \widetilde{\mathfrak{g}}^+$,
- (IR3) subalgebras $\widetilde{\mathfrak{g}}^+$, $\widetilde{\mathfrak{g}}^-$ possess infinite set of embedded ideals $\mathcal{J}_{\pm n}$ of finite co-dimensions.

2.1 General construction

Definition 1. Infinite-dimensional Lie algebra $\widetilde{\mathfrak{g}}$ is called $\mathbb{Z}$-quasigraded of type (p, q) if it admits the decomposition:

$$\widetilde{\mathfrak{g}} = \sum_{j\in\mathbb{Z}} \mathfrak{g}_j, \quad \text{such that} \quad [\mathfrak{g}_i, \mathfrak{g}_j] \subset \sum_{k=-p}^{q} \mathfrak{g}_{i+j+k}.$$

The following proposition holds true [9]:

Proposition 1. *Let $\widetilde{\mathfrak{g}}$ be $\mathbb{Z}$-quasi graded of type $(0, 1)$, or $(1, 0)$. Then $\widetilde{\mathfrak{g}}$ satisfies conditions* (IR2) *and* (IR3).

So our aim in this section will be a construction of $\mathbb{Z}$-quasigraded algebras of type $(0, 1)$. For this purpose we will deform Lie algebraic structure in loop algebras. We will introduce into $L(\mathfrak{g}) = \mathfrak{g} \otimes \mathrm{Pol}\,(\lambda, \lambda^{-1})$ new Lie bracket:

$$[X \otimes p(\lambda), Y \otimes q(\lambda)]_F = [X, Y] \otimes p(\lambda)q(\lambda) - F(X, Y) \otimes \lambda p(\lambda)q(\lambda), \tag{4}$$

where $X, Y \in \mathfrak{g}$, $p(\lambda), q(\lambda) \in \mathrm{Pol}\,(\lambda, \lambda^{-1})$, $[\,,\,]$ in the righthand side of this identity denotes ordinary Lie bracket in $\mathfrak{g}$ and map $F : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$ is skew. It is evident by the very construction that the Lie algebras with the so defined bracket are $\mathbb{Z}$-quasigraded Lie algebras of type $(0, 1)$ with the quasigrading being defined by degrees of the spectral parameter λ.

The following Propositions answer the question of when bracket (4) satisfy the Jacobi identity:

Proposition 2. *For bracket* (4) *to satisfy the Jacobi identities the cochain F should satisfy the following two requirements:*

$$\text{(J1)} \quad \sum_{\text{c.p. } \{i,j,k\}} (F([X_i, X_j], X_k) + [F(X_i, X_j), X_k]) = 0,$$

$$\text{(J2)} \quad \sum_{\text{c.p. } \{i,j,k\}} F(F(X_i, X_j), X_k) = 0.$$

In the case of classical matrix Lie algebras it is possible to give an explicit construction of large (multiparametric) family of cochains F, that satisfy conditions (J1)–(J2). Let $\mathfrak{g}$ be hereafter a classical matrix Lie algebra of the type $gl(n)$, $so(n)$ and $sp(n)$ over the field of the complex or real numbers. We will realize the algebra $so(n)$ as algebra of skew-symmetric matrices: $so(n) = \{X \in gl(n) | X = -X^\top\}$ and the algebra $sp(n)$ as the following matrix algebra: $sp(n) = \{X \in gl(n) | X = sX^\top s\}$, where n is an even number, $s \in so(n)$ and $s^2 = -1$.

The following Proposition holds true:

Proposition 3. *Let $\mathfrak{g}$ be a classical matrix Lie algebra over the field $\mathbb{K}$ of complex or real numbers. Let us define the numerical ($\mathbb{K}$-valued) $n \times n$ matrix A of the following type:*

1) *A is arbitrary for $\mathfrak{g} = gl(n)$,*
2) *$A = A^\top$ for $\mathfrak{g} = so(n)$,*
3) *$A = -sA^\top s$ for $\mathfrak{g} = sp(n)$.*

Then maps $F_A : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$ of the form $F_A(X, Y) = XAY - YAX$ are correctly defined skew-symmetric maps that satisfy conditions (J1)–(J2).

Remark 1. Cocycle F_A defines a second Lie bracket in the finite-dimensional Lie algebras $\mathfrak{g}$, that is compatible with the standard one. This fact was noticed in the paper [12] and was used to construct compatible Poisson brackets on the finite-dimensional Lie algebras $\mathfrak{g}$. The idea to use the same cocycle to generate infinite-dimensional Lie algebras with Kostant–Adler decomposition was proposed in [9] as a natural generalization of semi-geometric construction of [7, 8] of special quasigraded Lie algebras on the higher genus curves.

Definition 2. We will denote the Lie bracket in $\mathfrak{g}$ defined by the cocycles F_A by $[\,,\,]_A$, the corresponding finite-dimensional Lie algebra by $\mathfrak{g}_A$ and the infinite-dimensional Lie algebra with the Lie bracket given by (4) by $\widetilde{\mathfrak{g}}_A$.

The Lie bracket in the algebra $\widetilde{\mathfrak{g}}_A$ will have the following form:

$$[X(\lambda), (\lambda)]_{F_A} \equiv [X(\lambda), Y(\lambda)]_{A(\lambda)} = [X(\lambda), Y(\lambda)] - \lambda [X(\lambda), Y(\lambda)]_A, \tag{5}$$

where $X(\lambda), Y(\lambda) \in L(\mathfrak{g}) = \mathfrak{g} \otimes \mathrm{Pol}\,(\lambda, \lambda^{-1})$, $A(\lambda) \equiv 1 - \lambda A$, and we extend brackets $[\,,\,]$ and $[\,,\,]_A$ from the Lie algebra $\mathfrak{g}$ to the Lie algebra of $\mathfrak{g}$-valued functions $L(\mathfrak{g})$ in a natural way.

Now we can introduce convenient bases in the algebras $\widetilde{\mathfrak{g}}_A$. Due to the fact that we are dealing with matrix Lie algebras $\mathfrak{g}$, we will denote their basic elements as X_{ij}. For example, for the case $\mathfrak{g} = gl(n)$ we will have that $X_{ij} = I_{ij}$, where $(I_{ij})_{ab} = \delta_{ai}\delta_{bj}$ for the case $\mathfrak{g} = so(n)$ we will have that $X_{ij} = I_{ij} - I_{ji}$ etc. Let

$$X_{ij}^m \equiv X_{ij} \otimes \lambda^m$$

be the natural basis in $\widetilde{\mathfrak{g}}_A$. Commutation relations (5) in this basis have the following form:

$$[X_{ij}^r, X_{kl}^m]_{F_A} = \sum_{p,q} C_{ij,kl}^{pq} X_{pq}^{r+m} - \sum_{p,q} C_{ij,kl}^{pq}(A) X_{pq}^{r+m+1}, \tag{6}$$

where $C_{ij,kl}^{pq}$ and $C_{ij,kl}^{pq}(A)$ are the structure constants of the Lie algebras $\mathfrak{g}$ and $\mathfrak{g}_A$ respectively.

Remark 2. Algebra $\widetilde{\mathfrak{g}}_A$ could be realized also in the space of special matrix valued functions of λ with an ordinary Lie bracket $[\,,\,]$. Nevertheless we consider realization in the space $\mathfrak{g} \otimes \mathrm{Pol}\,(\lambda, \lambda^{-1})$ with the "deformed" bracket to be the most convenient.

2.2 Coadjoint representation and its invariants

In this subsection we define dual spaces, coadjoint representations and their invariants for the Lie algebras $\widetilde{\mathfrak{g}}_A$. Let us at first explicitly describe the dual space $\widetilde{\mathfrak{g}}_A^*$ of $\widetilde{\mathfrak{g}}_A$. For this purpose we will define the pairing between $\widetilde{\mathfrak{g}}_A$ and $\widetilde{\mathfrak{g}}_A^*$ in the following standard way:

$$\langle X, L\rangle = \operatorname*{res}_{\lambda=0} \operatorname{Tr}\left(X(\lambda)L(\lambda)\right). \tag{7}$$

The generic element of the dual space $L(\lambda) \in \widetilde{\mathfrak{g}}_A^*$ is written as follows:

$$L(\lambda) = \sum_{k\in\mathbb{Z}} \sum_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ij}^*. \tag{8}$$

The following proposition is true [9]:

Proposition 4. *The coadjoint action of $\widetilde{\mathfrak{g}}_A$ on $\widetilde{\mathfrak{g}}_A^*$ is written as follows:*

$$\operatorname{ad}^*_{X(\lambda)} \circ L(\lambda) = A(\lambda)X(\lambda)L(\lambda) - L(\lambda)X(\lambda)A(\lambda), \tag{9}$$

where $X(\lambda), Y(\lambda) \in \widetilde{\mathfrak{g}}_A$, $L(\lambda) \in \widetilde{\mathfrak{g}}_A^*$.

Remark 3. Note that linear spaces $\widetilde{\mathfrak{g}}_A$ and $\widetilde{\mathfrak{g}}_A^*$ do not coincide as $\widetilde{\mathfrak{g}}_A$-modules. Moreover, rigorously speaking, they also do not coincide as linear spaces, because $\widetilde{\mathfrak{g}}_A^*$ contains formal power series, and $\widetilde{\mathfrak{g}}_A$, by the very definition, consists of the Loran polynomials.

Proposition 4 has the following important corollary:

Corollary 1. *Let $L(\lambda)$ be the generic element of $\widetilde{\mathfrak{g}}_A^*$. Then the functions*

$$I_k^m(L(\lambda)) = \frac{1}{m} \operatorname*{res}_{\lambda=0} \lambda^{-(k+1)} \operatorname{Tr}\left(L(\lambda)A(\lambda)^{-1}\right)^m. \tag{10}$$

are invariants of the coadjoint representation of $\widetilde{\mathfrak{g}}_A$.

Remark 4. The matrix $A(\lambda)^{-1} \equiv (1-\lambda A)^{-1}$ has to be understood as a power series in λ in the neighborhood of 0 or ∞: $A(\lambda)^{-1} = (1+A\lambda+A^2\lambda^2+\cdots)$ or $A(\lambda)^{-1} = -(A^{-1}\lambda^{-1}+A^{-2}\lambda^{-2}+\cdots)$.

2.3 Lie–Poisson structure

Let us define the Poisson structures in the space $\widetilde{\mathfrak{g}}_A^*$ using the pairing $\langle\,,\,\rangle$ defined above. It defines Lie–Poisson (Kirillov–Kostant) bracket on $P(\widetilde{\mathfrak{g}}_{\mathcal{A}}^*)$ in the following standard way:

$$\{F(L(\lambda)), G(L(\lambda))\} = \langle L(\lambda), [\nabla F(L(\lambda)), \nabla G(L(\lambda))]\rangle, \tag{11}$$

where $\nabla F(L(\lambda)) = \sum\limits_{k\in\mathbb{Z}} \sum\limits_{i,j=1}^{n} \dfrac{\partial F}{\partial l_{ij}^{(k)}} X_{ij}^k$, $\nabla G(L) = \sum\limits_{m\in\mathbb{Z}} \sum\limits_{k,l=1}^{n} \dfrac{\partial G(\lambda)}{\partial l_{kl}^{(m)}} X_{kl}^m$.

From the Corollary 1 and standard arguments the next statement follows:

Proposition 5. *Functions $I_\phi^m(L(\lambda))$ are central for the Lie–Poisson bracket* (11).

Let us explicitly calculate Poisson bracket (11). It is easy to show that for the coordinate functions $l_{ij}^{(m)}$ these brackets will have the following form:

$$\{l_{ij}^{(n)}, l_{kl}^{(m)}\} = \sum_{p,q} C_{ij,kl}^{pq} l_{pq}^{(n+m)} - \sum_{p,q} C_{ij,kl}^{pq}(A) l_{pq}^{(n+m+1)}. \tag{12}$$

It is evident, that this bracket determine in the space of linear functions $\{l_{ij}^{(n)}\}$ a structure of the Lie algebra isomorphic to $\widetilde{\mathfrak{g}}_A$. That is why the corresponding Poisson algebra possesses decomposition into the direct sum of two Poisson subalgebras or by other words subspaces $(\widetilde{\mathfrak{g}}_A^{\pm})^*$ are Poisson.

3 Infinite-dimensional Hamiltonian systems via K-A admissible Lie algebras

In the previous section we have constructed infinite-dimensional Lie algebras $\widetilde{\mathfrak{g}}_A$ that have a decomposition into direct sum of two subalgebras and possess infinite set of invariants of coadjoint representation, i.e. admit so-called Kostant–Adler scheme. In the first subsection of this section we apply Kostant–Adler scheme to $\widetilde{\mathfrak{g}}_A$ in order to construct an infinite set of mutually commuting (with respect to the natural Lie–Poisson bracket) functions on the infinite-dimensional subalgebras $\widetilde{\mathfrak{g}}_A^{\pm}$. In the second subsection we will obtain zero-curvature type equations with $\widetilde{\mathfrak{g}}_A^{\pm}$-valued $U-V$ pairs.

3.1 Integrable Hamiltonian systems connected with algebras $\widetilde{\mathfrak{g}}_A^{\pm}$

Let $L^{\mp}(\lambda) \equiv \sum\limits_{i,j=1,n} L_{ij}^{\mp}(\lambda) X_{ji} = \sum\limits_{k\in\mathbb{Z}_{\pm}} \sum\limits_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ji}$ be the generic elements of the spaces $(\widetilde{\mathfrak{g}}_A^{\pm})^*$. Let us consider restriction of the invariant functions $\{I_k^m(L(\lambda))\}$ onto these subspaces. Note, that although Poisson subspaces $(\widetilde{\mathfrak{g}}_A^{\pm})^*$ are infinite-dimensional, all functions $\{I_k^m(L^{\pm}(\lambda))\}$ are polynomials, i.e. after restriction to $(\widetilde{\mathfrak{g}}_A^{\pm})^*$ no infinite sums appear in their explicit expressions. Corresponding Hamiltonian equations are written as:

$$\frac{\partial L_{ij}^{\mp}(\lambda)}{\partial t_k^m} = \{L_{ij}^{\mp}(\lambda), I_k^m(L^{\mp}(\lambda))\}. \tag{13}$$

The following important theorem holds true:

Theorem 1. (i) *Time flows defined by Hamiltonian equations* (13) *mutually commute.*
(ii) *Hamiltonian equations* (13) *are written in the "deformed" Lax form:*

$$\frac{\partial L^{\mp}(\lambda)}{\partial t_k^m} = A(\lambda) M_k^m(\lambda) L^{\mp}(\lambda) - L^{\mp}(\lambda) M_k^m(\lambda) A(\lambda), \tag{14}$$

where $M_k^m(\lambda) = \nabla I_k^m(L^{\mp}(\lambda)) \equiv \sum\limits_{s\in\mathbb{Z}_{\pm}} \sum\limits_{i,j=1}^{n} \dfrac{\partial I_k^m}{\partial l_{ij}^{(s)}} X_{ij}^s$ *is an algebra-valued gradient of* $I_k^m(L^{\mp}(\lambda))$.

(Proof of the theorem follows from the standard framework of the Kostant–Adler scheme [4].)

Remark 5. In this subsection we have obtained Hamiltonian systems of the Euler–Arnold type on the special infinite-dimensional Lie algebras possessing infinite number of the commuting integrals of motion. These Hamiltonian systems are "mechanical" because they are described by ordinary differential equations. Nevertheless we can consider our dynamical variables $l_{ij}^{(p)}$ to be functions of all time variables $t_k^{m\pm}$ and using the commutativity of all time flows obtain differential identities on functions $l_{ij}^{(p)}(t_k^{m\pm})$ that coincide with the integrable equations in partial derivatives. For this purpose in the next subsection we will derive zero-curvature equations.

3.2 "Deformed" zero curvature equations

In this section we will obtain zero curvature-type equations as compatibility conditions for the set of the commutative Hamiltonian flows constructed in the previous section. The following theorem holds true:

Theorem 2. *Let infinite-dimensional Lie algebras $\widetilde{\mathfrak{g}}_A$, $\widetilde{\mathfrak{g}}_A^{\pm}$, their dual spaces and polynomial Hamiltonians $I_k^m(L^{\pm}(\lambda))$, $I_l^n(L^{\pm}(\lambda))$ on them be defined as in previous sections. Then algebra-valued gradients of these functions satisfy the "deformed" zero-curvature equations:*

$$\frac{\partial \nabla I_k^m(L^{\pm}(\lambda))}{\partial t_l^{n\pm}} - \frac{\partial \nabla I_l^n(L^{\pm}(\lambda))}{\partial t_k^{m\pm}} + [\nabla I_k^m(L^{\pm}(\lambda)), \nabla I_l^n(L^{\pm}(\lambda))]_{A(\lambda)} = 0. \tag{15}$$

(Proof follows from the commutativity of two time flows defined by equations (14).)

Remark 6. By means of other realizations of $\widetilde{\mathfrak{g}}_A$ deformed zero-curvature equations can be rewritten in the form of the standard zero-curvature equations, but in this case corresponding $U-V$ pairs will be more complicated as functions of the spectral parameter λ.

Theorem 2 provides us with an infinite number of $\widetilde{\mathfrak{g}}_A^{\pm}$-valued $U-V$ pairs that satisfy zero curvature-type equations. The latter are non-linear equations in the partial derivatives on the dynamical variables – matrix elements of the matrices $L^{\pm}(\lambda)$. In the terminology of [2] equations generated by the infinite set of $U-V$ pairs are called "integrable in the kinematic sense". In the next subsections we will consider the simplest examples of such integrable equations and their hierarchies.

Now let us explain the technique of obtaining integrable equation in partial derivatives starting from zero-curvature equations. Let us at first note that in the described approach no "space" variable x is *a priori* singled out: all times $t_k^{m\pm}$ are equivalent. Fixation of the "space" flow is equivalent to the fixation of integrable hierarchy. For this purpose one should fix a Hamiltonian that generate x-flow. For the case of integrable systems, connected with algebras $\widetilde{\mathfrak{g}}_A^{\pm}$, this choice yields fixation of dynamical variables. In more details, for the dynamical variables in this case serve the matrix elements of $\nabla I_k^m(L^{\mp}(\lambda))$, where the Hamiltonian $I_k^m(L^{\mp}(\lambda))$ is chosen to generate an x-flow. Using zero-curvature conditions one can express matrix elements of all other matrix gradients $\nabla I_l^n(L^{\mp}(\lambda))$ via these dynamical variables and their derivatives with respect to the "space" coordinate. Substituting these expressions back to zero-curvature condition we obtain the desired equation in partial derivatives on the matrix elements of $\nabla I_k^m(L^{\mp}(\lambda))$.

4 Matrix generalization of L-L hierarchy

In this section we will obtain integrable hierarchies of differential equations in partial derivatives, admitting a zero curvature type representation (15) with the values in $\widetilde{\mathfrak{g}}_A^-$.

Let us consider dual space $(\widetilde{\mathfrak{g}}_A^-)^*$. Its generic element has the following form:

$$L^+(\lambda) = \sum_{k<0} \sum_{i,j=1,n} l_{ij}^{(k)} \lambda^{-(k+1)} X_{ji} = L^{(-1)} + \lambda L^{(-2)} + \lambda^2 L^{(-3)} + \lambda^3 L^{(-4)} + \cdots, \tag{16}$$

where $L^{(-k)} \equiv \sum\limits_{i,j=1,n} l_{ij}^{(-k)} X_{ji}$. Let us now calculate the Hamiltonians $I_k^m(L^+(\lambda))$. In order for the Hamiltonians $I_k^m(L^+(\lambda))$ to be polynomials we have to expand expression $A(\lambda)^{-1}$ in the power series in the neighborhood of zero:

$$A(\lambda)^{-1} = 1 + A\lambda + A^2\lambda^2 + \cdots.$$

From the results of the of the previous section it follows that the matrix gradients of Hamiltonians $I_k^m(L^+(\lambda))$ satisfy "deformed" zero-curvature equation (15). We will be interested in the two simplest Hamiltonians of the set $I_k^2(L^+(\lambda))$. By the direct calculations we obtain for them the following expressions:

$$I_0^2(L^+(\lambda)) = 1/2 \operatorname{Tr}\left(L^{(-1)}\right)^2, \qquad I_1^2(L^+(\lambda)) = \operatorname{Tr}\left(A\left(L^{(-1)}\right)^2\right) + \operatorname{Tr}\left(L^{(-1)}L^{(-2)}\right). \tag{17}$$

The corresponding matrix gradients are:

$$\nabla I_0^2(L^+(\lambda)) = L^{(-1)}\lambda^{-1},$$
$$\nabla I_1^2(L^+(\lambda)) = L^{(-1)}\lambda^{-2} + \big(\big(AL^{(-1)} + L^{(-1)}A\big) + L^{(-2)}\big)\lambda^{-1}. \tag{18}$$

As it follows from the said above, in order to fix an integrable hierarchy we should choose the Hamiltonian that generates an x-flow. In order to choose the simplest hierarchy we have to choose the Hamiltonian with the simplest matrix gradient. That is why we will take for such Hamiltonian the function $I_0^2(L^+(\lambda))$, putting $t_0^{2+} \equiv x$; $\nabla I_0^2(L^+(\lambda)) \equiv U(x,\lambda)$, $\nabla I_k^m(L^+(\lambda)) \equiv V_k^m(x,\lambda)$, $m,k > 0$ as the basic $U-V$ pairs that generate this hierarchy. In this case the role of the dynamical variables is played by the matrix elements of the matrix $L^{(-1)}$.

Let us obtain an explicit form of the simplest equation of the hierarchy described above. For this purpose we have to choose a Hamiltonian that generates the "time" flow in the simplest possible way. We take for such Hamiltonian the function $I_1^2(L^+(\lambda))$, i.e. $t \equiv t_1^{2+}$. In the result we obtain that zero-curvature equation (15) is equivalent the following λ-independent equations:

$$\frac{\partial S}{\partial t} - \frac{\partial M}{\partial x} = [S,M]_A, \tag{19a}$$
$$\frac{\partial S}{\partial x} = [S,M], \tag{19b}$$

where $S \equiv L^{(-1)}$, $M \equiv L^{(-2)} + \big(AL^{(-1)} + L^{(-1)}A\big)$.

In order to obtain equations in partial derivatives for the dynamical variables – matrix elements of the matrix S, it is necessary to solve equation (19b), i.e. to express M via S and S_x and then substitute this expression into equation (19a). We will illustrate this procedure by the simplest, but most interesting example.

Let us now consider the case of the higher-rank algebras. In this case in order to solve equation (19b), i.e. in order to obtain one matrix equation in partial derivatives instead of two equations (19) it is necessary to impose additional constraints on the matrix S. Let $\mathfrak{g} = gl(n)$, $so(2n)$ or $sp(n)$ and for the matrix S to satisfy G-invariant constraint:

$$S^2 = \frac{\alpha}{4}\mathbf{1}. \tag{20}$$

This constraint means that S belongs to the degenerated coadjoint orbits of G of the following type: $Gl(n)/GL(p)\times GL(q)$, $SO(2n)/Gl(n)$ or $SP(n)/GL(n)$. On this orbits we may solve equation (19b) in the following way:

$$M = \frac{1}{\alpha}\left[S, \frac{\partial S}{\partial x}\right] + M', \quad \text{where} \quad M' \in \ker \mathrm{ad}_L.$$

Ambiguity connected with the existence of $\ker \mathrm{ad}_S$ is removed by the requirement that the constraint (20) is consistent with equations (19). It is easy to show, that for $M' = 1/2(AS+SA)$ the constraint (20) is consistent with equation (19), i.e. $\left(\frac{\partial S^2}{\partial x}\right)|_{S^2=\frac{\alpha}{4}\mathbf{1}} = 0$ and $\left(\frac{\partial S^2}{\partial t}\right)_{S^2=\frac{\alpha}{4}\mathbf{1}} = 0$. Resulting matrix equation acquires the following form:

$$\frac{\partial S}{\partial t} = \frac{1}{\alpha}\left[S, \frac{\partial^2 S}{\partial x^2}\right] + \frac{1}{2}\frac{\partial}{\partial x}(AS+SA) + \frac{1}{\alpha}\left[S, \left[S, \frac{\partial S}{\partial x}\right]\right]_A + \frac{1}{2}[S, AS+SA]_A, \tag{21}$$

where $S^2 = \frac{\alpha}{4}\mathbf{1}$. In the case $\alpha = 1$ we obtain equation (3). In the limit $A \to 0$ this equation goes to standard higher-rank generalization of Heisenberg magnet equation [13, 14].

Let us now show, that this equation is direct matrix generalization of the well-known Landau–Lifshitz equation. For this purpose we consider the following example:

Example. Let $\mathfrak{g} = so(4)$. and matrix S satisfy G-invariant constraint (20) with $\alpha = -1$. In this case it is easy to show that matrix S can be written in the form:

$$S = \begin{pmatrix} 0 & -s_3 & s_2 & s_1 \\ s_3 & 0 & -s_1 & s_2 \\ -s_2 & s_1 & 0 & s_3 \\ -s_1 & -s_2 & -s_3 & 0 \end{pmatrix},$$

where three-component vector $\vec{s}$ belongs to $S^2 = SO(3)/SO(2) = SO(4)/GL(2)$:

$$\langle \vec{s}, \vec{s} \rangle = 1/4.$$

As a result of the special form of matrix S the second and third item of the right-hand side of equation (21) are eliminated, and it could be rewritten as equation for the vector $\vec{s}$ as follows:

$$\frac{\partial \vec{s}}{\partial t} = \left[\vec{s} \times \frac{\partial^2 \vec{s}}{\partial x^2} \right] + \left[\vec{s} \times J(\vec{s}) \right].$$

It coincides with the well-known Landau–Lifshiz equation (here $J = 1/4\big(\widehat{A}^2 - 2a_4\widehat{A}\big)$, $\widehat{A} = \mathrm{diag}\,(a_1, a_2, a_3)$).

Generalized Binary Darboux-like Theorem for Constrained Kadomtsev–Petviashvili (cKP) Flows

Yuriy SYDORENKO

Franko Lviv National University, 1 Universytets'ka Str., 79000 Lviv, Ukraine
E-mail: *matmod@franko.lviv.ua*

Generalizations of the classical Darboux theorem are established for pseudo–differential scattering operators of the form $L = \sum_{i=0}^{n} u_i \mathcal{D}^i + \boldsymbol{q}\mathcal{M}\mathcal{D}\boldsymbol{r}^\top$. Iteration of the simplest binary Darboux-like transformations (BDT) leads to a gauge transformed operator with coefficients given by Grammian-type formulas involving a set of eigenfunctions of an operator L and adjoint eigenfunctions (eigenfunctions of the transposed operator L^τ). Nonlinear integrable partial differential equations are associated with the scattering operator L which arise as a symmetry reduction of the matrix KP hierarchy. With a suitable linear time evolution for the eigenfunctions the binary Darboux-like transformation is used to obtain solutions of the integrable equations in terms of Grammian-type determinants.

1 Introduction

Since the mid-1970s, Darboux transformations (DTs) have been shown to be a powerful tool for studying of the nonlinear integrable systems of soliton theory. Darboux's original result [1] is a transformation of the Schrödinger equation $f_{xx} + uf = \lambda f$ with different potentials. With a first eigenfunction for a potential u given, it can be used to map all other eigenfunctions to new eigenfunctions for a Schrödinger operator with a modified potential. Crum [2] considered the iteration of the DT, when a collection of eigenfunctions is given, and Crum's formulae correspond to compact Wronskian representations of the n-soliton solutions of the KdV [3].

Generalizations of these ideas for other spectral equations and their associated soliton systems have been successfully applied to a variety of systems. An excellent overview summarizing various forms of DTs and their applications in soliton theory is the book [3] by Matveev and Salle.

We show that not only differential Lax operators but also pseudo-differential scattering problems may be considered. Our aim is to apply the BDT to Lax operators of the form

$$L = \sum_{i=0}^{n} u_i \mathcal{D}^i + \boldsymbol{q}\mathcal{M}\mathcal{D}^{-1}\boldsymbol{r}^\top \tag{1}$$

(where $\boldsymbol{q} = (q_1, \dots, q_l)$, $\boldsymbol{r} = (r_1, \dots, r_l)$, $\mathcal{M}$ is $(l \times l)$-matrix of constants) and obtain Grammian type solution formulas for the associated nonlinear evolution equations.

Scattering operators of the class (1) were encountered in the context of reductions of the KP hierarchy [4–12], which generalizes a reduction concept originally used to reduce soliton systems in $1 + 1$ dimensions to finite dimensional equations [13–15].

In Section 2 we briefly review the essentials of pseudo-differential symbols to be used for the description of the (constrained) KP hierarchy. We review the fact that for each pair of eigenfunctions φ and adjoint eigenfunctions ψ (eigenfunctions of the transposed operator) the squared eigenfunction can be integrated to a potential $\Omega[\psi, \varphi]$ satisfying $\Omega_x[\psi, \varphi] = \psi^\top \varphi$ and a corresponding time evolution [10, 16]. With these potentials a proper spectral problem can be formulated for pseudo-differential operators of the form (1).

In Section 3 general formulation for the BDT for Lax pairs is presented in terms of pseudo-differential symbols. The resulting Lax pairs are characterized by a gauge operator. Also we show that the BDT will leave the class of operators (1) invariant, if the triggering eigenfunctions are solutions of a spectral problem involving the potential associated with eigenfunctions and adjoint eigenfunctions. This, in combinations with the result on the temporal aspects of the BDTs, provides an efficient tool to generate exact solutions of the nonlinear equations associated with operators of the form (1).

2 The algebra ζ of the pseudo-differential operators. Integrable hierarchies in $2+1$ and $1+1$ dimensions

We consider the algebra

$$\zeta = \left\{ \sum_{i \ll \infty} u_i(x) \mathcal{D}^i \right\}, \tag{2}$$

of pseudo-differential operators of a "space" variable $x \in \mathbb{R}$ with coefficients u_i being (in general case) $(N \times N)$-matrix-valued functions of x. For positive powers $m \in \mathbb{Z}_+$ of the differential operator $\mathcal{D}$, the algebraic multiplication with a multiplication operator represented by a function $u = u(x)$ is given by the usual Leibnitz rule

$$\mathcal{D}^m u := \sum_{j \geq 0} \left(\begin{array}{c} m \\ j \end{array} \right) \frac{\partial^j u}{\partial x^j} \mathcal{D}^{m-j}, \qquad \left(\begin{array}{c} m \\ j \end{array} \right) = \frac{m(m-1)\cdots(m-j+1)}{j!}, \qquad 0! = 1$$

with the same definition for negative powers, so that in particular $\mathcal{D}^{-1} u := \sum\limits_{j \geq 0} (-1)^j u^{(j)} \mathcal{D}^{-1-j}$, we obtain a well defined associative algebraic structure on ζ (2).

The integrable scalar KP hierarchy can be formulated through linear system [14]

$$f_{t_n} = B_n\{f\}, \qquad g_{t_n} = -B_n^\tau\{g\}, \qquad n \in \mathbb{N}, \qquad t_1 := x, \quad t_2 := y, \quad t_3 := t, \quad \ldots \tag{3}$$

with an infinite hierarchy of operators $B_n := (L_{\mathrm{KP}}^n)_+$, where subscript + denotes the projection of the powers of the micro-differential Lax operator

$$L := L_{KP} = \mathcal{D} + \sum_{i \geq 1} U_i \mathcal{D}^{-1} \tag{4}$$

onto its differential part and B_n^τ is a transposed operator. The first of the operators B_n are computed as

$$B_1 = \mathcal{D}, \qquad B_2 = \mathcal{D}^2 + 2U_1, \qquad B_3 = \mathcal{D}^3 + 3U_1\mathcal{D} + 3U_{1x} + U_2.$$

The Lax equation and the implying compatibility conditions of (3) are as follow:

$$L_{t_n} = [B_n, L], \qquad n \in \mathbb{N}, \tag{5}$$

$$B_{n,t_k} - B_{k,t_n} + [B_n, B_k] = 0. \tag{6}$$

They yield the field equations along with differential relations for the fields U_i such as

$$U_2 = -\frac{1}{2} u_x + \frac{1}{2} \partial_x^{-1} u_y,$$

$$U_3 = \frac{1}{4} u_{xx} - \frac{1}{2} u_y - \frac{1}{2} u^2 + \frac{1}{4} \partial_x^{-2} u_{yy}, \qquad \partial_x^{-1} f := \int^x f(s)\, ds,$$

where the leading coefficient $u := U_1$ plays a distinguished role, since it satisfies the KP equation (9) ($n = 2$, $k = 3$ in the (6)) and its higher flows. Consequently all equations of this hierarchy can be expressed via the single field $u := U_1$.

We will refer to solutions of (3) as eigenfunctions and adjoint eigenfunctions respectively.

It has been observed that the product qr of an eigenfunction q and an adjoint eigenfunction r represents a conserved covariant of the KP hierarchy. Hence, one may impose constraints on the KP flows by expressing the dynamical field u via qr [4,5,8,9]. In terms of the Lax operator (4) these constraints are characterized by the requirement that the negative differential orders of a power L^k have the specific form

$$\left(L^k\right)_- = q\mathcal{D}^{-1}r,$$

or, in general,

$$\left(L^k\right)_- = \sum_{i=1}^{m} q_i\mathcal{D}^{-1}r_i := \boldsymbol{q}\mathcal{D}^{-1}\boldsymbol{r}^\top, \tag{7}$$

where m pairs of (adjoint) eigenfunctions are considered [6,7]. For given k this constraint leaves the coefficients $u := U_1, U_2, \dots, U_{k-1}$ in (4) and q_i, r_i, $i = \overline{1,m}$ as independent fields, whereas $U_k, \dots, U_{k+1}, \dots$ become differential expressions of these functions. One may replace L by the new Lax operator

$$L_{k\text{-cKP}} := L^k = \mathcal{D}^k + ku\mathcal{D}^{k-2} + \sum_{i=0}^{k-3} u_i\mathcal{D}^i + \boldsymbol{q}\mathcal{D}^{-1}\boldsymbol{r}^\top, \tag{8}$$

where $u_0, \dots, u_{k-3}$ are differential expressions of $u, U_2, \dots, U_{k-1}$. Thus the fields $u_0, \dots, u_{k-3}, u$ may be regarded as new independent fields related to $u = U_1, U_2, \dots, U_{k-1}$ by a coordinate transformation. The constraints (7) may be regarded as multi-component symmetry reductions of the KP hierarchy (5)–(6), since

$$u_{t_k} = \operatorname{res} L_{t_k} = \operatorname{res}\left[\left(L^k\right)_+, L\right] = \operatorname{res}\left(L^k\right)_x, \qquad \operatorname{res}\left(\sum_{i\ll\infty} a_i\mathcal{D}^i\right) := a_{-1},$$

so that (7) implies the relation [6,7]

$$u_{t_k} = \left(\boldsymbol{q}\boldsymbol{r}^\top\right)_x$$

between the k-th flow of the KP hierarchy and the symmetry generated by square eigenfunctions.

Remark 1. If $\boldsymbol{q} = (q_1, \dots, q_l)$ are eigenfunctions then the product $\boldsymbol{q}\mathcal{M}$ with a constant $(l \times l)$-matrix $\mathcal{M}$ is a vector of the eigenfunctions for KP hierarchy (5)–(6) too.

Remark 2. If we eliminate U_i, $i \geq 2$ from (5), the remaining equations for the function $u := U_1$ in (6) represent the $(2+1)$-dimensional KP equation

$$4u_{t_3} = u_{xxx} + 12uu_x + 3\partial_x^{-1}u_{t_2t_2} \tag{9}$$

and its higher versions.

Remark 3. The so-called "k-constrained KP (k-cKP) hierarchy" (scalar) is the ordinary KP hierarchy (5)–(6) restricted to a pseudo-differential operator $L_{k\text{-cKP}}$ of the form (8)

$$L := L^k = \mathcal{D}^k + \sum_{i=0}^{k-2} u_i\mathcal{D}^i + \boldsymbol{q}\mathcal{D}^{-1}\boldsymbol{r}^\top, \qquad u_{k-2} = ku,$$

$$L_{t_n} = [B_n, L], \qquad B_n := \left(L^{\frac{n}{k}}\right)_+, \qquad n = 2, 3, \dots,$$

where u_i, $\boldsymbol{q}=(q_1,\dots,q_l)$, $\boldsymbol{r}=(r_1,\dots,r_l)$ are all functions of $x:=t_1$ and higher time evolution variables $t_2:=y$, $t_3=t$, ... In particular, the constraints

$$u_x=\left(\boldsymbol{q}\mathcal{M}\boldsymbol{r}^\top\right)_x,\qquad u_y=\left(\boldsymbol{q}\mathcal{M}\boldsymbol{r}^\top\right)_x\qquad\text{and}\qquad u_t=\left(\boldsymbol{q}\mathcal{M}\boldsymbol{r}^\top\right)_x,$$

are known to produce vector versions of $(1+1)$-dimensional of the AKNS ($k=1$), the Yajima–Oikawa ($k=2$) and the Melnikov hierarchy ($k=3$), respectively [6, 7].

3 BDT for the $(N\times N)$-matrix cKP hierarchy

Theorem 1. *Let φ, ψ be $(N\times K)$ matrix solutions of the scattering problem*

$$\sum_{i=0}^{n}u_i\varphi^{(i)}+\boldsymbol{q}\mathcal{M}_0\Omega[\boldsymbol{r},\varphi]:=L\{\varphi\}=\varphi\Lambda,$$

and the transposed scattering problem

$$\sum_{i=0}^{n}(-1)^i\left(u_i^\top\psi\right)^{(i)}-\boldsymbol{r}\mathcal{M}_0^\top\Omega[\boldsymbol{q},\psi]:=L^\tau\{\psi\}=\psi\tilde{\Lambda},$$

where Λ, $\tilde{\Lambda}$ are constant spectral matrices and $\Omega[\boldsymbol{r},\varphi]$, $\Omega[\boldsymbol{q},\psi]$ are functions satisfying $\Omega_x[\boldsymbol{r},\varphi]=\boldsymbol{r}^\top\varphi$, $\Omega_x[\boldsymbol{q},\psi]=\boldsymbol{q}^\top\psi$. Then

1. *Let f be a solution of the spectral problem $\sum\limits_{i=0}^{n}u_if^{(i)}+\boldsymbol{q}\mathcal{M}_0\Omega[\boldsymbol{r},f]:=L\{f\}=f\hat{\Lambda}$ with some constant spectral matrix $\hat{\Lambda}$ and functions $\Omega_x[\boldsymbol{r},f]=\boldsymbol{r}^\top f$.*

Then $F:=W\{f\}=f-\Phi\Omega[\psi,f]$ satisfies the spectral problem

$$\sum_{i=0}^{n}\hat{u}_iF^{(i)}+\Phi\mathcal{M}\Omega[\Psi,F]+\hat{\boldsymbol{q}}\mathcal{M}_0\Omega[\hat{\boldsymbol{r}},F]=F\hat{\Lambda},\tag{10}$$

where $\Omega[\Psi,F]$ and $\Omega[\hat{\boldsymbol{r}},F]$ are functions satisfying $\Omega_x[\Psi,F]=\Psi^\top F$ and $\Omega_x[\hat{\boldsymbol{r}},F]=\hat{\boldsymbol{r}}^\top F$.

2. *The gauge transformed operator $\hat{L}:=WLW^{-1}$ with $W=I-\varphi(C+\Omega[\psi,\varphi])^{-1}\mathcal{D}^{-1}\psi^\top$, where C is a constant $(K\times K)$ matrix, has the form*

$$\hat{L}=\sum_{i=0}^{n}\hat{u}_i\mathcal{D}^i+\Phi\mathcal{M}\mathcal{D}^{-1}\Psi^\top+\hat{\boldsymbol{q}}\mathcal{M}_0\mathcal{D}^{-1}\hat{\boldsymbol{r}}^\top,\tag{11}$$

with $\mathcal{M}=C\Lambda-\tilde{\Lambda}^\top C$, $\Phi=\varphi(C+\Omega[\psi,\varphi])^{-1}$,$\Psi^\top=(C+\Omega[\psi,\varphi])^{-1}\psi^\top$, $\hat{\boldsymbol{q}}=\boldsymbol{q}-\Phi\Omega[\psi,\boldsymbol{q}]$, $\hat{\boldsymbol{r}}=\boldsymbol{r}-\Psi\Omega[\varphi,\boldsymbol{r}]$. The coefficients $\hat{u}_i$, $i=\overline{0,n}$ can be expressed in the form $\hat{u}_n=u_n$, $\hat{u}_i=u_i+P_i(u_{i+1},\dots,u_n,\varphi,\psi)$ with suitable differential expressions P_i of the indicated arguments.

3. *If we have a Lax equation $L_t=[M,L](:=ML-LM)$, $M=\sum\limits_{i=0}^{m}v_i\mathcal{D}^i$ and φ, ψ are solutions of the evolution equations*

$$\varphi_t=M\{\varphi\},\qquad\psi_t=-M^\tau\{\psi\}\tag{12}$$

then BDT triggered by φ and ψ will map any eigenfunction f satisfying both equations

$$f_t=M\{f\},\qquad L\{f\}=f\hat{\Lambda}\tag{13}$$

to a new eigenfunction F for the transformed Lax pair $\hat{L}$ (11), $\hat{M}=-W(\partial_t-M)W^{-1}+\partial_t$, which satisfies both the new evolution equations $F_t=\hat{M}\{F\}$ as well as the new spectral problem $\hat{L}\{F\}=F\hat{\Lambda}$ (10).

Proof. 1. Let $\hat{L} := WLW^{-1}$ and $L\{f\} = f\hat{\Lambda}$ then $F := W\{f\} = f - \Phi\Omega[\boldsymbol{r}, f]$ satisfies

$$\hat{L}\{F\} := WLW^{-1}\{W\{f\}\} = WL\{f\} = W\{f\hat{\Lambda}\} = W\{f\}\hat{\Lambda} = F\hat{\Lambda},$$

and an explicit form of the operator $\hat{L}$ is given in the second part of the Theorem 1.

2. For proving the second part of the Theorem 1 we use helpful formulas

$$1)\ \Psi^\top\Phi = (C + \Omega[\psi,\varphi])^{-1}\psi^\top\varphi(C + \Omega[\psi,\varphi])^{-1} = [(C + \Omega[\psi,\varphi])^{-1}]_x$$
$$\Rightarrow \Omega[\Psi,\Phi] := -(C + \Omega[\psi,\varphi])^{-1}, \tag{14}$$
$$2)\ \Psi^\top F = (C + \Omega[\psi,\varphi])^{-1}\psi^\top[f - \varphi(C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f]] = [(C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f]]_x$$
$$\Rightarrow \Omega[\Psi,F] := -(C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f], \tag{15}$$
$$3)\ (I + \varphi\mathcal{D}^{-1}\Psi^\top)\{F\} := F + \varphi\Omega[\Psi,F] := W\{f\} + \varphi(C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f]$$
$$= f - \Phi\Omega[\psi,f] + \Phi\Omega[\psi,f]] = f$$
$$\Rightarrow W^{-1} = I + \varphi\mathcal{D}^{-1}\Psi^\top := I + \varphi\Omega[\Psi,\cdot] \tag{16}$$

and W^{-1} (16) is the inverse operator to $W = I - \Phi\mathcal{D}^{-1}\psi^\top := I - \Phi\Omega[\psi,\cdot]$.

Analogously to the statement of part 1 of Theorem 1 we prove the next statement.

4) Let g be a solution of the spectral problem $L^\tau\{g\} = g\tilde{\hat{\Lambda}}$ with some constant spectral matrix $\tilde{\hat{\Lambda}}$

$$\sum_{i=0}^{n}(-1)^i\big(u_i^\top g\big)^{(i)} - \boldsymbol{r}\mathcal{M}_0^\top\Omega[\boldsymbol{q},g] = g\tilde{\hat{\Lambda}} \tag{17}$$

and functions $\Omega_x[\boldsymbol{q},g] = \boldsymbol{q}^\top g$.

Then

$$G := W^{-1,\tau}\{g\} = (W^\tau)^{-1}\{g\} = \big(I - \Psi\mathcal{D}^{-1}\varphi^\top\big)\{g\} = g - \Psi\Omega[\varphi,g]$$

satisfies the spectral problem

$$\hat{L^\tau}\{G\} = G\tilde{\hat{\Lambda}}, \qquad \hat{L^\tau} := W^{-1,\tau}L^\tau W^\tau = (\hat{L})^\tau. \tag{18}$$
$$5)\ G^\top F = [g^\top - \Omega[g,\varphi](C + \Omega[\psi,\varphi])^{-1}\psi^\top][f - \varphi(C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f]]$$
$$= g^\top f - g^\top\varphi(C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f] - \Omega[g,\varphi](C + \Omega[\psi,\varphi])^{-1}\psi^\top f$$
$$+ \Omega[g,\varphi](C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f](C + \Omega[\psi,\varphi])^{-1}\psi^\top f$$
$$= [\Omega[g,f] - \Omega[g,\varphi](C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f]]_x$$
$$\Rightarrow \Omega[G,F] := \Omega[g,f] - \Omega[g,\varphi](C + \Omega[\psi,\varphi])^{-1}\Omega[\psi,f]. \tag{19}$$

6) For functions h_i, $i = \overline{1,4}$ and the differential operator $A \in \zeta_+$ next formulas hold (see e.g. [16, 17])

$$Ah_1\mathcal{D}^{-1}h_2 = \big(Ah_1\mathcal{D}^{-1}h_2\big)_+ + A\{h_1\}\mathcal{D}^{-1}h_2, \tag{20}$$
$$h_1\mathcal{D}^{-1}h_2A = \big(h_1\mathcal{D}^{-1}h_2A\big)_+ + h_1\mathcal{D}^{-1}[A^\tau\{h_2\}]^\tau, \tag{21}$$
$$h_1\mathcal{D}^{-1}h_2h_3\mathcal{D}^{-1}h_4 = h_1\Omega[h_2^\top,h_3]\mathcal{D}^{-1}h_4 - h_1\mathcal{D}^{-1}\Omega[h_2^\top,h_3]h_4, \tag{22}$$

and for the operator

$$L = \sum_{i=0}^{n}u_i\mathcal{D}^i + \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top := L_+ + \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top,$$

using formulas (16), (20), (21) by direct calculations we obtain

$$\begin{aligned}
L \to WLW^{-1} &= \big(I - \Phi\mathcal{D}^{-1}\psi^\top\big)\big(L_+ + \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\big)\big(I + \varphi\mathcal{D}^{-1}\Psi^\top\big)\\
&= \big(L - \Phi\mathcal{D}^{-1}\psi^\top L\big)\big(I + \varphi\mathcal{D}^{-1}\Psi^\top\big) = L + L\varphi\mathcal{D}^{-1}\Psi^\top - \Phi\mathcal{D}^{-1}\psi^\top L\\
&- \Phi\mathcal{D}^{-1}\psi^\top L\varphi\mathcal{D}^{-1}\Psi^\top = L_+ + \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top + L_+\varphi\mathcal{D}^{-1}\Psi^\top\\
&+ \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\varphi\mathcal{D}^{-1}\Psi^\top - \Phi\mathcal{D}^{-1}\psi^\top L_+ - \Phi\mathcal{D}^{-1}\psi^\top\boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\\
&- \Phi\mathcal{D}^{-1}\psi^\top L_+\varphi\mathcal{D}^{-1}\Psi^\top - \Phi\mathcal{D}^{-1}\psi^\top\boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\varphi\mathcal{D}^{-1}\Psi^\top\\
&= L_+ + \big(L_+\varphi\mathcal{D}^{-1}\Psi^\top\big)_+ - \big(\Phi\mathcal{D}^{-1}\psi^\top L_+\big)_+ - \big(\Phi\mathcal{D}^{-1}\psi^\top L_+\varphi\mathcal{D}^{-1}\Psi^\top\big)_+\\
&+ \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top + L_+\{\varphi\}\mathcal{D}^{-1}\Psi^\top + \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\varphi\mathcal{D}^{-1}\Psi^\top - \Phi\mathcal{D}^{-1}(L_+^\tau\{\psi\})^\top\\
&- \Phi\mathcal{D}^{-1}\psi^\top\boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top - \big(\Phi\mathcal{D}^{-1}\psi^\top L_+\varphi\mathcal{D}^{-1}\Psi^\top\big)_-\\
&- \Phi\mathcal{D}^{-1}\psi^\top\boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\varphi\mathcal{D}^{-1}\Psi^\top = \hat{L}_+ + \hat{L}_-,
\end{aligned}$$

where

$$\begin{aligned}
\hat{L}_+ &= L_+ + \big(L_+\varphi\mathcal{D}^{-1}\Psi^\top\big)_+ - \big(\Phi\mathcal{D}^{-1}\psi^\top L_+\big)_+ - \big(\Phi\mathcal{D}^{-1}\psi^\top L_+\varphi\mathcal{D}^{-1}\Psi^\top\big)_+\\
&:= L_+ + U_{+1} - U_{+2} - U_{+3} = \sum_{i=0}^{n}\hat{u}_i\mathcal{D}^i, \qquad \hat{u}_n = u_n.
\end{aligned} \tag{23}$$

We obtain the exact form of the differential operators U_{1+}, U_{2+}, U_{3+} after using the Leibnitz rule for a composition of pseudo-differential symbols. These operators are obtained in [16] in explicit forms.

The integral part $\hat{L}_-$ of the operator $\hat{L}$ may be constructed after long transformation using formulas (20)–(22) and the definition of the functions Φ and Ψ.

As a result we obtain

$$\begin{aligned}
\hat{L}_- &= (L\{\varphi\} - \Phi\Omega[\psi, L\{\varphi\}])\mathcal{D}^{-1}\Psi^\top - \Phi\mathcal{D}^{-1}(L^\tau\{\psi\} - \Psi\Omega[\varphi, L^\tau\{\psi\}])^\top + \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top\\
&\quad - \boldsymbol{q}\mathcal{M}_0\mathcal{D}^{-1}(\Psi\Omega[\varphi, \boldsymbol{r}])^\top - \Phi\Omega[\psi, \boldsymbol{q}]\mathcal{M}_0\mathcal{D}^{-1}\boldsymbol{r}^\top + \Phi\Omega[\psi, \boldsymbol{q}]\mathcal{M}_0\mathcal{D}^{-1}(\Psi\Omega[\varphi, \boldsymbol{r}])^\top.
\end{aligned}$$

From the formulas

$$\Omega[\psi, L\{\varphi\}] = \Omega[\psi, \varphi\Lambda] = \Omega[\psi, \varphi]\Lambda, \qquad \Omega[\varphi, L^\tau\{\psi\}] = \Omega[\varphi, \psi\tilde{\Lambda}] = \Omega[\varphi, \psi]\tilde{\Lambda} = (\tilde{\Lambda}^\top\Omega[\varphi, \psi])^\top$$

and the definition of the functions

$$\Phi := \varphi(C + \Omega[\psi, \varphi])^{-1}, \qquad \Psi := \psi\big(C^\top + \Omega[\varphi, \psi]\big)^{-1}$$

it follows

$$\hat{L}_- = \Phi\big(C\Lambda - \tilde{\Lambda}^\top C\big)\mathcal{D}^{-1}\Psi^\top + \big(\boldsymbol{q} - \Phi\Omega[\psi, \boldsymbol{q}]\big)\mathcal{D}^{-1}\big(\boldsymbol{r} - \Psi\Omega[\varphi, \boldsymbol{r}]\big)^\top, \tag{24}$$

thus the gauge transformed operator $\hat{L} := \hat{L}_+ + \hat{L}_-$ (23), (24) has the form (11) and F solves the new spectral problem (10) with the potentials $\Omega[\Psi, F]$ (15) and

$$\Omega[\hat{\boldsymbol{r}}, F] = \Omega[\boldsymbol{r}, f] - \Omega[\hat{\boldsymbol{r}}, \varphi](C + \Omega[\psi, \varphi])^{-1}\Omega[\psi, f], \qquad \Omega_x[\hat{\boldsymbol{r}}, F] = \hat{\boldsymbol{r}}^\top F. \tag{25}$$

Corollary 1. 1. *From formulas* (17)–(18) *we see that function* $G = W^{-1,\tau}\{g\}$ *solves the new adjoint spectral problem*

$$\hat{L^\tau}\{G\} := \sum_{i=0}^{n}(-1)^i\big(\hat{u}_i^\top G\big)^{(i)} - \Psi\mathcal{M}\Omega[\Phi, G] - \hat{\boldsymbol{r}}\mathcal{M}_0\Omega[\hat{\boldsymbol{q}}, G] = G\tilde{\hat{\Lambda}}$$

with the potentials $\Omega[\Phi,G]$, $\Omega[\hat{\boldsymbol{q}},G]$, *which can be calculated similarly to formulas* (14)–(15), (24)*:*

$$\Omega_x[\Phi,G]:=\Phi^{\top}G=\big[\big(C^{\top}+\Omega[\varphi,\psi]\big)^{-1}\Omega[\varphi,g]\big]_x$$
$$\Rightarrow\ \Omega[\Phi,G]=\big(C^{\top}+\Omega[\varphi,\psi]\big)^{-1}\Omega[\varphi,g], \tag{26}$$
$$\Omega[\hat{\boldsymbol{q}},G]=\Omega[\boldsymbol{q},g]-\Omega[\boldsymbol{q},\psi]\big(C^{\top}+\Omega[\varphi,\psi]\big)^{-1}\Omega[\varphi,g]. \tag{27}$$

2. *The functions* F, G *are integrated in the potential* $\Omega[G,F]$ *according to formula* (19).

3. *Let us have a differential operator* $M\in\zeta_+$. *Suppose that equations* (12)–(13) *hold and the adjoint eigenfunction* g *satisfies the linear evolution equation*

$$g_t=-M^{\tau}\{g\}, \tag{28}$$

then F, G *solve the new linear evolution systems*

$$F_t=\hat{M}\{F\},\qquad G_t=-\hat{M}^{\tau}\{G\}, \tag{29}$$

where $\hat{M}=-W(\partial_t-M)W^{-1}+\partial_t=\sum\limits_{i=0}^{m}\hat{v}_i\mathcal{D}^i$.

A proof of this fact and exact formulas for the coefficients $\hat{v}_i$, $i=\overline{0,m-1}$; $\hat{v}_m=v_m$ can be found in [16]. From the compatibility conditions $L_t=[M,L]$, $L_t^{\tau}=[L^{\tau},M^{\tau}]$ for the linear systems $L\{f\}=f\hat{\Lambda}$, $f_t=M\{f\}$ and $L^{\tau}\{g\}=g\tilde{\hat{\Lambda}}$, $g_t=-M^{\tau}\{f\}$ respectively compatibility conditions for the new linear equations (10), (18), (29) follow:

$$\hat{L}_t=[\hat{M},\hat{L}],\qquad \hat{L}_t^{\tau}=[\hat{L}^{\tau},\hat{M}^{\tau}].$$

From the Lagrange formula (see [16]) for the systems (13), (28)

$$(g^{\top}f)_t=\left[\sum_{i=1}^{m}\sum_{j=1}^{i-1}(-1)^j\big(g^{\top}v_i\big)^{(i)}f^{(i-j-1)}\right]_x \tag{30}$$

we obtain a possibility to express all potentials (14), (15), (19), (25), (26), (27) in terms of fixed potential

$$\Omega[g,f]=\int_{(x_0,t_0)}^{(x,t)}P[g,f]\,dx+Q[g,f]\,dt,\qquad \Omega[g,f](x_0,t_0)=0, \tag{31}$$

where $P[g,f]=\Omega_x[g,f]=g^{\top}f$, $Q[g,f]_x=P_t[g,f]$ (see (30)). ■

4 Conclusion remarks

I. In paper [18] a general $(N\times N)$-matrix operator W (16) of the BDT was obtain as a composition of K simplest Darboux-type transformations and K simplest inverse Darboux-type transformations. In this paper it is shown too that the operator W admits a so-called canonical factorization by the K simplest elementary Darboux-like transformations.

II. We used a particular case of the general dressing operator W for integration of the Lax–Zakharov–Shabat equations in a matrix algebra of differential [16] and pseudo-differential (in the scalar case cKP hierarchy, see [17, 19]) operators [20]. This particular case corresponds to a $(K\times K)$-matrix potential function Ω (31) of the form

$$\Omega[\psi,\varphi]=\mathcal{D}^{-1}\big\{\psi^{\top}\varphi\big\}:=C+\int_{\pm\infty}^{x}\psi^{\top}(s,t)\varphi(s,t)\,ds.$$

Wide classes of exact solutions for the integrable systems of the soliton theory in terms of Grammian–type determinants were obtained in these papers.

III. The general BDT Theorem 1 will be applied to constructing the solutions of matrix cKP hierarchy in forthcoming publications.

The formalism of quantization deformation is reviewed and the Weyl–Moyal like deformation is applied to systematic construction of the field and lattice integrable soliton systems from Poisson algebras of dispersionless systems.

1 Introduction

Recently, various aspects of the Moyal deformation theory and its application to the integrable field systems, which leads to the so-called Moyal type Lax dynamics, have become of increasing interest [1–5]. The aim of this paper is to present a complete picture of construction of the field and lattice soliton systems by Weyl–Moyal like deformations from Poisson algebras of underlying dispersionless systems. The Weyl–Moyal like deformation is the special case of the deformation quantization.

In the theory of evolutionary systems (dynamical systems) one of the most important issues is a systematic method for construction of integrable systems. As integrable systems we understand those which have infinite hierarchy of symmetries and conservation laws. It is well known that a very powerful tool, called the classical R-matrix formalism, proved to be very fruitful in systematic construction of the field and lattice soliton systems as well as dispersionless systems (see [6–16] and the references there).

As well known, a quasi-classical limit of field and lattice soliton systems gives related integrable dispersionless systems. We would like to inverse this procedure and construct field and lattice soliton systems from some classes of integrable dispersionless systems through a Weyl–Moyal like deformation quantization procedure. Actually, we will do it at the level of their Lax representations.

2 Classical R-matrix formalism

The crucial point of the formalism is the observation that integrable dynamical systems can be obtained from the Lax equations. Let $\mathfrak{g}$ be a Lie algebra, equipped with the Lie bracket $[\cdot,\cdot]$, for which its dual $\mathfrak{g}^*$ can be identified with $\mathfrak{g}$. So, we assume the existence of a symmetric, non-degenerate and ad-invariant scalar product $(\cdot,\cdot)_{\mathfrak{g}}$. We assume additionally that the scalar product is given by a trace form $\mathrm{tr}:\mathfrak{g}\to\mathbb{R}$, i.e. $(a,b)_{\mathfrak{g}}=\mathrm{tr}\,(ab)$. A linear map $R:\mathfrak{g}\to\mathfrak{g}$, such that the bracket $[a,b]_R:=[Ra,b]+[a,Rb]$ is a second Lie product on $\mathfrak{g}$, is called the classical R-matrix. Then, the vector fields on $\mathfrak{g}$

$$L_{t_n}=[R\,(dC_n)\,,L]\qquad n\in\mathbb{Z}, \tag{1}$$

generated by the differentials of Casimir functions $dC_n\in\mathfrak{g}$, such that

$$[dC_n,L]=0\qquad \forall\, L\in\mathfrak{g},$$

commute mutually. The hierarchy of evolution equations (1) is the Lax hierarchy with common infinite set of symmetries and conserved quantities. In this sense (1) represents a hierarchy of integrable evolution equations. Moreover, it is known that (1) are tri-Hamiltonian systems [17].

To construct the simplest R-structure let us assume that the Lie algebra $\mathfrak{g}$ can be split into a direct sum of Lie subalgebras $\mathfrak{g}_+$ and $\mathfrak{g}_-$, i.e. $\mathfrak{g} = \mathfrak{g}_+ \oplus \mathfrak{g}_-$, where $[\mathfrak{g}_\pm, \mathfrak{g}_\pm] \subset \mathfrak{g}_\pm$. Denoting the projections onto these subalgebras by $P_\pm$, we define the R-matrix as

$$R = \frac{1}{2}(P_+ - P_-) = P_+ - \frac{1}{2} = \frac{1}{2} - P_-. \tag{2}$$

Following the above scheme, we are able to construct in a systematic way integrable Hamiltonian systems, with infinite hierarchy of involutive constants of motion and infinite hierarchy of related commuting symmetries, once we fix a Lie algebra. For example the Lie algebra of pseudo-differential operators with the commutator leads to construction of soliton systems [6–10]. The Lie algebra of shift operators leads to lattice field systems [11, 12]. On the other hand, the Poisson algebras (which are Lie algebras with associative, commutative multiplication) of formal Laurent series lead to the construction of dispersionless systems [13–16].

3 Star products and deformation quantizable Poisson brackets

The idea behind the deformation quantization theory [18–21] is that a classical system can be obtained from quantum system by the quasi-classical limit $\hbar \to 0$, where $\hbar$ is the Planck constant divided by 2π. Therefore, the quantization of classical systems should be done by appropriate deformations depending on a formal parameter $\hbar$.

Let $\mathcal{A} = \mathcal{C}^\infty(M)$ be the space of all smooth ($\mathbb{R}$ or $\mathbb{C}$ valued) functions on $2n$-dimensional smooth manifold M. Let $\{\cdot,\cdot\}_{\rm PB}$ be the classical Poisson bracket, which is bilinear, skew-symmetric and satisfies the Jacobi identity. Obviously $\mathcal{A}$ is a commutative, associative algebra over $\mathbb{R}$ or $\mathbb{C}$ with the standard multiplication. Let $\star$ be the deformed associative non-commutative multiplication on $\mathcal{A}$ given by the following formula

$$f \star g = \sum_{k\geq 0} \hbar^k B_k(f,g), \qquad f, g \in \mathcal{A}, \tag{3}$$

where $\hbar$ is the formal parameter and $B_k : \mathcal{A} \times \mathcal{A} \longrightarrow \mathcal{A}$ are bidifferential (bilinear) operators. We also define deformed bracket as a commutator

$$\{f,g\}_\star := \frac{1}{\hbar}(f \star g - g \star f). \tag{4}$$

Definition 1. An associative deformed multiplication $\star$, given by the formula (3), is a formal quantization of the algebra $\mathcal{A}$ and is called the $\star$-product if

1. $\lim\limits_{\hbar\to 0} f \star g = fg$,
2. $c \star f = f \star c = cf$ for $c \in \mathbb{R}$ or $\mathbb{C}$,
3. $\lim\limits_{\hbar\to 0}\{f,g\}_\star = \{f,g\}_{\rm PB}$.

Lemma 1. *The bracket* (4) *defined by the $\star$-product is bilinear, skew-symmetric and satisfies the Jacobi identity. So, it is well defined Lie bracket.*

The proof is obvious as the Jacobi identity is a consequence of an associativity of multiplication $\star$. Hence, the bracket (4) is called the deformation quantization of the underlying classical Poisson bracket $\{\cdot,\cdot\}_{\rm PB}$. Let $D : \mathcal{A} \longrightarrow \mathcal{A}$ be a linear automorphism parameterized by $\hbar$, such that

$$Df = \sum_{k\geq 0} \hbar^k D_k f, \qquad D_0 = 1, \tag{5}$$

where D_k are differential operators. Such an automorphism produces a new $\star'$-product in $\mathcal{A}$ in the following way

$$f \star' g := D\left(D^{-1}f \star D^{-1}g\right). \tag{6}$$

Definition 2. Two $\star$-products: $\star$ and $\star'$ are called gauge equivalent or simply equivalent if there exist a linear automorphism $D : \mathcal{A} \longrightarrow \mathcal{A}$ (5) such that (6) is satisfied.

Let us consider now a Weyl–Moyal like deformations. It is well known that an arbitrary classical Poisson bracket can be presented in the following form

$$\{f,g\}_{\mathrm{PB}} = f\left(\sum_{i=1}^{n} Y_i \wedge X_i\right) g = f\left(\sum_{i=1}^{n} (Y_i \otimes X_i - X_i \otimes Y_i)\right) g$$
$$= \sum_{i=1}^{n} \left[Y_i(f)X_i(g) - X_i(f)Y_i(g)\right], \tag{7}$$

where X_i, Y_i, $i = 1,\dots,n$ are pair-wise commuting vector fields on $2n$ dimensional smooth manifold M and $f, g \in \mathcal{A}$. The Jacobi identity for (7) follows from the commutativity of vector fields X_i, Y_i. In what follows, we will use the Einstein summation convention in the case of repeating indices i, j at the vectors X, Y and a standard convention (with the summation symbols) otherwise.

Infinitely many Weyl–Moyal like deformed multiplications are of the following form [17]

$$f \star^{\alpha} g = f \exp\left[\frac{\hbar}{2}\left((2-\alpha)\, Y_i \otimes X_i - \alpha X_i \otimes Y_i\right)\right] g. \tag{8}$$

If the classical Poisson bracket (7) is a canonical one, i.e. $Y_i = \partial_{p_i}$, $X_i = \partial_{x_i}$ ($\partial_x = \frac{\partial}{\partial x}$, $\partial_p = \frac{\partial}{\partial p}$), then for $\alpha = 1$ the product (8) is the Groenewold product [22] and the deformed bracket (4) is the well known Moyal bracket [23] and for $\alpha = 0$ the product (8) is the Kupershmidt–Manin (KM) product and the deformed bracket (4) is the KM bracket [24, 25]. Notice that all (8) are well defined quantization deformation of (7). Moreover, they are gauge equivalent by the linear automorphism $D : \mathcal{A} \longrightarrow \mathcal{A}$

$$D^{\alpha} = \exp\left[-\alpha \frac{\hbar}{2} Y_i X_i\right], \qquad \alpha \in \mathbb{R}. \tag{9}$$

Then, $f \star^{\alpha'} g := D^{\alpha'-\alpha}\big(D^{-(\alpha'-\alpha)} f \star^{\alpha} D^{-(\alpha'-\alpha)} g\big)$. Now, we impose the Lie algebra structure on the algebra $\mathcal{A}$, denoting it by $\mathcal{A}_\alpha = (\mathcal{A}, \star^\alpha)$, with the commutator $\{f,g\}_{\star^\alpha} := \frac{1}{\hbar}(f \star^{\alpha} g - g \star^{\alpha} f)$. Obviously, the automorphism (9) induces the isomorphisms between the Lie algebras $D^{\alpha'-\alpha} : \mathcal{A}_\alpha \longrightarrow \mathcal{A}_{\alpha'}$. We will call the Lie algebras $\mathcal{A}_\alpha$ gauge equivalent as one can choose freely the algebra one wants to work with.

4 Poisson algebras of formal Laurent series

Consider the simplest possible case of $\dim M = 2$, when M is parametrized by a pair of coordinates (x,p). The Poisson bracket on $\mathcal{A}$ can be introduced in infinitely many ways as

$$\{f,g\}^r_{\mathrm{PB}} := p^r \left(\frac{\partial f}{\partial p}\frac{\partial g}{\partial x} - \frac{\partial f}{\partial x}\frac{\partial g}{\partial p}\right), \qquad r \in \mathbb{Z}. \tag{10}$$

Moreover, in $\mathcal{A}$ there exists the following Poisson subalgebra of formal Laurent series (Lax polynomials)

$$A = \left\{ L = \sum_{i\in\mathbb{Z}} u_i(x) p^i \right\}, \tag{11}$$

where the coefficients u_i are smooth functions of x. An appropriate non-degenerate symmetric ad-invariant product on A is given by a trace form $\operatorname{Tr} L = \int_\Omega \operatorname{res}_r L \; dx$, where $\operatorname{res}_r L \equiv$

$u_{r-1}(x)$ [15]. We construct the simplest R-matrix, through a decomposition of A into a direct sum of Lie subalgebras. For a fixed r let $A_{\geqslant -r+k} = \{\sum_{i\geqslant -r+k} u_i(x)p^i\}$ and $A_{<-r+k} = \{\sum_{i<-r+k} u_i(x)p^i\}$. As presented in [15], $A_{\geqslant -r+k}, A_{<-r+k}$ are Lie subalgebras in the following cases: $k=0$, $r=0$; $k=1,2$, $r\in\mathbb{Z}$ and $k=3$, $r=2$[1]. Then, the R-matrix (2) is given by $R=\frac{1}{2}(P_{\geqslant -r+k}-P_{<-r+k})$. Hence, the hierarchy of evolution equations (1) for Casimir functionals

$$C_n(L)=\frac{1}{n+1}\operatorname{Tr}\left(L^{n+1}\right), \qquad dC_n(L)=L^n,$$

is given by

$$L_{t_q}=\{(L^q)_{\geqslant -r+k},L\}^r_{\mathrm{PB}}=-\{(L^q)_{<-r+k},L\}^r_{\mathrm{PB}}, \qquad L\in A, \tag{12}$$

which are Lax hierarchies. Notice that (12) are multi-Hamiltonian systems [16]. To construct (1+1)-dimensional dispersionless systems we have to choose properly restricted Lax operators L in such way that L contains the finite number of dynamical fields and gives consistent equations (12). They are given in the form [16]

$$\begin{aligned}
&k=0,\ r=0\ :\quad L=p^N+u_{N-2}p^{N-2}+\cdots+u_1p+u_0,\\
&k=1,\ r\in\mathbb{Z}\ :\quad L=p^N+u_{N-1}p^{N-1}+\cdots+u_{1-m}p^{1-m}+u_{-m}p^{-m},\\
&k=2,\ r\in\mathbb{Z}\ :\quad L=u_Np^N+u_{N-1}p^{N-1}+\cdots+u_{1-m}p^{1-m}+p^{-m}.
\end{aligned} \tag{13}$$

5 Weyl–Moyal like deformation of Poisson algebras of formal Laurent series

The Poisson brackets (10) on $\mathcal{A}$ can be presented in the following form

$$\{f,g\}^r_{\mathrm{PB}}=f\left(p^r\partial_p\wedge\partial_x\right)g, \qquad r\in\mathbb{Z}. \tag{14}$$

Notice that this is a special case of (7), when $Y_1=p^r\partial_p$ and $X_1=\partial_x$ with $[Y_1,X_1]=0$. For a fixed r, the Poisson bracket (14) on $\mathcal{A}$ can be quantized in infinitely many equivalent ways via the $\star^\alpha$-product (8)

$$f\star^\alpha g=f\exp\left[\frac{\hbar}{2}\left((2-\alpha)\,p^r\partial_p\otimes\partial_x-\alpha\partial_x\otimes p^r\partial_p\right)\right]g.$$

One finds that $(p^r\partial_p)^s p^m=c_s^m(r)\ p^{m-s(1-r)}$, $s\in\mathbb{Z}_+$, where for $k\in\mathbb{Z}$

$$c_s^{k(1-r)}(r)=\begin{cases}(1-r)^s\dfrac{k!}{(k-s)!} & \text{for } k\geq s \text{ and } r\neq 1,\\ 0 & \text{for } s>k\geq 0 \text{ and } r\neq 1,\\ (-1+r)^s\dfrac{(s-k-1)!}{s!} & \text{for } k<0 \text{ and } r\neq 1,\end{cases}$$

for $m\neq k(1-r)$: $c_s^m(r)=m(m-(1-r))\cdots(m-(s-1)(1-r))$ and for an arbitrary $m\in\mathbb{Z}$: $c_s^m(1)=m^s$.

We can quantize separately the Poisson subalgebra A (11) to the following Lie subalgebras $A_\alpha=(A,\star^\alpha)\subset\mathcal{A}_\alpha$. Obviously, the Lie algebras A_α for a fixed value of r are gauge equivalent under the isomorphism

$$D^{\alpha'-\alpha}:A_\alpha\longrightarrow A_{\alpha'}, \qquad D^{\alpha'-\alpha}=\exp\left[(\alpha-\alpha')\frac{\hbar}{2}p^r\partial_p\partial_x\right]. \tag{15}$$

[1] In [15–17] there was omitted the case $r=2$, $k=3$, but it does not lead to any new dispersionless systems as it is related to the case $r=0$, $k=0$ by transformation $p\to p^{-1}$. In further considerations we will skip this case.

Let $L = \sum\limits_{m=-\infty}^{+\infty} u_m p^m \in A_\alpha$ and $L' = \sum\limits_{n=-\infty}^{+\infty} v_n p^n \in A_{\alpha'}$. Then $L' = D^{\alpha'-\alpha} L$ and fields u_m, v_n are mutually related in the following way $v_n = \sum_{s\geq 0}((\alpha-\alpha')\frac{\hbar}{2})^s \frac{1}{s!}\ c_s^{s(1-r)+n}(r)\ (u_{s(1-r)+n})_{sx}$.

On the other hand one can show the following relations

$$u \star^\alpha v = uv, \qquad p^m \star^\alpha p^n = p^{m+n}, \tag{16}$$

$$p^m \star^\alpha u = \sum_{s\geq 0} \frac{\hbar^s}{s!} u_{sx} \star^\alpha (p^r \partial_p)^s\, p^m, \qquad u \star^\alpha p^m = \sum_{s\geq 0} \frac{\hbar^s}{s!} (p^r \partial_p)^s\, p^m \star^\alpha u_{sx}. \tag{17}$$

As all relations (16)–(17) have the same form independently of α we skip this index in further considerations. Hence, we can quantize separately the algebra A to the following special algebra of Lax operators:

$$\mathfrak{a} = \left\{ L = \sum_{i\in\mathbb{Z}} u_i(x) \star p^i \right\}. \tag{18}$$

It is obviously associative algebra under commutation rules (17). The algebra $\mathfrak{a}$ in the case of $r = 0$ was considered for the first time in [4]. Then, the Lie-bracket on $\mathfrak{a}$ is given by

$$\begin{aligned} \{u\star p^m, v\star p^n\}_\star &= \frac{1}{\hbar}\left(u\star p^m \star v \star p^n - v\star p^n \star u \star p^m\right) \\ &= \sum_{s=0}^{\infty} \frac{\hbar^{s-1}}{s!}\left[c_s^m(r)\ uv_{sx} - c_s^n(r)\ u_{sx}v\right] \star p^{m+n-s(1-r)}. \end{aligned} \tag{19}$$

Notice that the algebra $\mathfrak{a}$ differs from that defined in the third section, where we introduced deformation quantization, as in (18) we also deformed the Lax polynomials. Let us remark that the algebra $\mathfrak{a}$ is naturally isomorphic to the algebra A_0 as $u \star^0 p^m = up^m$. Hence, in the further considerations we will concentrate only on the algebra $\mathfrak{a}$, as the results for the algebras A_α for all values of α can be obtained simply from A_0. The second reason is that $\mathfrak{a}$ can be considered as the generalization of the algebra of the pseudo-differential operators and the algebra of the shift operators in the following sense. Let us consider the case of $r = 0$, then the rules (17) take the particular form

$$p^m \star u = \sum_{s=0} \hbar^s \binom{m}{s} u_{sx} \star p^{m-s}, \qquad u \star p^m = \sum_{s=0} (-\hbar)^s \binom{m}{s} p^{m-s} \star u_{sx}$$

and the Lie bracket (19) is

$$\{u\star p^m, v\star p^n\} = \sum_{s=0}^{\infty} \hbar^{s-1}\left[\binom{m}{s} uv_{sx} - \binom{n}{s} u_{sx}v\right] \star p^{m+n-s}.$$

Notice, that the algebra $\mathfrak{a}$ for fixed $r = 0$ is isomorphic to the algebra of pseudo-differential operators. In the case of $r = 1$ the rules (17) become

$$\begin{aligned} p^m \star u(x) &= \sum_{s=0} \frac{\hbar^s}{s!} m^s \left(u(x)\right)_{sx} \star p^m = u(x+m\hbar) \star p^m, \\ u(x) \star p^m &= \sum_{s=0} \frac{(-\hbar)^s}{s!} m^s p^m \star \left(u(x)\right)_{sx} = p^m \star u(x-m\hbar), \end{aligned}$$

where we use the formula for Taylor expansion. The Lie bracket (19) is

$$\{u(x)\star p^m, v(x)\star p^n\}_\star = \frac{1}{\hbar}\left[u(x)v(x+m\hbar) - u(x+n\hbar)v(x)\right] \star p^{m+n}.$$

The algebra $\mathfrak{a}$ for a fixed $r = 1$ is isomorphic to the algebra of shift operators.

The following property for $\mathfrak{a}$ is very important.

Lemma 2 ([17]). *An appropriate symmetric, non-degenerate and* ad*-invariant scalar product on* $\mathfrak{a}$ *is given by a trace form* $(L_1, L_2)_{\mathfrak{a}} := \mathrm{Tr}\,(L_1 \star L_2)$*, where* $\mathrm{Tr}\,L = \int_\Omega \mathrm{res}_r L\, dx$ *and* $\mathrm{res}_r L \equiv u_{r-1}(x)$*.*

To proof Lemma 2 one needs the following useful relation: $c_s^m(r) = (-1)^s\, c_s^{(s-1)(1-r)-m}(r)$. Notice that one can simply rewrite the trace formula from $\mathfrak{a} \cong A_0$ to A_α as the trace formula is invariant under isomorphism (15).

6 *R*-matrix formalism and Lax hierarchies for Lie algebra $\mathfrak{a}$

To construct the integrable field systems one has to split the algebra $\mathfrak{a}$ into a direct sum of Lie subalgebras. Observing (19) one finds that in general it can be done only for $r = 0$, $r = 1$ or $r = 2$. Now, we decompose $\mathfrak{a}$ for $r = 0, 1, 2$ into a direct sum of Lie subalgebras in the following way. Let $\mathfrak{a}_{\geqslant -r+k} = \{\sum_{i \geqslant -r+k} u_i(x) \star p^i\}$ and $\mathfrak{a}_{<-r+k} = \{\sum_{i<-r+k} u_i(x) \star p^i\}$. Then, $\mathfrak{a}_{\geqslant -r+k}$ and $\mathfrak{a}_{<-r+k}$ are Lie subalgebras in the case of $r = 0$ for $k = 0, 1, 2$; in the case of $r = 1$ for $k = 1, 2$ and in the case of $r = 2$ for $k = 1, 2, 3$[2]. Hence, the R-matrix (2) is given by $R = \frac{1}{2}(P_{\geqslant -r+k} - P_{<-r+k})$. Then,

The hierarchy of evolution equations are generated by the Casimir functionals

$$C_n(L) = \frac{1}{n+1}\,\mathrm{Tr}\left(L^{n+1}\right), \qquad dC_n(L) = L^n, \qquad L^n = L \star L \star \cdots \star L,$$

and for appropriate k has the form

$$L_{t_n} = \{(L^n)_{\geqslant -r+k}, L\}_\star = -\{(L^q)_{<-r+k}, L\}_\star \tag{20}$$

which are Lax hierarchies. Notice, that (20) are in general tri-Hamiltonian systems [17].

The Lie algebras A_α can be decomposed into direct sum of Lie subalgebras exactly in the same way as $A_0 \cong \mathfrak{a}$. Hence, the R-matrix is invariant under transformations (15). Moreover, as transformations (15) are Lie algebra isomorphisms the Lax hierarchies (20) are also invariant with respect to them.

To construct (1+1)-dimensional closed systems with a finite number of fields we have to choose properly restricted Lax operators L which give consistent Lax equations (20). In the case of $r = 0$ the admissible simplest restricted Lax operators are given in the form

$$\begin{aligned}
&k = 0: \quad L = p^N + u_{N-2} \star p^{N-2} + \cdots + u_1 \star p + u_0,\\
&k = 1: \quad L = p^N + u_{N-1} \star p^{N-1} + \cdots + u_0 + p^{-1} \star u_{-1},\\
&k = 2: \quad L = u_N \star p^N + u_{N-1} \star p^{N-1} + \cdots + u_0 + p^{-1} \star u_{-1} + p^{-2} \star u_{-2}.
\end{aligned} \tag{21}$$

In the case of $r = 1$ the admissible simplest restricted Lax operators are

$$\begin{aligned}
&k = 1: \quad L = p^N + u_{N-1} \star p^{N-1} + \cdots + u_{1-m} \star p^{1-m} + u_{-m} \star p^{-m},\\
&k = 2: \quad L = u_N \star p^N + u_{N-1} \star p^{N-1} + \cdots + u_{1-m} \star p^{1-m} + p^{-m}.
\end{aligned} \tag{22}$$

Comparing the Lax operators related to soliton systems (21) and (22) with the Lax operators related to the dispersionless systems (13) one observes that dispersionless systems for $r \neq 0, 1$ and some for $r = 0$ do not have counterpart soliton systems in the quantization scheme considered.

We will now display examples of some field and lattice soliton systems calculated in proposed quantization scheme. We consider the Lax hierarchy (20) with little changed numerations of

[2] In [17] there was omitted the case $r = 2$, $k = 1, 2, 3$, but it does not lead to any new soliton systems as it is related to the case $r = 0$, $k = 2, 1, 0$, respectively, by transformation $p \to p^{-1}$. In further considerations we will skip the case of $r = 2$.

evolution variables: $L_{t_n} = \left\{\left(L^{\frac{n}{N}}\right)_{\geqslant -r+k}, L\right\}_\star$, where N is the highest order of the Lax operator L. We will exhibit the first nontrivial equation of the Lax hierarchy. The advantage of the use of $\mathfrak{a}$ algebra is that during whole calculations there is no need of using the $\star^\alpha$-product in explicit form and we only use the commutation relations (17). As a result, one gets the same equations and Poisson structures as these obtained from quantized algebra A_0. The Hamiltonian systems related to quantized algebras A_α are simply reconstructed via the linear transformation (15). Such a procedure of calculations is applied in present examples and we have written down only the final results for A_α.

Example 1. The case of $r = 0$ and $k = 0$. The dispersionless Boussinesq system is given in the form

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_2} = \begin{pmatrix} 2v_x \\ -\frac{2}{3}uu_x \end{pmatrix}. \tag{23}$$

It has the following Lax representation [16] $L_{t_2} = \left\{\left(L^{\frac{2}{3}}\right)_{\geqslant 0}, L\right\}^0_{\mathrm{PB}}$ for Lax operator in the form $L = p^3 + up + v \in A$. The quantization procedure leads now to the following Lax operator $L = p^3 + u \star p + v \in \mathfrak{a}$. Then, one can derive the Boussinesq system from $L_{t_2} = \{(L^{\frac{2}{3}})_{\geqslant 0}, L\}_\star$. Now, by the transformation to the algebras A_α one finds the following systems

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_2} = \begin{pmatrix} 2v_x + (\alpha - 1)\,\hbar u_{2x} \\ -\frac{2}{3}uu_x + (1-\alpha)\,\hbar v_{2x} - \left(\frac{\alpha^2}{2} - \alpha + \frac{2}{3}\right)\hbar^2 u_{3x} \end{pmatrix}. \tag{24}$$

In the case of $\alpha = 0$ (24) is obviously the standard case of Boussinesq system obtained from Gel'fand–Dikii hierarchy, for $\alpha = 1$ it is the Moyal case. The limit $\hbar \to 0$ of (24) gives (23) as it should be.

Example 2. The case of $r = 1$ and $k = 1$. The dispersionless Toda system has the form

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_2} = \begin{pmatrix} v_x \\ u_x v \end{pmatrix}. \tag{25}$$

The Lax representation for (25) is [16] $L_{t_2} = \{(L^2)_{\geqslant 0}, L\}^1_{\mathrm{PB}}$, where the Lax operator is $L = p + u + vp^{-1}$. Then, the quantization scheme leads to the following Lax operator in $\mathfrak{a}$ in the form $L = p + u(x) + v(x) \star p^{-1}$. One derives the Toda system from $L_{t_2} = \{(L^2)_{\geqslant 0}, L\}_\star$. Next, by the transformation to A_α one finds

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_2} = \frac{1}{\hbar}\begin{pmatrix} v\left(x + \left(1 - \frac{\alpha}{2}\right)\hbar\right) - v\left(x - \frac{\alpha}{2}\hbar\right) \\ v(x)\left[u\left(x + \frac{\alpha}{2}\hbar\right) - u\left(x - \left(1 - \frac{\alpha}{2}\right)\hbar\right)\right] \end{pmatrix}. \tag{26}$$

The case of $\alpha = 0$ of (26) is the standard case of Toda system, the case of $\alpha = 1$ is the Moyal case. Notice that in our construction Toda equation depends on continuous coordinate x contrary to a standard case when x is integer.

7 Conclusions

In a previous paper [16] we have constructed Lax representations for a wide class of dispersionless systems, derived from classical R-matrix theory. The number of the constructed dispersionless systems is much greater then the number of known soliton systems (dispersive integrable systems). So, the question rises whether for any dispersionless Lax hierarchy one can construct a related soliton hierarchy. We have tried to obtain an answer to this question via the procedure

of deformation quantization for Poisson algebras of dispersionless systems and appropriate R-matrix theory. We have managed to quantize all Poisson algebras (with arbitrary r (10)) but the R-matrix after quantization, at least of the form (2), exists only in the case of two algebras, i.e. for $r = 0$ ($r = 2$) and $r = 1$, respectively. The first case leads to soliton field systems related to the algebra of pseudo-differential operators, and the second one leads to lattice soliton systems related to the algebra of shift operators. In that sense, although we have failed to construct new soliton equations through presented deformation procedure, nevertheless we have found a unified procedure of the construction of field and lattice Hamiltonian soliton systems in one scheme.

Relation between Periodic Soliton Resonance and Instability

Masayoshi TAJIRI

Graduate School of Engineering, Osaka Prefecture University, Sakai, Osaka, 599-8531, Japan
E-mail: *tajiri@ms.osakafu-u.ac.jp*

There are periodic soliton resonances in interactions between two periodic solitons and between periodic soliton and another kind of soliton. A close relation exists between the periodic soliton resonance and soliton instability to transverse disturbances. It is shown that the instability occurred in the line soliton is relaxed by emission of the periodic soliton and the periodic soliton resonance is inverse process of the instability.

1 Introduction

The dynamics of nonlinear waves in higher-dimensional space have richer phenomena than one-dimensional case, since various localized structures may be considered as candidates for solitons. The two-dimensional generalization of the Korteweg–de Vries (KdV) equation was given by Kadomtsev and Petviashvili to discuss the stability of one-dimensional KdV soliton (line soliton in two dimensions) against transverse long-wave disturbances, which is known as the Kadomtsev–Petviashvili (KP) equation and is expressed as follows [1],

$$(u_t + 6uu_x + u_{xxx})_x + 3su_{yy} = 0, \qquad s = \pm 1. \tag{1}$$

The propagation property of solitons depends essentially on the sign of s in equation (1). In the media with negative dispersion ($s = +1$), line solitons are stable to long transverse perturbations. On the other hand, line solitons are unstable for positive dispersion ($s = -1$) [1]. This leads to the conjecture that solutions having two-dimensional localized structures should be found in the positive dispersion case. Such solitons were found by Manakov *et al.* [2] and Ablowitz and Satsuma [3], which have no longer exponential tails, but instead take the form of rational functions in both space and time variables.

The N line soliton solution was obtained by Zakharov and Shabat [4] and Satsuma [5]. Miles [6] found the existence of the singular parameter regime for multi-soliton solutions in the negative dispersion case, where the solutions become singular. He showed that the two-soliton solution reveal a resonant interaction when it is just on the borderline between regular and singular regimes in the parameter space. In this case, when the relative inclination between wave normals is at a certain small critical angle, two solitons interact strongly to make a resonant soliton from a point at which two incident solitons meet together. Such a resonant interaction is called "soliton resonance". On the other hand, in the positive dispersion media, the solution which describes the interaction between two line solitons never satisfies the resonant condition.

Another kind of two-dimensional localized soliton in the positive dispersion media is a periodic soliton, which was found by Zaitsev at first by superposition of rational solitons (algebraic solitons) [7]. The periodic soliton solutions which describe the multi-soliton interactions have been obtained by Tajiri and Murakami [8]. The stability for the y-periodic and x-periodic solitons has been discussed by Zhdanov [9], using the dressing method. He also obtained the solution which describes the nonlinear stage of instability of the line soliton propagating in the x-direction and pointed out the decay of a one-dimensional soliton into a soliton of lower amplitude and a periodic soliton.

As there are three kinds of solitons, line soliton, algebraic soliton and periodic soliton, various interactions between two different kinds of solitons may happen in the positive dispersion media. The interactions between two periodic solitons, periodic soliton and line soliton, line soliton and algebraic soliton and periodic soliton and algebraic soliton have been studied by several authors [10–16]. Thing to be most emphasized among them is the existence of resonant interactions between two periodic solitons and between periodic soliton and another kind of soliton. Here we call them "periodic soliton resonances", which are qualitatively different from the resonant interaction between two line solitons (soliton resonances) of the KP equation with negative dispersion. Periodic soliton resonances are irrelevant to the divergence of soliton solutions. This is crucially different from the case of soliton resonances.

Another equation having two-dimensional localized soliton solutions is the Davey–Stewartson (DS) equation [17]:

$$\begin{aligned} &iu_t + pu_{xx} + u_{yy} + r|u|^2u - 2uv = 0, \\ &v_{xx} - pv_{yy} - r\left(|u|^2\right)_{xx} = 0, \end{aligned} \tag{2}$$

where $p = \pm 1$, r is constant. This is the two-dimensional generalization of the nonlinear Schrödinger (NLS) equation. Equation (2) with $p = +1$ and $p = -1$ are called the DSI and DSII equations, respectively. Anker and Freeman [18] studied the interactions between two dark line solitons which are skewed with respect to each other and found the existence of soliton resonances. The DS equation has algebraic soliton and periodic soliton solutions in addition to the dark line soliton solution [19]. In the previous paper, the interactions between two periodic solitons, between dark line soliton and periodic soliton, and between algebraic soliton and periodic soliton were investigated [20, 21]. We found the existence of periodic soliton resonances in each case.

The existence of solitons having the structures peculiar to high-dimensionality may contribute to the variety of the dynamics of nonlinear waves. Especially, we expect that the periodic soliton resonances play fundamental role in the nonlinear development of high-dimensional wave fields as the existence of periodic solitons is related to the instability of solitons.

The purpose of this study is to show that we can discuss the problem of the stability of solitons by making use of the solutions of periodic soliton resonance.

2 Soliton stability theory due to periodic soliton resonance solutions

2.1 Stability of the line soliton of the KP equation with positive dispersion

At first, we consider the resonant interaction between line soliton and y-periodic soliton which propagate in the same direction. Although we can obtain the expressions that describe the general interaction between solitons in arbitrary directions, we limit our concern into the solitons that extend in the y-direction and propagate in the x-direction. The solutions that describe the interaction between line soliton and y-periodic soliton are given by [13]

$$u = 2(\log f)_{xx}, \tag{3}$$

with

$$f = 1 - \mathrm{e}^{\xi_P}\cos\eta + \frac{M}{4}\mathrm{e}^{2\xi_P} + \mathrm{e}^{\xi_L}\left(1 - N\mathrm{e}^{\xi_P}\cos\eta + \frac{MN^2}{4}\mathrm{e}^{2\xi_P}\right), \tag{4}$$

where

$$\xi_P = \alpha x - \Omega_P t + \sigma_P, \qquad \xi_L = Px - \Omega_L t + \sigma_L, \qquad \eta = \delta y + \theta,$$

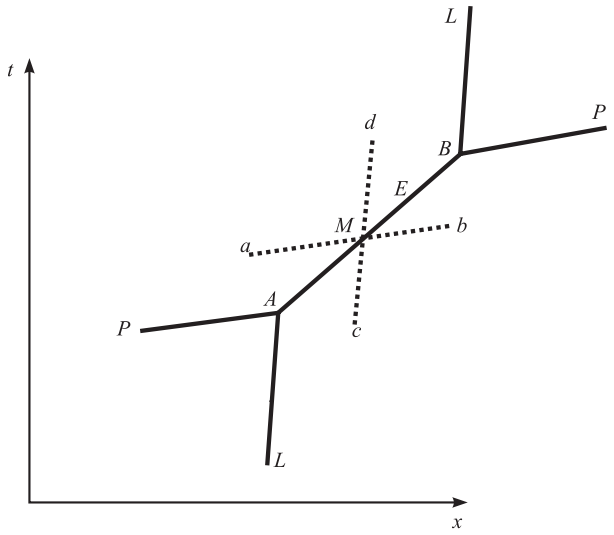

Figure 1. The schematic diagram of the world line of the soliton humps in the $x-t$ plane. AB corresponds to the quasi-resonant state. On line ab; $\xi_P + (1/2)\Gamma \simeq O(1)$ and on line cd; $\xi_L + \Gamma \simeq O(1)$.

$$\Omega_P = \alpha^3 + 3\frac{\delta^2}{\alpha}, \qquad \Omega_L = P^3, \qquad M = \frac{\delta^2}{\delta^2 - \alpha^4}, \qquad N = \frac{(\alpha - P)^2 - (\delta/\alpha)^2}{(\alpha + P)^2 - (\delta/\alpha)^2}, \tag{5}$$

where σ_P, σ_L and θ arbitrary real constants. The phase shift due to the interaction between line soliton and y-periodic soliton is determined only by N. In the case $\alpha P > 0$, the phase shift in the propagating direction is given by $\Gamma = \log|N|$ while that in the transverse direction is determined by the sign of N.

The resonant conditions are obtained by equating the denominator of N to zero as follows,

$$\frac{\delta}{\alpha^2} = \frac{P}{\alpha} + 1, \tag{6}$$

$$\frac{\delta}{\alpha^2} = -\frac{P}{\alpha} - 1. \tag{7}$$

Fig. 1 is the schematic diagram of the world lines of the soliton humps in the $x-t$ plane for the attractive interaction ($\Gamma > 0$). The line AB in Fig. 1 corresponds to the quasi-resonant state and at the midpoint M of the world line AB, the quasi-resonant state reaches the most resonant state. When we replace $\xi_P + \frac{1}{2}\ln|N|$ and $\xi_L + \ln|N|$ with $\tilde{\xi}_P$ and $\tilde{\xi}_L$, respectively, so as to $\tilde{\xi}_P \sim \tilde{\xi}_L \sim O(1)$ at the most resonant point M, that is,

$$\xi_P + \frac{1}{2}\log|N| = \tilde{\xi}_P \sim O(1), \qquad \sigma_P + \frac{1}{2}\log|N| = \tilde{\sigma}_P,$$
$$\xi_L + \log|N| = \tilde{\xi}_L \sim O(1), \qquad \sigma_L + \log|N| = \tilde{\sigma}_L,$$

(see Fig. 1) equation (4) is rewritten as follows;

$$f = f^{(0)} + \frac{1}{\sqrt{|N|}} f^{(1)} + \frac{1}{|N|} f^{(2)}, \tag{8}$$

with

$$f^{(0)} = 1 + \frac{M}{4} \mathrm{e}^{\tilde{\xi_L} + 2\tilde{\xi_P}}, \tag{9}$$

$$f^{(1)} = -\mathrm{e}^{\tilde{\xi_P}} \left\{ \cos\eta + \mathrm{e}^{\tilde{\xi_L}} \cos(\eta + \epsilon\pi) \right\}, \tag{10}$$

$$f^{(2)} = \mathrm{e}^{\tilde{\xi}_L} + \frac{M}{4}\mathrm{e}^{2\tilde{\xi}_P}, \tag{11}$$

where $\epsilon = 0$ for $N > 0$ and $\epsilon = 1$ for $N < 0$. Taking the limit $|N| \to \infty$, we see that the resonant soliton is the line soliton with wave number $(P/2 + \alpha)$. If we take $|N| \gg 1$, equation (8) shows that the quasi-resonant state consists of the resonant line soliton and small disturbance. The disturbance becomes minimum at midpoint M. The line ME in Fig. 1 corresponds to the period of the linear development of the disturbance on the resonant line soliton. Substituting equation (8) into $u = 2(\log f)_{xx}$, and neglecting the terms of $O(1/|N|)$, we have

$$u = u^{(0)} + \frac{1}{\sqrt{|N|}}\left\{-2u^{(0)}\frac{f^{(1)}}{f^{(0)}} + \frac{2}{f^{(0)2}}\left(f^{(0)}_{xx}f^{(1)} + f^{(0)}f^{(1)}_{xx} - 2f^{(0)}_{x}f^{(1)}_{x}\right)\right\}, \tag{12}$$

where

$$u^{(0)} = \frac{1}{2}P_0^2\,\mathrm{sech}^2\frac{1}{2}\left(P_0 x - \Omega_0 t + \sigma_0\right),$$

which is resonant line soliton solution, where $\sigma_0 = 2\tilde{\sigma}_P + \tilde{\sigma}_L + \log\left(\frac{M}{4}\right)$. Substituting equations (9) and (10) into equation (12) and replacing $\tilde{\xi}_L$ with

$$\tilde{\xi}_L = \frac{P}{P_0}\xi_0 + \left(\frac{P}{P_0}\Omega_0 - \Omega_L\right)t - \frac{P}{P_0}\sigma_0 + \tilde{\sigma}_L, \tag{13}$$

we have [22]

$$\begin{aligned} u = u^{(0)} + \frac{u^{(0)}}{\sqrt{MN_L}}\Bigg[&\left\{2\,\mathrm{sech}\frac{\xi_0}{2} - \frac{4\alpha\,(\alpha+P)}{P_0^2}\left(A\cosh\frac{1}{2}\xi_0 - B\sinh\frac{1}{2}\xi_0\right)\right\} \\ &\times \exp\left(\frac{P}{2P_0}\xi_0 + \frac{1}{2}\left(-\frac{P}{P_0}\sigma_0 + \tilde{\sigma}_L\right)\right)\mathrm{e}^{\gamma t} \\ &+ \left\{2\,\mathrm{sech}\frac{\xi_0}{2} - \frac{4\alpha\,(\alpha+P)}{P_0^2}\left(A\cosh\frac{1}{2}\xi_0 + B\sinh\frac{1}{2}\xi_0\right)\right\} \\ &\times \exp\left(-\left\{\frac{P}{2P_0}\xi_0 + \frac{1}{2}\left(-\frac{P}{P_0}\sigma_0 + \tilde{\sigma}_L\right)\right\}\right)\mathrm{e}^{-\gamma t}\Bigg]\cos\eta, \end{aligned} \tag{14}$$

where

$$\gamma = \frac{1}{2}\left(\frac{P}{P_0}\Omega_0 - \Omega_L\right). \tag{15}$$

Substituting the relation $P{=}P_0{-}2\alpha$ into the resonant condition, $\alpha + P - (\delta/\alpha) = 0$, we have

$$\alpha = \frac{1}{2}\left(P_0 - \sqrt{P_0^2 - 4\delta}\right), \tag{16}$$

$$P = \sqrt{P_0^2 - 4\delta}. \tag{17}$$

When we substitute equations (16) and (17) into the dispersion relations of line soliton and y-periodic soliton, Ω_P and Ω_L can be expressed by P_0 and δ. Then we have the growth rate γ,

$$\gamma = 2\delta\sqrt{P_0^2 - 4\delta}, \tag{18}$$

which is the same as the result obtained by Zhdanov by using the dressing method [9]. Taking the long limit $|\delta| \ll 1$ $(\alpha \ll 1)$, we have

$$\alpha \simeq \frac{\delta}{P_0}, \qquad \frac{4\alpha(\alpha+P)}{P_0^2}A \simeq \frac{4\alpha(\alpha+P)}{P_0^2}B \simeq 2\left(1 - \frac{2\delta}{P_0^2}\right),$$

and then

$$\gamma \simeq 2\delta P_0, \tag{19}$$

$$\begin{aligned} u \simeq u^{(0)} &- \frac{2}{\sqrt{MN_L}}\frac{1}{P_0}\left[C\left\{-\frac{P_0^3}{2}\operatorname{sech}^2\left(\frac{1}{2}\xi_0\right)\tanh\left(\frac{1}{2}\xi_0\right)\right.\right. \\ &- \frac{\gamma}{2}\left(\operatorname{sech}^2\left(\frac{1}{2}\xi_0\right) - \frac{\xi_0}{2}\operatorname{sech}^2\left(\frac{1}{2}\xi_0\right)\tanh\left(\frac{1}{2}\xi_0\right)\right)\Big\}\mathrm{e}^{\gamma t} \\ &- \frac{1}{C}\left\{-\frac{P_0^3}{2}\operatorname{sech}^2\left(\frac{1}{2}\xi_0\right)\tanh\left(\frac{1}{2}\xi_0\right) - \left(\frac{-\gamma}{2}\right)\left(\operatorname{sech}^2\left(\frac{1}{2}\xi_0\right)\right.\right. \\ &\left.\left.\left. - \frac{\xi_0}{2}\operatorname{sech}^2\left(\frac{1}{2}\xi_0\right)\tanh\left(\frac{1}{2}\xi_0\right)\right)\right\}\mathrm{e}^{-\gamma t}\right]\cos\eta, \end{aligned} \tag{20}$$

where $C = \exp\left\{-(1/2)\left(\sqrt{P_0^2 - 4\delta}\sigma_0/P_0 - \tilde{\sigma}_L\right)\right\}$. It is very interesting to note that these equations are expressed only by the wave number of resonant line soliton, P_0, and the wave number of the disturbance δ. We can see that the solution (20) has the growing term and decaying term.

2.2 Stability of the line soliton of the DSI equation

In this section, the stability of the line soliton to the DSI equation is studied by making use of the solution of periodic soliton resonance. The solution describing the interaction between line soliton and y-periodic soliton is given by

$$u = u_0 e^{i\zeta}\frac{g}{f}, \qquad v = -2\left(\ln f\right)_{xx} \tag{21}$$

with

$$f(\xi_P, \xi_L) = 1 + e^{\xi_P}\cos\eta + \frac{M}{4}e^{2\xi_P} + e^{\xi_L}\left\{1 + Ne^{\xi_P}\cos\eta + \frac{MN^2}{4}e^{2\xi_P}\right\}, \tag{22}$$

$$g(\xi_P, \xi_L, \phi_P, \phi_L) = f(\xi_P + i\phi_P, \xi_L + i\phi_L), \tag{23}$$

where

$$\begin{aligned} &\zeta = kx + ly - \omega t, \qquad \xi_P = \alpha x - \Omega_P t + \sigma_P, \\ &\xi_L = Px - \Omega_L t + \sigma_L, \qquad \eta = \delta y - \gamma_P t + \theta, \\ &\sin^2(\phi_P/2) = (\alpha^2 + \delta^2)/(2ru_0^2), \qquad \sin^2(\phi_L)/2) = P^2/(2ru_0^2), \\ &\Omega_P = 2k\alpha - (\alpha^2 - \delta^2)\cot(\phi_P/2), \qquad \gamma_P = 2l\delta, \\ &\Omega_L = P\{2k - P\cot(\phi_L/2)\}, \qquad M = \{1 - (\alpha^2 + \delta^2)^2/(2\delta^2 ru_0^2)\}^{-1}, \\ &N = \frac{2ru_0^2\sin(\phi_P/2)\sin(\phi_L/2)\cos\{(\phi_P - \phi_L)/2\} - \alpha P}{2ru_0^2\sin(\phi_P/2)\sin(\phi_L/2)\cos\{(\phi_P + \phi_L)/2\} - \alpha P}. \end{aligned} \tag{24}$$

When we replace $\xi_P + \frac{1}{2}\ln|N|$ and $\xi_L + \ln|N|$ with $\tilde{\xi}_P$ and $\tilde{\xi}_L$, respectively, so as to $\tilde{\xi}_P \sim \tilde{\xi}_L \sim O(1)$ at the most resonant point M, equations (22) and (23) are rewritten as follows [23]:

$$\begin{aligned} f &= f^{(0)} + \frac{1}{\sqrt{|N|}}f^{(1)}\cos\eta + \frac{1}{|N|}f^{(2)}, \\ g &= g^{(0)} + \frac{1}{\sqrt{|N|}}g^{(1)}\cos\eta + \frac{1}{|N|}g^{(2)}, \end{aligned} \tag{25}$$

where

$$f^{(0)} = 1 + \frac{M}{4}\exp(\tilde{\xi}_0), \tag{26}$$

$$g^{(0)} = 1 + \frac{M}{4}\exp(\tilde{\xi}_0 + \mathrm{i}\Phi), \tag{27}$$

$$f^{(1)}(\tilde{\xi}_P, \tilde{\xi}_L) = \exp(\tilde{\xi}_P)\left\{1 + \varepsilon\exp(\tilde{\xi}_L)\right\}, \tag{28}$$

$$f^{(2)}(\tilde{\xi}_P, \tilde{\xi}_L) = \exp(\tilde{\xi}_L) + \frac{M}{4}\exp(2\tilde{\xi}_P), \tag{29}$$

$$g^{(j)} = f^{(j)}(\tilde{\xi}_P + \mathrm{i}\phi_P, \tilde{\xi}_L + \mathrm{i}\phi_L) \qquad (j = 1, 2), \tag{30}$$

where $\Phi = 2\phi_P + \phi_L$, $P_0 = 2\alpha + P$, $\Omega_0 = 2\Omega_P + \Omega_L$, $\tilde{\xi_0} = 2\tilde{\xi}_P + \tilde{\xi}_L = P_0 x - \Omega_0 t + 2\tilde{\sigma}_P + \tilde{\sigma}_L$ and $\varepsilon = 1$ for $0 < N$, $\varepsilon = -1$ for $N < 0$. Taking the limit $|N| \to \infty$, we have the resonant line soliton solution with wave number P_0 and phase Φ as follows,

$$u_0 = u_0 \mathrm{e}^{\mathrm{i}\zeta}\frac{1 + \mathrm{e}^{\xi_0 + \mathrm{i}\Phi}}{1 + \mathrm{e}^{\xi_0}}, \qquad v_0 = -\frac{P_0^2}{2}\mathrm{sech}^2\frac{1}{2}\xi_0, \tag{31}$$

where $\xi_0 = \tilde{\xi}_0 + (1/2)\log(M/4)$. Using the resonant condition, and dispersion relations of y-periodic soliton and line soliton, we obtain

$$P^2 = P_0^2 - 4\delta^2 \pm 4\left(\sqrt{2ru_0^2 - P_0^2}\right)\delta. \tag{32}$$

Taking account of the relations, $\alpha = (P_0 - P)/2$, $\sin^2(\phi_L/2) = P^2/2ru_0^2$ and $\phi_P = (\Phi - \phi_L)/2$, we see that P, α, ϕ_L, ϕ_P, Ω_P and Ω_L are expressed by P_0, Φ and δ. Therefore, the quasi-resonant solution is expressed by parameters (P_0, Φ, δ), which are the wave number and the phase of resonant line soliton and the wave number of transverse disturbance on the resonant line soliton, respectively. Neglecting the terms of $O(1/N)$, we have [23].

$$u = u_0 \mathrm{e}^{\mathrm{i}\zeta}\left[\frac{g^{(0)}}{f^{(0)}} + \frac{1}{\sqrt{|N|}}\frac{g^{(0)}}{f^{(0)}}\left(\frac{g^{(1)}}{g^{(0)}} - \frac{f^{(1)}}{f^{(0)}}\right)\cos\eta\right], \tag{33}$$

$$v = -2\frac{f_{xx}^{(0)}f^{(0)} - f_x^{(0)^2}}{f^{(0)^2}} + \frac{1}{\sqrt{|N|}}\left[\left\{4\frac{f_{xx}^{(0)}f^{(0)} - f_x^{(0)^2}}{f^{(0)^2}}\frac{f^{(1)}}{f^{(0)}} - \frac{2}{f^{(0)^2}}\left[f_{xx}^{(0)}f^{(1)} - 2f_x^{(0)}f_x^{(1)} + f^{(0)}f_{xx}^{(1)}\right]\right\}\cos\eta\right]. \tag{34}$$

It should be noted that the magnitude of the initial disturbance (the magnitude of the disturbance on the resonant line soliton at the most resonant state) is of the order $(1/\sqrt{|N|})$. The second term of equations (33) and (34) describes the linear development of the disturbance on the resonant line soliton. Regarding the quasi-resonant soliton solution at the most resonant state as the initial state, we can size the full-time evolution up to the nonlinear stage of the soliton with a small disturbance undergoing the instability by using the quasi-resonant solution. From these facts, we can expect that the instability occurred in the line soliton is relaxed by the emission of the periodic soliton and the periodic soliton resonance is inverse process of the instability.

The Connection of the Degasperis–Procesi Equation with the Vakhnenko Equation

Vyacheslav O. VAKHNENKO † *and John PARKES* ‡

Travelling-wave solutions of the Degasperis–Procesi equation (DPE) are investigated. The solutions are characterized by two parameters. Hump-like, loop-like and coshoidal periodic-wave solutions are found; hump-like, loop-like and peakon solitary-wave solutions are obtained as well. Hone and Wang showed a connection between the DPE and the Vakhnenko equation (VE). Comparing the solutions of the DPE and the VE, we observe that, for both equations at interaction of waves, there are three kinds of phaseshift that depend on the ratio of wave amplitudes. In particular, there is a case when two interacted waves have phaseshifts in the positive direction.

1 Introduction

This report deals with the Degasperis–Procesi equation (DPE) [1–3]

$$u_t - u_{txx} + 4uu_x = 3u_xu_{xx} + uu_{xxx} \tag{1}$$

which is contained in the family of equations [1]

$$u_t - u_{txx} + (b+1)uu_x = bu_xu_{xx} + uu_{xxx}, \tag{2}$$

(parameter b is constant). When $b = 2$, equation (2) reduces to the well-known Cammasa–Holm equation (CH) [4, 5]

$$u_t - u_{txx} + 3uu_x = 2u_xu_{xx} + uu_{xxx}. \tag{3}$$

Mikhailov and Novikov developed a powerful extension of the symmetry classification method [6], and applying this to the equation (2) they found that only the cases $b = 2$, 3 could possess infinitely many commuting symmetries, and so only these two cases are integrable. In a recent paper Degasperis, Holm and Hone [2] constructed a Lax pair of the equation (1), and hence proved the integrability of the Degasperis–Procesi equation. Unfortunately, there are no solutions of the direct problem and the inverse problem of the spectral equation from this Lax pair.

Hone and Wang [7] have shown the connection of the DPE (1) with the integrable Vakhnenko equation (VE) [8–10]

$$(u_t + uu_x)_x + u = 0. \tag{4}$$

Indeed, the transformation $x \to \varepsilon x - t/3\varepsilon$, $t \to \varepsilon t$, $u \to u - 1/3\varepsilon^2$ reduces the DPE to the VE when $\varepsilon \to 0$

$$[(u_t + uu_x)_x + u]_x = \varepsilon^2(u_t + 4uu_x). \tag{5}$$

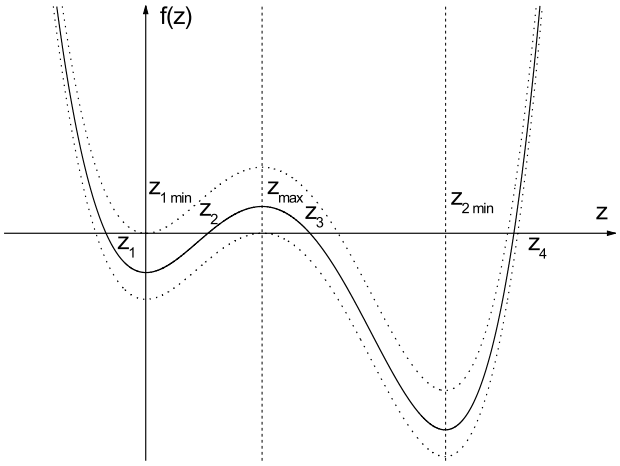

Figure 1. The polynomial $f(z)$. The interval of integration is between the roots z_2 and z_3.

Recently, we have investigated equation (4) by direct integration [8,9], by Hirota's method [11] as well as by the inverse scattering transform method [10]. In the context of this paper, it is of interest that the VE has two families of travelling-wave solutions (see Figs. 1, 2 in [8]); in particular, there is a soliton solution in loop-like form.

Comparing the properties of the solutions of the DPE (1) and the VE (4), we observe that for both equations under interaction of waves, there are three kinds of phaseshift that depend on the ratio of wave amplitudes [2, 12, 13]. In particular, there is a case when two interacted waves have phaseshifts in the positive direction.

However, it engages our attention that soliton solutions have not been observed for the DPE recently. If the VE has a loop-like solution, it follows that the DPE should admit a loop-like solution. In this paper we investigate the travelling-wave solutions of the DPE. The solutions are characterized by two parameters. Hump-like, loop-like and coshoidal periodic-wave solutions are found; hump-like, loop-like and peakon solitary-wave solutions are obtained as well.

2 Travelling-wave solutions

We consider the DPE (1). Restricting our attention to travelling waves, we introduce new variables

$$z = (u - v)/|v|, \qquad \eta = x - vt - x_0, \qquad \tau = |v|t, \tag{6}$$

where v and x_0 are arbitrary constants with $v \neq 0$. In this case the initial equation is reduced to the ODE

$$(zz_\eta)_{\eta\eta} = (4z + 3c)z_\eta \qquad \text{with} \qquad c := v/|v| = \pm 1. \tag{7}$$

After two integrations we have

$$(zz_\eta)^2 = f(z) \tag{8}$$

with

$$f(z) = z^4 + 2cz^3 + Az^2 + B = (z - z_1)(z - z_2)(z - z_3)(z - z_4),$$

where $f(z)$ is a polynomial of fourth order and is shown in Fig. 1.

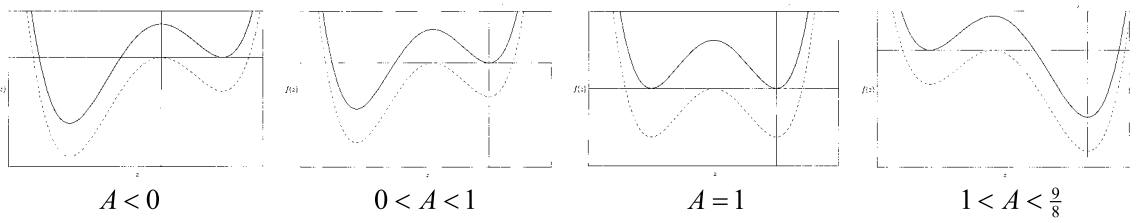

Figure 2. Four possible cases for the polynomial $f(z)$.

Analyzing equation (8), we observe that the roots of the polynomial $f(z)$ are real and the interval of integration is between the roots z_2 and z_3. We can write two forms of solution. The first form of solution is

$$z = \frac{z_2 - z_1 \operatorname{sn}^2(w|m)}{1 - n \operatorname{sn}^2(w|m)} \qquad \text{with} \qquad n = \frac{z_3 - z_2}{z_3 - z_1}, \tag{9}$$

where

$$w = p\zeta, \qquad p = \tfrac{1}{2}\sqrt{(z_4 - z_2)(z_3 - z_1)}, \qquad m = \frac{(z_3 - z_2)(z_4 - z_1)}{(z_4 - z_2)(z_3 - z_1)}$$

and

$$\eta = [wz_1 + (z_2 - z_1)\Pi(n; w|m)]/p. \tag{10}$$

Here $\operatorname{sn}(w|m)$ is a Jacobian elliptic function and $\Pi(n; w|m)$ is the elliptic integral of the third kind. The second form of solution is

$$z = \frac{z_3 - z_4 \operatorname{sn}^2(w|m)}{1 - n \operatorname{sn}^2(w|m)} \qquad \text{with} \qquad n = \frac{z_3 - z_2}{z_4 - z_2} \tag{11}$$

and

$$\eta = [wz_4 + (z_4 - z_3)\Pi(n; w|m)]/p. \tag{12}$$

Hence the solution is given in parametric form with w as a parameter. The solutions are characterized by the two parameters A and B, or equivalently A and m.

3 Classification of solutions

The equation (7) is invariant under the transformation $z \to -z$, $c \to -c$; this corresponds to the transformation $u \to -u$, $v \to -v$. Hence we need to consider only the case $c = 1$ (i.e. $v > 0$).

Four cases are possible for the polynomial $f(z)$ corresponding to different ranges of values of A (see Fig. 2). Examples of the corresponding solutions are illustrated in Fig. 3. In the first column are periodic solutions with $m \neq 1$. In the second column are the corresponding limiting cases with $m = 1$. These are solitary wave solutions, except for the figure in the second line which is a periodic peakon solution.

4 Conclusion

Travelling-wave solutions of the Degasperis–Procesi equation are investigated. The solutions are characterized by two parameters. Hump-like, loop-like and coshoidal periodic-wave solutions are found; hump-like, loop-like and peakon solitary-wave solutions are obtained as well.

Higher Conserved Quantities for the Multi-Centre Metrics

Galliano VALENT

Centre de Physique Theorique, CNRS Luminy Case 907, F-13288 Marseille Cedex 9, France
E-mail: *gvalent@cpt.univ-mrs.fr*

The multi-centre metrics are a family of Euclidean solutions of the empty space Einstein equations with self-dual curvature. We consider the Hamiltonian dynamics generated by the geodesic flow along the $U(1)$ fibers and obtain several metrics in this class which do exhibit an extra conserved quantity quadratic in the momenta. The corresponding systems are shown to be classically integrable.

1 Introduction

The integrability of the geodesic flow for the multi-centre metrics began with the discovery of the generalized Runge–Lenz vector for the Taub–NUT metric [1] and the derivation of its Killing–Stäckel tensor in [2]. It was generalized to the Eguchi–Hanson metric in [3] where the Hamilton–Jacobi equation was separated. A further progress led to the integrability proof of the full 2-centre metric [2] which includes Taub–NUT and Eguchi–Hanson as particular cases. Despite these successes, a systematic analysis of the full family of the multi-centre metrics was still lacking. We will present a new approach which will determine which metrics, in this class, do exhibit a quadratic Killing–Stäckel tensor leading to classical integrability.

2 Basic facts on the multi-centre metrics

These Euclidean and four dimensional metrics on M_4 have at least one Killing vector $\widetilde{\mathcal{K}} = \partial_t$. Fibrating along this Killing vector, we have for metric

$$g = \frac{1}{V}\,(dt + \Theta)^2 + V\,d\vec{x}\cdot d\vec{x}, \qquad V = V(x), \qquad \Theta = \Theta_i(x)\,dx^i, \tag{1}$$

where the x^i are the coordinates of the subspace orthogonal to the $U(1)$ fibers. The metric (1) is a solution of the empty space Einstein equations provided that we have the monopole equation

$$dV = \star\, d\Theta, \tag{2}$$

where the Hodge star refers to the flat 3-dimensional metric. Notice that the integrability condition for the monopole equation is $\Delta V = 0$. So to each solution of Laplace equation in a 3-dimensional *flat* space there corresponds a Ricci-flat four-dimensional metric: we have an exact linearization of the empty space Einstein equations!

These metrics have a richer geometry since they are endowed with a triplet of complex structures, with associated closed 2-forms

$$\Omega_i^{(-)} = E_0 \wedge E_i - \frac{1}{2}\,\epsilon_{ijk}\,E_j \wedge E_k = (dt + \Theta) \wedge dx_i - \frac{1}{2}\,V\,\epsilon_{ijk}\,dx_j \wedge dx_k. \tag{3}$$

It follows that the multi-centre metrics are hyper-Kähler, hence Ricci-flat.

As shown by [4], in the hyper-Kähler case, any Killing vector has to be either tri-holomorphic or holomorphic with respect to the triplet of complex structures (3). For instance $\widetilde{\mathcal{K}}$ is tri-holomorphic and this means that

$$\underset{\widetilde{\mathcal{K}}}{\mathcal{L}}\,\Omega_i^{(-)} = 0, \qquad i = 1,2,3,$$

whereas for an holomorphic Killing vector K we would have

$$\underset{K}{\mathcal{L}}\,\Omega_1^{(-)} = \Omega_2^{(-)}, \qquad \underset{K}{\mathcal{L}}\,\Omega_2^{(-)} = -\Omega_1^{(-)}, \qquad \underset{K}{\mathcal{L}}\,\Omega_3^{(-)} = 0.$$

The following drawings display the potentials for the general 2-centre metrics. For generic parameters we have two Killing vectors (the subscripts H or T refer to its holomorphic or tri-holomorphic nature). For special values of the parameters the isometry algebra is enhanced to $u(2)$ leading to either Taub–NUT or to Eguchi–Hanson metrics.

$$\begin{cases} \bullet \quad V = v_0 + \dfrac{m_1}{|\vec{x} - c\vec{e}_z|} + \dfrac{m_2}{|\vec{x} + c\vec{e}_z|} \\ \bullet \quad \text{isometries :} \;\; u(1)_{\mathrm{H}} \oplus u(1)_{\mathrm{T}} \end{cases}$$

$m_1 = m_2 \to m$

$c \to 0$

Taub–NUT

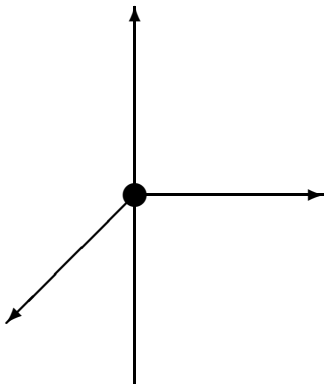
$$\begin{cases} \bullet \quad V = v_0 + \dfrac{m}{|\vec{x}|} \\ \bullet \quad \text{isometries :} \;\; su(2)_{\mathrm{H}} \oplus u(1)_{\mathrm{T}} \\ \bullet \quad a \;\text{ breaks }\; su(2)_{\mathrm{T}} \\ \bullet \quad \text{flat iff} \;\; v_0 = 0 \;\; \text{or} \;\; m = 0 \end{cases}$$

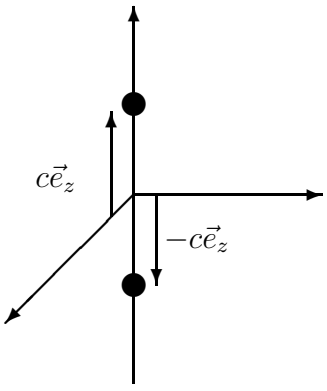
$m_1 = m_2 \to 1$

$v_0 \to 0$

Eguchi–Hanson

$$\begin{cases} \bullet \quad V = \dfrac{1}{|\vec{x} - c\vec{e}_z|} + \dfrac{1}{|\vec{x} + c\vec{e}_z|} \\ \bullet \quad \text{isometries :} \;\; u(1)_{\mathrm{H}} \oplus su(2)_{\mathrm{T}} \\ \bullet \quad c \;\text{ breaks }\; su(2)_{\mathrm{H}} \\ \bullet \quad \text{flat iff} \;\; c = 0 \end{cases}$$





2.1 Geodesic flow

The geodesic flow is the Hamiltonian flow of the metric considered as a function on the cotangent bundle of M_4. Using the coordinates (t, x_i) we will write a cotangent vector as

$$\Pi_i\, dx_i + \Pi_0\, dt,$$

and the symplectic form is

$$dx_i \wedge d\Pi_i + dt \wedge d\Pi_0.$$

We take for Hamiltonian

$$H = \frac{1}{2}\, g^{\mu\nu}\, \Pi_\mu\, \Pi_\nu == \frac{1}{2}\left(\frac{1}{V}\,(\Pi_i - \Pi_0\,\Theta_i)^2 + V\,\Pi_0^2\right).$$

For geodesics orthogonal to the $U(1)$ fibers and affinely parametrized by λ the equations for the flow allow on the one hand to express the velocities

$$\begin{aligned} \dot t &\equiv \frac{dt}{d\lambda} = \frac{\partial H}{\partial \Pi_0} = \left(V + \frac{\Theta^2}{V}\right)\Pi_0 - \frac{\Theta_i \Pi_i}{V}, \\ \dot x_i &\equiv \frac{dx_i}{d\lambda} = \frac{\partial H}{\partial \Pi_i} = \frac{1}{V}\, p_i, \qquad p_i = \Pi_i - \Pi_0\,\Theta_i, \end{aligned} \tag{4}$$

and on the other hand to get the dynamical evolution equations

$$\dot\Pi_0 = -\frac{\partial H}{\partial t} = 0, \qquad q \equiv \Pi_0 = \frac{(\dot t + \Theta_i\, \dot x_i)}{V}, \tag{5}$$

and

$$\dot\Pi_i = -\frac{\partial H}{\partial x_i} \quad \Longrightarrow \quad \dot p_i = \left(\frac{H}{V} - q^2\right)\partial_i V + \frac{q}{V}\,(\partial_i\Theta_s - \partial_s\Theta_i)\, p_s. \tag{6}$$

Relation (5) expresses the conservation of the charge q, a consequence of the $U(1)$ isometry of the metric. For the multi-centre metrics, use of relation (2) brings the equations of motion (6) to the nice form

$$\dot{\vec p} = \left(\frac{H}{V} - q^2\right)\vec\nabla\, V + \frac{q}{V}\,\vec p \wedge \vec\nabla V. \tag{7}$$

The conservation of the energy

$$H = \frac{1}{2}\left(\frac{p_i^2}{V} + q^2\, V\right) = \frac{V}{2}\left(\dot x_i^2 + q^2\right) = \frac{1}{2}\, g_{\mu\nu}\, \dot x^\mu\, \dot x^\nu$$

is obvious since it expresses the constancy of the length of the tangent vector $\dot x^\mu$ along a geodesic.

Hence at this stage we have already obtained two conserved quantities: $q = \Pi_0$ and H. Two more quantities are needed for integrability.

2.2 Killing–Stäckel tensors and their conserved quantities

A Killing–Stäckel (KS) tensor is a symmetric tensor $S_{\mu\nu}$ which satisfies

$$\nabla_{(\mu}\, S_{\nu\rho)} = 0. \tag{8}$$

Let us observe that if K and L are two (possibly different) Killing vectors their symmetrized tensor product $K_{(\mu}\, L_{\nu)}$ is a KS tensor. So we will define *irreducible* KS tensors as the ones

which cannot be written as linear combinations, with constant coefficients, of symmetrized tensor products of Killing vectors.

For a given KS tensor $S_{\mu\nu}$ the quadratic form of the velocities:

$$\mathcal{S} = S_{\mu\nu}\,\dot{x}^{\mu}\,\dot{x}^{\nu} \tag{9}$$

is preserved by the geodesic flow.

In all what follows we will look for KS tensors preserved by Lie dragging along the tri-holomorphic Killing vector:

$$\underset{\widetilde{\mathcal{K}}}{\mathcal{L}}\, S_{\mu\nu} = 0, \qquad \widetilde{\mathcal{K}} = \partial_t,$$

and we will consider *generic* values of H and $q \neq 0$.

Let us examine more closely the structure of the conserved quantity induced by such a KS tensor. Expanding the sums in (9) and using the relations (4) we obtain the following structure for the conserved quantity:

$$\mathcal{S} = A_{ij}(x_k)\,p_i\,p_j + 2q\,B_i(x_k)\,p_i + C(x_k), \tag{10}$$

where the various unknown functions, as a consequence of our hypotheses, are independent of the coordinate on the $U(1)$ fiber.

It is interesting to notice that the knowledge of $\mathcal{S}$ is *equivalent* to the knowledge of the KS tensor.

Imposing the conservation of $\mathcal{S}$ under the geodesic flow gives the following equations[1]

$$\begin{aligned}
&a) \quad q \cdot \underset{B}{\mathcal{L}}\, V = 0,\\
&b) \quad \partial_{(k}\,A_{ij)} = 0,\\
&c) \quad q(\partial_{(i}\,B_{j)} - A_{s(i}\,\epsilon_{j)su}\,\partial_u V) = 0,\\
&d) \quad \partial_i\,C + 2\left(H - q^2\,V\right)A_{is}\,\partial_s\,V - 2\,q^2\,\epsilon_{ist}\,B_s\,\partial_t V = 0.
\end{aligned} \tag{11}$$

The relation (11a) calls for a spatial Killing vector for the potential V. However it could well be that V has no symmetry at all. In this event we must have $B_i = 0$. Then relation (11c) can be written

$$[A, R] = 0, \qquad (R)_{ij} = \epsilon_{isj}\,\partial_s\,V.$$

Since V has no Killing the matrix R is a generic matrix in the Lie algebra $so(3)$. By Schur lemma it follows that A has to be proportional to the identity matrix and this does trivialize the corresponding conserved quantity $\mathcal{S}$. So the potential must have at least one extra spatial Killing vector L (notice that L lifts up to an isometry of the 4 dimensional metric).

The full discussion and integration of the system (11) has been worked out in [5] and the results can be classified according to wether the extra Killing vector is holomorphic or tri-holomorphic. For each potential the detailed form of the conserved quantity induced by the Killing–Stäckel tensor has been determined. Let us state these results.

3 One extra holomorphic Killing vector

We can take for extra spatial Killing vector $\widehat{\mathcal{L}} = x\partial_y - y\partial_x$. Then the metrics with the following potentials will exhibit a quadratic Killing–Stäckel tensor:

[1] Since H and q take generic values, the quantity $H - q^2V$ does not vanish identically.

1. The 2-centre metric with

$$V = v_0 + \frac{m_1}{r_+} + \frac{m_2}{r_-}, \qquad r_\pm = \sqrt{x^2 + y^2 + (z \pm c)^2}.$$

The conserved quantity is

$$\mathcal{S}_I = \vec{L}^{\,2} + c^2\, p_z^2 + 2\, qc\, \Delta\, L_z + 2cz\, \Delta \left(H - q^2 V\right) - q^2 r^2 \Delta^2, \qquad r^2 = x^2 + y^2 + z^2,$$

with

$$L_i = \epsilon_{ijk}\, x_j\, p_k, \qquad \Delta = \frac{m_1}{r_+} - \frac{m_2}{r_-}.$$

which we have checked to be in full agreement with [2].

2. A first dipolar breaking of Taub–NUT with

$$V = v_0 + \frac{m}{r} + F\frac{z}{r^3}, \qquad r = \sqrt{x^2 + y^2 + z^2},$$

which is, in fact, the singular limit $c \to 0$ of the previous case. The conserved quantity is

$$\mathcal{S}_{II} = \vec{L}^{\,2} - 2\, q\, \frac{F}{r}\, L_z - 2F\, \frac{z}{r}\, \left(H - q^2 v_0\right) + q^2\, F^2\, \frac{\left(x^2 + y^2\right)}{r^4}.$$

3. A second dipolar breaking of Taub–NUT with

$$V = v_0 + \frac{m}{r} + Ez.$$

The conserved quantity is

$$\mathcal{S}_{III} = (\vec{p} \wedge \vec{L})_z - q\, \left(\frac{m}{r} - E\, z\right) L_z - 2U\, \left(H - q^2 v_0\right) - 2q^2\, mE\, \frac{\left(x^2 + y^2\right)}{r}.$$

In the limiting case of Taub–NUT, we have in fact 3 extra Killing vectors, which are holomorphic. It follows that we will have 3 Killing–Stäckel tensors, giving rise to the generalized Runge–Lenz vector

$$\vec{\mathcal{S}} = \vec{p} \wedge \vec{J} + m\, \left(q^2 v_0 - H\right) \frac{\vec{r}}{r}, \qquad \vec{J} = \vec{L} + q\, \frac{m}{r}\, \vec{r},$$

discovered by Gibbons and Manton [1]. The conserved quantity $\mathcal{S}_{III}$ does reduce to $\mathcal{S}_z$ in the limit $E \to 0$.

All of these metrics have at least the 4 conserved quantities

$$q = \Pi_0, \qquad H, \qquad L^\mu \Pi_\mu, \qquad \mathcal{S},$$

which are easily checked to be in involution, thus establishing the Liouville integrability of their corresponding geodesic flows.

Let us consider the class of metrics with an extra tri-holomorphic Killing.

4 One extra tri-holomorphic Killing

Here we can take the Killing vector to be $\widehat{L} = \partial_z$ and since the potential does depend only on the coordinates x and y we will state the results using the complex coordinate $z = x + iy$. Then the metrics with the following potentials will exhibit a quadratic Killing–Stäckel tensor:

1. First case:

$$V = v_0 + m\frac{z}{\sqrt{z^2+c^2}} + \text{c.c.},$$

where c.c. means complex conjugation. The conserved quantity is

$$\mathcal{S}_1 = L_z^2 - c^2\,\Pi_x^2 - 2c^2F\,\Pi_0\,\Pi_z + c^2(2v_0U + D)\Pi_0^2 - 2c^2UH, \qquad c \neq 0,$$

with

$$U + iF = -m\,\frac{z+\overline{z}}{\sqrt{z^2+c^2}}, \qquad D = -2|m|^2\,\frac{\left(z^2+\overline{z}^2+|z|^2+c^2\right)}{|\sqrt{z^2+c^2}|^2}.$$

The Bianchi VII_0 and Bianchi VI_0, which appear as particular cases of these metrics for $v_0 = 0$ were already known to be integrable from [6].

2. Second case:

$$V = v_0 + \frac{m}{2z^2} + \text{c.c.}, \qquad m \in \mathbb{C},$$

with the conserved quantity

$$\mathcal{S}_2 = L_z^2 - 2F\,\Pi_0\,\Pi_z + 2v_0U\,\Pi_0^2 - 2UH, \qquad U + iF = m\,\frac{\overline{z}}{z}.$$

3. Third case:

$$V = v_0 + \frac{m}{\sqrt{z}} + \text{c.c.}, \qquad m \in \mathbb{C},$$

with the conserved quantity

$$\mathcal{S}_3 = \Pi_y\,L_z - 2F\,\Pi_0\,\Pi_z + (2v_0U + D)\Pi_0^2 - 2UH,$$

and

$$U + iF = -\frac{m}{2}\,\frac{z-\overline{z}}{\sqrt{z}}, \qquad D = |m|^2\,\frac{z+\overline{z}}{|\sqrt{z}|^2}.$$

4. The fourth case:

$$V = v_0 + m(z+\overline{z})/2, \qquad m \in \mathbb{R},$$

is super-integrable, with two conserved quantities

$$\mathcal{S}_4^{(1)} = \Pi_y^2 + (\Pi_z - my\,\Pi_0)^2, \qquad \mathcal{S}_4^{(2)} = \Pi_x\,\Pi_y - V\,\Pi_0(\Pi_z - my\,\Pi_0) - my\,H.$$

The parameter v_0 is always real.

Here too, all of these metrics have at least the 4 conserved quantities

$$q = \Pi_0, \qquad H, \qquad L^\mu\Pi_\mu, \qquad \mathcal{S},$$

which are easily checked to be in involution, thus establishing the Liouville integrability of their corresponding geodesic flows.

Construction of Special Solutions for Nonintegrable Dynamical Systems with the Help of the Painlevé Analysis

Sergey Yu. VERNOV

Skobeltsyn Institute of Nuclear Physics, Moscow State University, Vorob'evy Gory, 119992 Moscow, Russia
E-mail: *svernov@theory.sinp.msu.ru*

The generalized Hénon–Heiles system has been considered. In two nonintegrable cases with the help of the Painlevé test new special solutions have been found as Laurent series, depending on three parameters. The obtained series converge in some ring. One of parameters determines the singularity point location, other parameters determine coefficients of series. For some values of these parameters the obtained Laurent series coincide with the Laurent series of the known exact solutions. The Painlevé test can be used not only to construct local solutions as the Laurent series but also to find elliptic solutions.

1 The Painlevé property and integrability

A Hamiltonian system in a $2s$-dimensional phase space is called *completely integrable* (Liouville integrable) if it possesses s independent integrals that commute with respect to the associated Poisson bracket. When this is the case, the equations of motion are (in principal, at least) separable and solutions can be obtained by the method of quadratures.

When some mechanical problem is studied, time is assumed to be real, whereas the integrability of motion equations depends on the behavior of their solutions as functions of complex time. S.V. Kovalevskaya was the first who proposed [1] to interpret time as a complex variable and to require that solutions of mechanical problems have to be single-valued functions meromorphic in the entire complex plane. This idea gave a remarkable result: S.V. Kovalevskaya discovered a new integrable case (nowadays known as the Kovalevskaya's case) for the motion of a heavy rigid body about a fixed point [1] (see also [2,3]). The Kovalevskaya's result demonstrated that the analytic theory of differential equations can be fruitfully applied to mechanical and physical problems. The important stage of development of this theory was the Painlevé classification of ordinary differential equations (ODEs) with respect to the types of singularities of their solutions [4].

Let us formulate the Painlevé property for ODEs. Solutions of a system of ODEs regarded as analytic functions may have isolated singularity points [5,6]. A singularity point of a solution is said to be *critical* (as opposed to *noncritical*) if the solution is multivalued (single-valued) in its neighborhood and *movable* if its location depends on initial conditions. The *general solution* of an ODE of order N is the set of all solutions mentioned in the existence theorem of Cauchy, i.e. determined by the initial values. It depends on N arbitrary independent constants. A *special solution* is any solution obtained from the general solution by giving values to the arbitrary constants. A *singular solution* is any solution which is not special, i.e. which does not belong to the general solution.

Definition 1. A system of ODEs has ***the Painlevé property*** if its general solution has no movable critical singularity point [4].

Investigations of many dynamical systems [7] show that systems with the Painlevé property are completely integrable. Arguments, which clarify the connection between the Painlevé analysis and the existence of motion integrals, are presented in [8, 9]. At the same time the integrability of an arbitrary system with the Painlevé property has yet to be proved. There is no algorithm for construction of additional integrals by the Painlevé analysis. It is easy to give an example of an integrable system without the Painlevé property [10]. The system with the Hamiltonian $H = \frac{1}{2}p^2 + f(x)$, where $f(x)$ is a polynomial whose power is not lower than five, is trivially integrable, but its general solution is not a meromorphic function.

The study of complex-time singularities is a useful tool for analysis of not only integrable systems, but also of chaotic dynamics [11]. The Painlevé analysis can be connected to the normal form theory [12].

The ***Painlevé test*** is any algorithm that checks some necessary conditions for a differential equation to have the Painlevé property. The original algorithm, developed by P. Painlevé and used by him to find all the second order ODEs with the Painlevé property, is known as the α-method. The method of S.V. Kovalevskaya is not as general as the α-method, but much simpler. The remarkable property of this test is that it can be checked in a finite number of steps. This test can only detect the occurrence of logarithmic and algebraic branch points. Up to the present there is no general finite algorithmic method to detect the occurrence of essential singularities. Different variants of the Painlevé test are compared in [13, R. Conte paper].

Developing the Kovalevskaya method [1] further, M.J. Ablowitz, A. Ramani and H. Segur constructed a new algorithm of the Painlevé test for ODEs [14]. They also were the first to point out the connection between the nonlinear partial differential equations (PDEs) that are solvable by the inverse scattering transform method, and ODEs with the Painlevé property. Subsequently the Painlevé property for PDEs was defined and the corresponding Painlevé test (the WTC procedure) was constructed [15, 16] (see also [13, 17]). With the help of this test it was found that all PDEs solvable by inverse scattering transforms, have the Painlevé property, maybe after some change of variables. For many integrable PDEs, for example, the Korteweg–de Vries equation [7], the Bäcklund transformations and the Lax representations result from the WTC procedure [16, 18]. For certain nonintegrable PDEs special solutions were constructed using this algorithm [19, 20].

The algorithm for finding of special solutions for ODEs into the form of a finite expansion in powers of unknown function $\varphi(t - t_0)$ was constructed in [21, 22]. The function $\varphi(t - t_0)$ and coefficients have to satisfy some system of ODE, often simpler than an initial one. This method has been used to construct exact special solutions for some nonintegrable ODEs [23, 24]. With the help of the perturbative Painlevé test [17] a four-parameter generalization of an exact three-parameter solution of the Bianchi IX cosmological model was constructed [25].

2 The Hénon–Heiles Hamiltonian

In the 1960s the models of the star motion in an axial-symmetric and time-independent potentials were developed to show either existence or absence of the third integral for some polynomial potentials. Due to the symmetry of the potential the considered system is equivalent to two-dimensional one. To clarify the question of the existence of the third integral Hénon and Heiles [26] considered behavior of numerically integrated trajectories. Emphasizing that their choice does not proceed from experimental data, they have proposed the Hamiltonian

$$H = \frac{1}{2}\left(x_t^2 + y_t^2 + x^2 + y^2\right) + x^2 y - \frac{1}{3}y^3,$$

because on the one hand, it is analytically simple; this makes the numerical computations of trajectories easy; on the other hand, it is sufficiently complicated to give trajectories that are

far from trivial. Indeed, for low energies the Hénon–Heiles system appears to be integrable, in so much as trajectories (numerically integrated) always lay on well-defined two-dimensional surfaces. On the other hand, for high energies many of these integral surfaces are destroyed, it points to absence of the third integral.

The generalized Hénon–Heiles system is described by the Hamiltonian:

$$H = \frac{1}{2}\left(x_t^2 + y_t^2 + \lambda x^2 + y^2\right) + x^2 y - \frac{C}{3}\, y^3 \tag{1}$$

and the corresponding system of the motion equations:

$$\begin{aligned} x_{tt} &= -\lambda x - 2xy, \\ y_{tt} &= -y - x^2 + Cy^2, \end{aligned} \tag{2}$$

where $x_{tt} \equiv \frac{d^2x}{dt^2}$ and $y_{tt} \equiv \frac{d^2y}{dt^2}$, λ and C are numerical parameters.

The generalized Hénon–Heiles system is a model, not only actively investigated by various mathematical methods (see [27] and references therein), but also widely used in physics, in particular, in gravitation [28, 29]. The models, described by the Hamiltonian (1) with some additional nonpolynomial terms, are actively studied as well [30–32].

Due to the Painlevé analysis the following integrable cases of (2) were found:

(i) $C = -1$, $\lambda = 1$,
(ii) $C = -6$, λ is an arbitrary number,
(iii) $C = -16$, $\lambda = 1/16$.

The general solutions in the analytic form are known only in integrable cases [31, 32], in other cases not only four-, but even three-parameter exact solutions have yet to be found. In nonintegrable cases local four-parameter solutions as converging psi-series solutions were found [33] for all values of the parameter C, except $C = -2$. The Ablowitz–Ramani–Segur algorithm of the Painlevé test appears very useful to find such values of parameter at which three-parameter solutions can be expanded into formal Laurent series and to construct these local solutions. The knowledge of local solutions can be used to find solutions in the analytical form.

Let us assume that the behavior of solutions in a sufficiently small neighborhood of the singularity point is algebraic, i.e., x and y tend to infinity as

$$x = a_\alpha (t - t_0)^\alpha \qquad \text{and} \qquad y = b_\beta (t - t_0)^\beta,$$

where α, β, a_α and b_β are some constants.

The Painlevé test gives all information about behavior of solutions in the neighborhood of the singularity point (see, for example, [7]). There exist two possible variants of dominant behavior and resonance structure of solutions of the generalized Hénon–Heiles system [7, 33]:

Case 1:	*Case 2*: ($\beta < \Re e(\alpha)$)
$\alpha = -2$,	$\alpha = \frac{1 \pm \sqrt{1-48/C}}{2}$,
$\beta = -2$,	$\beta = -2$,
$a_\alpha = \pm 3\sqrt{2+C}$,	$a_\alpha = c_1$ (an arbitrary number),
$b_\beta = -3$,	$b_\beta = \frac{6}{C}$,
$r = -1,\ 6,\ \frac{5}{2} - \frac{\sqrt{1-24(1+C)}}{2},\ \frac{5}{2} + \frac{\sqrt{1-24(1+C)}}{2}$	$r = -1,\ 0,\ 6,\ \mp\sqrt{1 - \frac{48}{C}}$

The values of r denote resonances: $r = -1$ corresponds to arbitrary parameter t_0; $r = 0$ (in the *Case 2*) corresponds to arbitrary parameter c_1. Other values of r determine powers of t, to be exact, $t^{\alpha+r}$ for x and $t^{\beta+r}$ for y, at which new arbitrary parameters can appear.

For integrability of system (2) all values of r have to be integer and all systems with zero determinants have to have solutions at any values of free parameters. It is possible only in the integrable cases (i)–(iii).

Those values of C, at which r are integer numbers either only in the *Case 1* or only in the *Case 2*, are of interest for search of special three-parameter solutions. Those cases where an additional negative resonance is present likely correspond to singular, rather the general, solutions [7].

Let us consider all cases, when there exist special (not singular) solutions, representable as three-parameter Laurent series (maybe, multiplied on $\sqrt{t-t_0}$). From the requirement that all values of r but one are integer and nonnegative numbers, we obtain the following values of C: $C=-1$, $C=-4/3$ (the *Case 1*), $C=-16/5$, $C=-6$, $C=-16$ (the *Case 2*, $\alpha=\frac{1-\sqrt{1-48/C}}{2}$) and $C=-2$, when two types of singular behavior coincide.

At $C=-2$ (in the *Case 1*) $a_\alpha=0$. This is the consequence of the fact that, contrary to our assumption, the behavior of the solution in the neighborhood of a singularity point is not algebraic, because its dominant term includes logarithm [7]. At $C=-6$ and any value of λ exact four-parameter solutions are known. In cases $C=-1$ and $C=-16$ substitution of unknown function as Laurent series gives the equations in λ: accordingly $\lambda=1$ and $\lambda=1/16$; hence, in nonintegrable cases special three-parameter local solutions have to include logarithmic terms. Single-valued three-parameter special solutions can exist only in two nonintegrable cases, at $C=-16/5$ and at $C=-4/3$.

3 New solutions

Let us consider the Hénon–Heiles system with $C=-16/5$. In the *Case 1* some values of r are not rational. To find special three-parameter solutions we consider the *Case 2*. In this case $\alpha=-3/2$ and $r=-1,\ 0,\ 4,\ 6$, hence, in the neighborhood of the singularity point t_0 we have to seek x in such a form that x^2 can be expanded into Laurent series, beginning with $(t-t_0)^{-3}$. Let $t_0=0$, substituting

$$x=\sqrt{t}\left(c_1t^{-2}+\sum_{j=-1}^{\infty}a_jt^j\right)\qquad\text{and}\qquad y=-\frac{15}{8}t^{-2}+\sum_{j=-1}^{\infty}b_jt^j \tag{3}$$

in (2), we obtain the following sequence of linear system in a_k and b_k:

$$\begin{aligned}&\left(k^2-4\right)a_k+2c_1b_k=-\lambda a_{k-2}-2\sum_{j=-1}^{k-1}a_jb_{k-j-2},\\&((k-1)k-12)b_k=-b_{k-2}-\sum_{j=-2}^{k-1}a_ja_{k-j-3}-\frac{16}{5}\sum_{j=-1}^{k-1}b_jb_{k-j-2}.\end{aligned} \tag{4}$$

The determinants of the systems (4) corresponding to $k=2$ and $k=4$ are equal to zero. To determine a_2 and b_2 we have the following system:

$$\begin{aligned}&c_1\big(557056c_1^8+(15552000\lambda-4860000)c_1^4+864000000b_2\\&\qquad+108000000\lambda^2-67500000\lambda+10546875\big)=0,\\&818176c_1^8+(15660000\lambda-4893750)c_1^4-810000000b_2-6328125=0.\end{aligned} \tag{5}$$

It is easy to see that this system contains no terms proportional to a_2, therefore, a_2 is the new constant of integration. We discard the solution with $c_1=0$ and obtain the system in c_1^4

and b_2. System (5) has solutions only if

$$c_1^4 = \frac{1125\left(525 - 1680\lambda \pm 4\sqrt{35(2048\lambda^2 - 1280\lambda + 387)}\right)}{167552}.$$

We obtain new constant of integration a_2, but we must fix c_1, so number of constants of integration is equal to 2. It is easy to verify that b_4 is an arbitrary parameter, because the corresponding system is equivalent to one linear equation. System (2) is invariant under exchange x to $-x$, so we obtain four different local solutions which depend on three parameters, namely t_0, a_2 and b_4. With the help of some computer algebra system, for example, **REDUCE** [34], these solutions can be obtained with arbitrary accuracy. For the case $\lambda = 1/9$ the obtained Laurent series are presented in [35].

At $C = -4/3$ the situation is similar. In the *Case 1* we have $r = -1,\ 1,\ 4,\ 6$. Substituting

$$x = \sqrt{6}t^{-2} + \sum_{k=-1}^{\infty} d_k t^k \qquad \text{and} \qquad y = -3t^{-2} + \sum_{k=-1}^{\infty} f_k t^k \tag{6}$$

in system (2), we receive a sequence of linear systems in d_k and f_k:

$$\begin{aligned}
&((k-1)k-6)d_k + 2\sqrt{6}f_k = -\lambda d_{k-2} - 2\sum_{j=-1}^{k-1} d_j f_{k-j-2},\\
&2\sqrt{6}d_k + ((k-1)k-8)f_k = -f_{k-2} - \sum_{j=-1}^{k-1} d_j d_{k-j-2} - \frac{4}{3}\sum_{j=-1}^{k-1} f_j f_{k-j-2}.
\end{aligned} \tag{7}$$

The determinants of the systems (7) corresponding to $k = -1,\ 2,\ 4$ are equal to zero. The first system ($k = -1$) always has infinite number of solutions and f_{-1} is a parameter. We have to fix this parameter to solve the system corresponding to $k = 2$. This system has solutions only if

$$f_{-1}^2 = \frac{105 - 140\lambda \pm \sqrt{7\big(1216\lambda^2 - 1824\lambda + 783\big)}}{385} \qquad \text{or} \qquad f_{-1} = 0.$$

At $k = 4$ system (7) is reduced to one equation. Thus, at $C = -4/3$ we have five three-parameter (t_0, f_2 and f_4) solutions.

The convergence of all the Laurent series solutions on some real time interval have been proved in [33]. For the obtained solutions it is easy to find conditions at which the series converge at $0 < |t| \leqslant 1 - \varepsilon$, where ε is any positive number. Our series converge in the above-mentioned ring, if $\exists\, N$ and $\exists\, M$ such that $\forall\, n > N \ \ |a_n| \leqslant M$ and $|b_n| \leqslant M$. Let $|a_n| \leqslant M$ and $|b_n| \leqslant M$ for all $-1 < n < k$, then (in the case $C = -16/5$) from (4) we obtain:

$$|a_k| \leqslant \frac{2M(k+1) + |\lambda| + 2|c_1|}{|k^2 - 4|}M, \qquad |b_k| \leqslant \frac{21Mk + 26M + 5}{5|k^2 - k - 12|}M.$$

It is easy to see that there exists such N that if $|a_n| \leqslant M$ and $|b_n| \leqslant M$ for $-1 \leqslant n \leqslant N$, then $|a_n| \leqslant M$ and $|b_n| \leqslant M$ for $-1 \leqslant n < \infty$. So one can prove the convergence, analyzing values of a finite number of the first coefficients of series. For $C = -4/3$ it is easy to obtain the analogous result.

4 Global single-valued solutions

We have found some local three-parameter solutions. To seek for the global single-valued solutions we transform system (2) into the fourth order equation [36, 37]:

$$y_{tttt} = (2C-8)y_{tt}y - (4\lambda+1)y_{tt} + 2(C+1)y_t^2 + \frac{20C}{3}y^3 + (4C\lambda - 6)y^2 - 4\lambda y - 4H. \tag{8}$$

Point out that the energy of the system H and initial data y_0, y_{0t}, y_{0tt} and y_{0ttt} are dependent. If $y_{0tt} = Cy_0^2 - y_0$, then there exists the connection $y_{0ttt} = 2Cy_0y_{0t} - y_{0t}$, in opposite case H is a function of initial data.

There are some reasons to seek three-parameter solutions of equation (8) in terms of elliptic functions. In 1999 E.I. Timoshkova [37] found that the general solution of the following equation:

$$y_t^2 = \tilde{\mathcal{A}}y^3 + \tilde{\mathcal{B}}y^2 + \tilde{\mathcal{C}}y + \tilde{\mathcal{D}} + \tilde{\mathcal{G}}y^{5/2} + \tilde{\mathcal{E}}y^{3/2}$$

with some values of constants $\tilde{\mathcal{A}}$, $\tilde{\mathcal{B}}$, $\tilde{\mathcal{C}}$, $\tilde{\mathcal{D}}$, $\tilde{\mathcal{G}}$ and $\tilde{\mathcal{E}}$, is one-parameter solution of equation (8) in each of two above-mentioned nonintegrable cases ($C = -4/3$ or $C = -16/5$, λ is an arbitrary number). If $\tilde{\mathcal{G}} = 0$ and $\tilde{\mathcal{E}} = 0$ we obtain the well-known solutions in terms of the Weierstrass elliptic function. Solutions with $\tilde{\mathcal{G}} \neq 0$ or $\tilde{\mathcal{E}} \neq 0$ are derived only at $\tilde{\mathcal{D}} = 0$, therefore, substitution $y(t) = \varrho(t)^2$ gives:

$$\varrho_t^2 = \frac{1}{4}\big(\tilde{\mathcal{A}}\varrho^4 + \tilde{\mathcal{G}}\varrho^3 + \tilde{\mathcal{B}}\varrho^2 + \tilde{\mathcal{E}}\varrho + \tilde{\mathcal{C}}\big). \tag{9}$$

Two-parameter solutions $y(t) = \varrho(t)^2 + P_0$, where P_0 is an arbitrary constant and $\varrho(t)$ satisfies equation (9), were obtained in [38,39]. These solutions are the following elliptic functions

$$y(t - t_0) = \left(\frac{a\wp(t - t_0) + b}{c\wp(t - t_0) + d}\right)^2 + P_0, \qquad ad - bc = 1, \tag{10}$$

where $\wp(t - t_0)$ is the Weierstrass elliptic function, a, b, c and d are some constants. The parameter P_0 defines the energy of the system. There exist two different elliptic solutions for each possible pair of values of C and λ.

Let us consider the three-parameter solutions that were obtained at $C = -4/3$. If we choose $f_{-1} = 0$, then we obtain the solution which generalizes the well-known two-parameter solution in terms of Weierstrass elliptic functions. Other solutions generalize two-parameter solutions, obtained in [39]. The coefficient f_{-1} is a residue of y. The sum of residues of an elliptic function in its parallelogram of periods has to be zero [40], hence, two local solutions with opposite signs of f_{-1} correspond to one global elliptic solution. The obtained local three-parameter solution generalizes the Laurent series of the two-parameter elliptic solutions in the form (10).

For $C = -16/5$ we obtained four local solutions, which generalize two global elliptic solutions in the form (10). So, each obtained local three-parameter solution generalize the Laurent series of some two-parameter elliptic solution, and we can assume that unknown global three-parameter solutions are elliptic functions.

Of course, solutions, which are single-valued in the neighborhood of one singularity point, can be multivalued in the neighborhood of another singularity point. So, we can only assume that global three-parameter solutions are single-valued. If we assume this and, moreover, that these solutions are elliptic functions (or some degenerations of them), then we can seek them as solutions of some polynomial first order equations. The classical theorem, which was established by Briot and Bouquet [41], proves that if the general solution of the autonomous polynomial first order ODE is single-valued, then this solution is either an elliptic function, or a rational function of $e^{\gamma x}$, γ being some constant, or a rational function of x. Note that the third case is a degeneracy of the second one that in its turn is a degeneracy of the first one. At the same time, there exist elementary functions, for example, the function $f(t) = t + \sin(t)$ that are not solutions of any first order polynomial ODE.

A second result, of immediate practical use, is due to P. Painlevé [4]. He has proved that if the general solution of the autonomous polynomial first order ODE is single-valued, then the necessary form of this ODE is

$$F(y, y_t) \equiv \sum_{k=0}^{m} \sum_{j=0}^{2m-2k} h_{jk} y^j {y_t}^k = 0, \qquad h_{0m} = 1, \tag{11}$$

in which m is a positive integer number and the h_{jk} are constants.

In 2003 R. Conte and M. Musette have proposed a new method to find elliptic solutions [42]. This method is based on the Painlevé test and uses the Laurent series expansion to find the analytic form of elliptic solutions. Rather than substitute the first-order equation (11) into equation (8) one can substitute the found Laurent series of solutions of equation (8), for example, either solution (3) or solution (6), into equation (11) and obtain a linear system in h_{jk}. This method is more powerful than the traditional method and allows in principle to find all elliptic solutions. I hope that the use of this method allows finding of the three-parameter elliptic solutions.

5 Conclusion

Using the Painlevé analysis one can not only find integrable cases of dynamical systems, but also construct special solutions in nonintegrable cases.

We have found the special solutions of the Hénon–Heiles system with $C = -16/5$ and $C = -4/3$ as Laurent series depending on three parameters. For some values of these parameters the obtained solutions coincide with the known exact periodic solutions. There are no obstacles to existence of three-parameter single-valued solutions, so the probability of finding of exact three-parameter solutions that generalize the solutions obtained in [37, 39] is high.

Explicitly Reducible Integrable Natural Systems with the Integral of Full Momentum

Andrij VUS and Sergiy PIDKUYKO

Franko Lviv National University, 1 Universytets'ka Str., 79000 Lviv, Ukraine
E-mail: *matmod@franko.lviv.ua*

This paper is devoted to the problem of exact reduction of natural Hamiltonian systems. The integrable Hamiltonian systems with the full collection of first integrals being polynomial in the momenta, are considered. It is proved, that the corresponding reduced (with respect to the full momentum) Hamiltonian system possesses the full collection of first integrals, which are also polynomial in the momenta.

1 Introduction

Numerous achievements in the problem of complete integrability of the finite-dimensional Hamiltonian systems are connected with the projection method, i.e. using the known first integral one can reduce the above mentioned system to system with less number of degrees of freedom. Unfortunately, the symmetry of the reduced system often possesses imperceptible symmetry, which is hard to observe. A lot of corresponding examples for this problem are considered in [1,2]. The correspondence between the full collections of involutory integrals for the initial and reduced systems is not still described. In this paper we propose the description of such correspondence for the Hamiltonian systems admitting the full collection of first integrals, which are polynomial in the momenta. This result was first considered for the case $n = 2$ and proved in [3]. We generalize it for any $n \in \mathbb{N}$. Suppose the natural Hamiltonian system with the Hamiltonian

$$\mathcal{H} = \frac{1}{2}\sum_{i=1}^{n} p_i^2 + W(x_1, x_2, \ldots, x_n) \tag{1}$$

is integrable by Liouville and also admits the first integral (the full momentum)

$$\mathcal{P} = \sum_{i=1}^{n} p_i.$$

The following problem arises: is it possible to state that the reduced (in regard to $\mathcal{P}$) Hamiltonian system (now with $n-1$ degrees of freedom) is also integrable by Liouville? The equivalent formulation is: *does this system also admit a full collection of integrals containing the full momentum* $\mathcal{P}$? In this paper we consider the class of n-dimensional Hamiltonian natural systems with the Hamiltonian (1).

2 Principles of exact reduction

Lemma 1. *There exists the linear canonical transformation* $y = Ax$, $p = A^t q$, *such that in new phase coordinates* (y, q) *the Hamiltonian* (1) *takes the form*

$$\mathcal{H} = \frac{1}{2}\sum_{i=1}^{n} q_i^2 + W(y_1, y_2, \ldots, y_{n-1}),$$

where the full momentum is now $\mathcal{P} = q_n$.

Proof. The proof is based on the following remark. Obviously, there exists the orthogonal matrix $A \in SL_n(\mathbb{R})$ with the last row $a_{n1} = a_{n2} = \cdots = a_{nn} = 1/\sqrt{n}$. Therefore the above-stated transformation is canonical as the expansion of the punctual transformation of the configurational variables. ■

Further on we shall denote the new canonical coordinates and momenta as (x, p) and consider the system with the Hamiltonian

$$\mathcal{H} = \frac{1}{2}\sum_{i=1}^{n} p_i^2 + W(x_1, x_2, \ldots, x_{n-1}). \tag{2}$$

Lemma 2. *Let $F(x,p)$ be a polynomial in the momenta first integral of the system with the Hamiltonian* (2)*. Then*

1) $\frac{\partial F}{\partial p_n}$ *is also the first integral of this system;*
2) F *is a polynomial in* x_n*.*

Proof. Obviously, $\{\frac{\partial F}{\partial x_n}, \mathcal{H}\} = \frac{\partial}{\partial x_n}\{F, \mathcal{H}\} = 0$. As $F(x,p)$ is a polynomial in the momenta, it can be represented in the form

$$F = F_m + F_{m-1} + \cdots + F_0,$$

where the component F_k is a homogeneous polynomial of degree k in the momenta $p_1, \ldots, p_n$. Then for the upper part F_m we obtain that the Poisson bracket $\{F_m, \frac{1}{2}\sum\limits_{i=1}^{n} p_i^2\} = 0$, i.e. $\sum\limits_{i=1}^{n} \frac{\partial F}{\partial x_i} = 0$. Therefore F_m is a polynomial in the collection of its arguments

$$\{\, p_i \mid i \in \overline{1,n}\,\} \cup \{(x_i p_j - x_j p_i) \mid i, j \in \overline{1,n}\},$$

hence the degree in the momenta of the polynomial $(\frac{\partial}{\partial x_n})^{n+1} F$ is less than n. Consequently, $(\frac{\partial}{\partial x_n})^{n(n+1)/2} F = 0$. ■

Now we consider the possibility of the reduction of Hamiltonian system with the Hamiltonian (2) to the problem with $(n-1)$ degrees of freedom and the Hamiltonian

$$\mathcal{H}_0 = \frac{1}{2}\sum_{i=1}^{n-1} p_i^2 + W(x_1, x_2, \ldots, x_{n-1}). \tag{3}$$

in the following sense:

1) the initial system also admits the existing of the involutory collection of first integrals in the form $\Omega = (\mathcal{H} = F_1, F_2, \ldots, F_{n-1}, p_n)$;
2) $\Omega_0 = (\mathcal{H}_0 = F_1, F_2, \ldots, F_{n-1})$ is the involutory collection of first integrals for the reduced system with the Hamiltonian (3).

Notice that the integrals $F_1, \ldots, F_{n-1}$ have to be independent of x_n.

Theorem 1. *Let the Hamiltonian system with Hamiltonian* (2) *admit a full collection of the first integrals*

$$\{\mathcal{H} = F_1, F_2, \ldots, F_n\}$$

(that is, it is functionally independent and in involution), where the integrals $F_2, \ldots, F_n$ are polynomials in the momenta $p_1, p_2, \ldots, p_n$. Then this system also admits a full collection of integrals $\{\mathcal{H}_0, R_1, \ldots, R_{n-1}, p_n\}$, where the integrals R_i are polynomials in the momenta $p_1, p_2, \ldots, p_n$, independent of x_n.

Proof. Under conditions of the Theorem, rank $(\mathcal{H} = F_1, \dots, F_n) = n$ in all points of the phase space. Obviously, the elements of the collection Ω can be described in the form

$$F_i = F_{im_i} x_n^{m_i} + F_{im_i-1} x_n^{m_i-1} + \cdots + F_{i1} x_n + F_{i0}, \tag{4}$$

i.e. F_i are polynomials of degree m_i in the coordinate x_n, in addition $0 = m_1 \le m_2 \le \cdots \le m_n$. Denote

$$F_i^{(s)} = \frac{(m_i - s)!}{m_i!} \left(\frac{\partial}{\partial x_n} \right)^{(m_i - s)} F_i.$$

Then, evidently, $F_i^{(0)}$ is the coefficient F_{im_i} in the expansion (4).

Definition 1. The collection of the first integrals

$$\widetilde{\Omega} = \{\mathcal{H} = \widetilde{F}_1, \widetilde{F}_2, \dots, \widetilde{F}_n\}$$

is called to be a *minimal* collection of first integrals, if the following conditions hold:

1) the integrals $\widetilde{F}_i$ are put in ascending order of its degrees $\widetilde{m}_i$;
2) exactly k $(k > 0)$ of first integrals $\widetilde{F}_i$ are independent of x_n, i.e. $\widetilde{m}_k = 0 < \widetilde{m}_{k+1}$;
3) all the leading components $F_i^{(0)}$ $(k + 1 \le i \le n)$ are functionally independent with the collection $\{\mathcal{H} = \widetilde{F}_1, \widetilde{F}_2, \dots, \widetilde{F}_k\}$;
4) all the leading components $F_i^{(0)}$ (including those for $1 \le i \le k$) are in involution;
5) Any collection $\widetilde{\widetilde{\Omega}}$, which satisfies the conditions 1–4, is not smaller (in lexicographic order with respect to the ascending sequence $\{m_i\}$) than the collection $\widetilde{\Omega}$.

Definition 2. The collection Ω of the first integrals is called to be *almost involutory*, if for any pair of the first integrals F_s and F_t, such that their orders m_s and m_t are nonzero, the following identity holds:

$$\{ (\partial/\partial x_n)^{m_s - 1} F_s, (\partial/\partial x_n)^{m_t} F_t \} = \{ (\partial/\partial x_n)^{m_t - 1} F_t, (\partial/\partial x_n)^{m_s} F_s \}.$$

It is clear that the class of the collections $\widetilde{\Omega}$, which satisfy the Definitions 1, 2, is nonempty. Therefore further the collection Ω will be considered to satisfy the Definitions 1, 2. Note that according to the Definition 2, we remove the restriction for all the first integrals F_i to be in involution.

Lemma 3. *If the collection Ω of n functionally independent first integrals is minimal and almost involutory, then $k > n - 3$.*

Proof. Assume that there is more than 2 first integrals, dependent on x_n, belonging to the collection Ω. It easy to show that the degrees of these integrals are equal to 1. Indeed, consider the collection $\omega = \{F_i \in \Omega \,|\, \deg_{x_n} F_i > 0\}$, i.e. $\omega = \{F_{k+1}, \dots, F_n\}$. Consider now the following two cases:

Case 1. $m_{k+1} = 1$. If $\deg_{x_n} F_n > 1$, then, according to the definition of minimal collection, $(\partial/\partial x_n) F_n$ is functionally dependent with $\{F_1, F_2, \dots, F_{n-1}\}$. At the same time, the collection $\widetilde{\omega} = \{F_{k+1}, \dots, F_n + F_{k+1}\}$ is also minimal, and for this modified set we also can state, that $(\partial/\partial x_n)(F_n + F_{k+1}$ is functionally dependent with $\{F_1, F_2, \dots, F_{n-1}\}$. It follows from two previous statements, that $(\partial/\partial x_n) F_{k+1} = F_{k+1}^{(0)}$ is functionally dependent with $\{F_1, F_2, \dots, F_{n-1}\}$. As $F_{k+1}^{(0)}$ does not depend on x_n, is in involution with the first integrals from the set $(\Omega \backslash \omega)$, then it

functionally depends on at least one (say, the integral F_s) of the integrals $\{F_{k+2}, \dots, F_n\}$. Therefore, after substitution $(\partial/\partial x_n)F_{k+1}$ instead of F_s we obtain the collection, which is smaller (in lexicographic order) then Ω. More precisely, the new collection has smaller number of the integrals, essentially dependent on x_n.

Case 2. $m_{k+1} > 1$. In this case, according to the definition of minimal collection, $(\partial/\partial x_n)F_{k+1}$ is functionally dependent with $\{F_1, F_2, \dots, F_k, F_{k+2}, \dots, F_n\}$. As $(\partial/\partial x_n)F_{k+1}$ depends on x_n, it essentially depends on at least one (say, the integral F_s) of the integrals $\{F_{k+2}, \dots, F_n\}$. Therefore, after substitution $(\partial/\partial x_n)F_{k+1}$ instead of F_s we obtain the collection, which is smaller (in lexicographic order) then Ω. This contradiction with assumption of the minimality of Ω proves the Lemma 3. ■

To complete the proof of the Theorem, we notice, that for the case $k > n - 2$ only one or two of the first integrals in the collection Ω essentially depend on the coordinate x_n. Therefore, the statement of the main theorem in [3] can be easy transformed to be applied for n degrees of freedom. ■

The similar statement for the system with the Hamiltonian (1) with a full collection of the first integrals being analytical in the momenta is still open.

We report on the possibility of unidirectional motion of a topological soliton in a dissipative AC-driven sine-Gordon equation. This motion is due to breaking of certain space-time symmetries. It can be achieved by the proper choice of the potential or the AC force. We formulate the necessary symmetry conditions for the AC force and confirm them with the first order perturbation theory and numerical simulations. The same symmetry considerations are applied to the discrete sine-Gordon equation.

1 Introduction

Transport phenomena based on nonlinear effects are at the heart of many problems in physics. In this context the problem of creation of a net DC current from signals of zero mean is of particular interest [1]. Historically this problem has been posed by Smolouchowski and Feynmann (see [2]) under the name of the *ratchet* effect. It can be described as a Brownian particle in an asymmetric periodic potential, moving in a specific direction in presence of damping under the action of AC forces of zero average. The origin of a net motion is associated with the breaking of space-temporal symmetries of the system [3, 4]. The effect, originally studied for Brownian particles, was generalized to soliton systems with asymmetric potentials [5]. On the other hand, it is known that for a particle an *unidirectional* transport is possible also in symmetric periodic potentials, provided the driving force breaks certain *temporal* symmetries which relate orbits of opposite velocities in phase space [3]. Since in applications it is easier to act on the temporal part (by using external forces) than on the spatial part (by inducing distortion of the potential) of the system, we aim to explore the effect of the temporal symmetry breaking on soliton dynamics.

2 Sine-Gordon equation

Solitons are nonlinear waves that are spatially localized, move with constant velocity and collide elastically. Among the equations that have soliton solutions, the sine-Gordon (SG) equation

$$u_{tt} - u_{xx} = -\sin u, \tag{1}$$

takes a special place. This equation has a number of applications in condensed matter physics, quantum field theory and other areas of modern science. It has soliton solutions in the form of kinks and antikinks: $u(x,t) = 4\tan^{-1}\left[\exp\left(\pm(x-vt)/\sqrt{1-v^2}\right)\right]$. The sign "+" stands for the kink while "−" stands for the antikink. Kinks and antikinks come as a one-parametric family of solutions with the velocity v as a parameter. The velocity spectrum for kinks and antikinks is symmetric with respect to zero: $-1 < v < 1$. In the unperturbed version the solitons of the

SG equation have well-defined particle properties with their mass, energy, momentum

$$P = -\int_{-\infty}^{+\infty} u_x u_t dx, \tag{2}$$

and topological charge

$$Q = \frac{1}{2\pi}\int_{-\infty}^{+\infty} u_x dx. \tag{3}$$

For kinks $Q = 1$ while for antikinks $Q = -1$. For brevity, further on we will consider only kinks. If a weak perturbation is added the particle properties of the topological soliton will survive. The dynamics of the soliton can be approximately described by the dynamics of its center of mass. Thus, one could define the soliton velocity as

$$v = \frac{1}{2\pi}\int_{-\infty}^{+\infty} x u_{xt} dx, \tag{4}$$

bearing in mind that it works only if the soliton can be approximated as a particle, e.g. when the perturbation is weak enough.

We are interested in the AC-driven and damped sine-Gordon (SG) equation

$$u_{tt} - u_{xx} + \sin u = -\alpha u_t + E(t) \equiv \epsilon f(t), \qquad \langle E(t)\rangle_t = 0, \tag{5}$$

where $E(t) = E(t+T)$ is a periodic field with zero mean and α stands for the damping coefficient. For our problem the boundary conditions can be either periodic: $u(x+L,t) = u(x,t) + 2\pi$, $u_x(x+L,t) = u_x(x,t)$, or free ends: $u_x(0,t) = u_x(L,t) = 0$. If the size of the system L is much larger then the size of the soliton, for our purposes both cases should yield the same result. For practical tasks, mostly connected with soliton dynamics in Josephson junctions, the choice of boundary conditions means different physical situations, but this is out of scope of this paper.

Now our aim is to formulate general conditions on the driving field $E(t)$ that will provide directed motion of a soliton. All symmetry operations (see for details [6, 7]) that can relate a soliton solution $u(x,t;v)$ having velocity v with the identical solution but with velocity $-v$

$$\hat{\boldsymbol{S}} u(x,t;v) = u(x,t;-v),$$

must be destroyed. These symmetries can be combinations of all possible shifts and reflections in t, x and u. We also should keep in mind that these symmetries should not change the sign of the topological charge (3) in order to avoid transformations from a kink to an antikink (or vice versa). For the unperturbed SG equation (1) there are only two such operations:

$$\hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{X}}}: \; x \to -x, \quad t \to t + T/2, \quad u \to -u + 2\pi, \qquad \hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{T}}}: \; t \to -t + 2t_0.$$

The parameter t_0 is defined by the shape of the function $E(t)$. If the perturbation is added as written in equation (5), the time-reversal symmetry $\hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{T}}}$ is destroyed due to damping. Thus, the only symmetry left is the $\hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{X}}}$ symmetry. The SG equation will be invariant under this symmetry if the driving fields satisfy the following condition:

$$E(t + T/2) = -E(t). \tag{6}$$

It is easy to see that if $E(t) = E(t+T)$ and $\langle E(t)\rangle_t = 0$, the only way to change the sign of the function $E(t)$ is to shift it by $T/2$. In the *underdamped* limit $\alpha = 0$ the equation of motion is also invariant under the time reversal symmetry $\hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{T}}}$ if

$$E(t + t_0) = E(-t + t_0). \tag{7}$$

Thus, in order to achieve directed soliton propagation, one must apply the driving field $E(t)$ that violates the condition of equation (6) in the general dissipative case ($\alpha \neq 0$) and in the non-dissipative case ($\alpha = 0$) both (6) and (7) should be violated.

It has been shown in [8] that equation (5) with the single harmonic drive [$E(t) = E_0 \cos(\omega t + \theta_0)$] does not yield propagating kinks if the the driving amplitude is small enough. Kinks can propagate either if damping is very weak (see [8]) or when the driving amplitude exceeds certain threshold and the driving frequency is close to the resonance with the phonons $\omega \sim 1$ (see [9]). But in both cases this motion is not *directed*: kinks can move in either direction and proper averaging with respect to the initial phase will yield zero average kink velocity. For our problem we choose the driving field in the following form:

$$E(t) = E_1 \cos \omega t + E_2 \cos (m\omega t + \theta). \tag{8}$$

For this choice condition (6) is violated for any θ if $E_1, E_2 \neq 0$ and m is even, and is not violated for any E_1, E_2 and θ if m is odd. Also, condition (7) is violated if $\theta \neq 0, \pm\pi$ and $E_1, E_2 \neq 0$.

2.1 Perturbation theory

In order to get an idea how the driving field (8) affects the soliton dynamics, we use the soliton perturbation theory (see [10, 8] for details). The first order of the perturbation theory takes an advantage of the particle properties of the SG kink. It is assumed that perturbation $\epsilon f(t)$ of equation (5) is weak, so that the kink shape is not changed under the perturbation and its parameters change in time adiabatically. Therefore the initial problem can be mapped into the dynamics of the kink mass center coordinates ($X(t), v(t) \equiv \dot{X}(t)$), that can be introduced as $u(x,t) = 4\tan^{-1}(\exp\{[x - X(t)]/[1 - \dot{X}^2(t)]^{1/2}\})$. An ordinary differential equation for $X(t)$ can be obtained by differentiating the momentum (2) with respect to time, and using equation (5):

$$\dot{P} = -\alpha P + 2\pi E(t). \tag{9}$$

Assuming $P(t) = 8v(t)/\sqrt{1 - v(t)^2}$, equation (9) can be solved for $P(t)$, and eventually analytical expression of the average kink velocity $\langle v \rangle$, valid in the limit $E_j/\sqrt{\alpha^2 + (j\omega)^2} \ll 1$, $j = 1, 2$, can be obtained (see [7] for details) for $m = 2$:

$$\langle v \rangle = \frac{1}{T}\int_0^T v(\tau) d\tau \simeq \frac{3\pi^3 E_1^2 E_2 \sin(\theta - \theta_0)}{512(\alpha^2 + \omega^2)\sqrt{\alpha^2 + 4\omega^2}}, \qquad \tan\theta_0 = \frac{\alpha(\alpha^2 + 3\omega^2)}{2\omega^3}. \tag{10}$$

Similarly, for $m = 3$ we obtain that $\langle v \rangle = 0$ independently on θ and for an arbitrary initial phase. These results can be easily understood from the symmetry properties of $E(t)$. In the underdamped limit $\alpha \to 0$ we obtain $\theta_0 \to 0$, and, consequently $\langle v \rangle \sim \sin\theta$. Thus, directed soliton motion ceases to exist if $\theta = 0, \pm\pi$. This is not surprising since for these values of θ the driving field equals $E(t) = E_1 \cos(\omega t) \pm E_2 \cos(2\omega t)$ and the symmetry $\hat{\boldsymbol{S}}_{\boldsymbol{T}}$ is restored because $E(t) = E(-t)$.

2.2 Numerical simulations

In order to check the above considerations we have performed numerical simulations of the perturbed SG equation (5). In Fig. 1 the dynamics of a SG kink, initially at rest, driven by a bi-harmonic driver with $m = 2$ and by a single harmonic driver (i.e. $E_2 = 0$), are reported in Figs. 1(a,b), respectively (note that we use contour plots to show the time evolution surface generated by the kink profile). From these figures we see that, in the case $m = 2$ the soliton center of mass moves with a constant velocity, while for the single harmonic driver, it oscillates around the initial position. Numerical results of [7] show that an antikink with parameters as in Fig. 1a will move in the opposite direction.

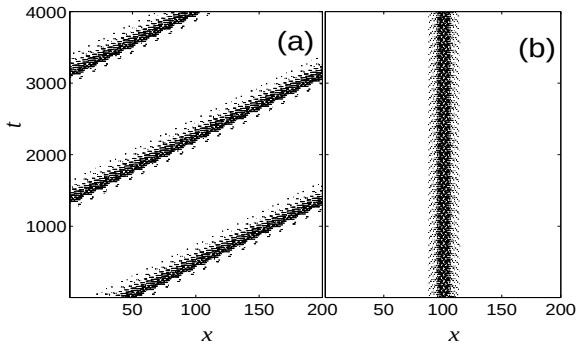

Figure 1. Contour plots of the velocity field $u_x(x,t)$ for (a): $E_1 = 0.4$, $E_2 = 0.26$ and (b): $E_1 = 0.66$, $E_2 = 0$ under periodic boundary conditions. Other parameters are $\alpha = 0.12$, $\omega = 0.25$, $\theta = 1.61$.

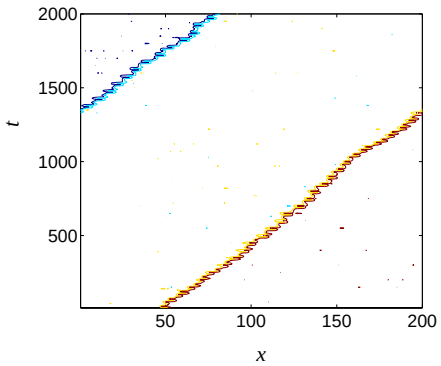

Figure 2. Contour plot for the displacement field $u(x,t)$ in the presence of white noise for parameters as in Fig. 1a.

Let us now briefly investigate the influence of a white noise on the kink dynamics. In order to accomplish this, we have simulated equation (5) with an additional stochastic term $\xi(x,t)$ which satisfies $\langle \xi(x,t) \rangle = 0$, $\langle \xi(x,t)\xi_m(x',t') \rangle = 2\alpha D\delta(x-x')\delta(t-t')$. In Fig. 2[1] we report the contour plot for the kink motion in the case of a bi-harmonic driver with $m = 2$. We see that the noise introduces disturbances on the profile but does not destroy the directed motion of the soliton. We checked that this property remains true also if we increase the amplitude of the noise up to the value when kink-antikink pairs start to nucleate. Moreover, the existence of the phenomena in presence of noise shows the validity of the above mechanism also for the non-deterministic soliton ratchets. Since the simulations with white noise can also be considered as "averaging" over the phase space, our simulations also have demonstrated that there is only one attractor of the system and the computed soliton velocity indeed can be considered and an average one. Similar simulations for $m = 3$ (see [7] for details) show that no directed motion of a kink is possible. This is because for $m = 3$ the $\hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{X}}}$ symmetry is not broken.

In Fig. 3 we show how the average kink velocity changes as a function of the phase difference between the driving fields, θ. Numerical results clearly confirm analytical approximation of the previous subsection (equation (10)). Another important observation is confirmation of the symmetry argument. As long as the underdamped limit is approached, the curve $\langle v \rangle(\theta)$ crosses the line $\langle v \rangle = 0$ closer and closer to the points $\theta = 0, \pm\pi$. This is in accordance with the fact that the symmetry $\hat{\boldsymbol{S}}_{\boldsymbol{\mathcal{T}}}$ is restored in this limit and (7) is no longer violated.

3 Discrete sine-Gordon equation

Discrete sine-Gordon (DSG) equation is a modification of its continuous counterpart for the media with spatial discreteness. It is used to model phenomena on lattices, for example fluxon

[1] Figures in colour will be available only in electronic version.

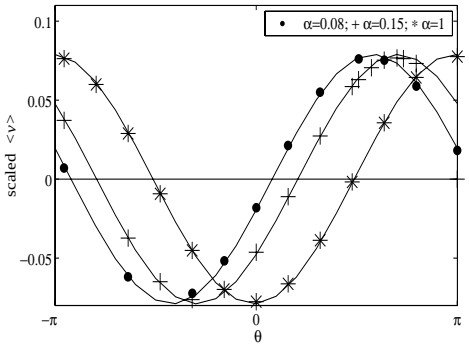

Figure 3. Scaled average kink velocity as a function of the phase difference θ for $E_1 = 0.3$, $E_2 = 0.195$, $\omega = 0.25$; $\alpha = 0.08$ ($\bullet$), $\alpha = 0.15$ ($+$) and $\alpha = 1$ ($*$). Solid lines are the best fit to the $A\sin(\theta + \theta_0)$ function.

dynamics in parallel Josephson junction arrays, dislocation motion in crystals, etc. The driven and damped DSG has the following form:

$$\ddot{u}_n + \alpha\dot{u}_n - \kappa(u_{n+1} - 2u_n + u_{n-1}) + \sin u_n + E(t) = 0, \qquad n = 1, 2, \ldots, N, \tag{11}$$

Here all the terms and parameters have the same meaning as in the SG counterpart. The parameter κ measures the discreteness of the system, in the limit $\kappa \to \infty$ the above equation reaches the continuum limit. One must mention that DSG is not integrable as compared to the continuous one and there is certain principal difference in its dynamics: kinks in this model cannot propagate with constant velocity (in the unperturbed limit, $\alpha = 0$, $E(t) = 0$). Kinks in DSG are pinned by the lattice (see [11] for details). Similarly to the case of the continuous sine-Gordon, two cases of boundary conditions can be considered: periodic $u_{n+N} = u_n + 2\pi$, $n = 1, 2, \ldots, N$ or free ends.

Discrete kink dynamics can be mapped (with a certain degree of approximation) into dynamics of a single particle. As shown by Braun and Kivshar in [11] this dynamics is described by the dynamics of the kink center $X(t)$: $u_n(t) = 4\arctan[\exp[n - X(t)]]$. Using this ansatz, the effective equation of motion for the kink center can be obtained:

$$\ddot{X} + \alpha\dot{X} + V'_{\rm PN}(X) + \tilde{E}(t) = 0, \qquad \tilde{E}(t) \sim E(t). \tag{12}$$

Here the Peierls–Nabarro (PN) potential $V_{\rm PN}(X) = V_{\rm PN}(X + 1)$, $V'_{\rm PN}(X) \sim \sin 2\pi X$, takes into account the discreteness of the lattice. Progressive kink motion is analogous to rotations of an AC-driven and damped pendulum. It will be locked to the frequency of the drive and will correspond to limit cycles of equation (12). The average kink velocity thus can be expressed as:

$$\langle v\rangle = \langle\dot{X}(t)\rangle = (m/n)(\omega/2\pi), \qquad m, n \in \mathbb{Z}.$$

Here m corresponds to the number of sites which kink has traveled during the time $nT = 2\pi n/\omega$.

Similarly to the previous case of the continuous SG, in order to achieve directed kink motion, we should destroy all symmetries which relate solutions with opposite velocities. We can do this analysis on the basis of equation (12) and this brings us to the problem, solved some time ago (see papers [3,4]). Operations which change the sign of the velocity are either shift in space and reflection in time or shift in time and reflection is space. In the underdamped case $\alpha = 0$ there are two such symmetries

$$\hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{X}}}: \ t \to t + T/2, \quad X \to -X, \qquad \hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{T}}}: \ t \to -t + 2t_0.$$

Situation here is very similar to the continuous case. Equation (12) is invariant under the operation $\hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{X}}}$ always only if $E(t) = -E(t + T/2)$ is satisfied (along with $V_{\rm PN}(-X) = V_{\rm PN}(X)$

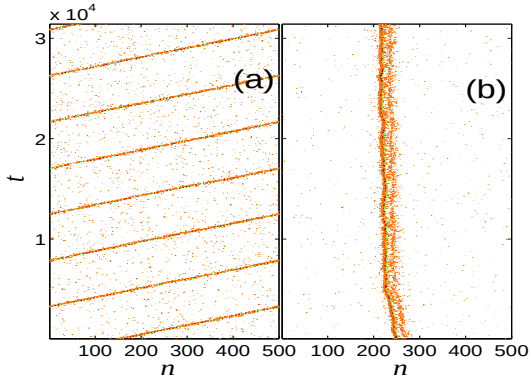

Figure 4. Numerical integration of equation (11) for (a) $E_1 = 0.3$, $E_2 = 0.15$ and (b) $E_1 = 0.45$, $E_2 = 0$. Other parameters are $\kappa = 1$, $\alpha = 0.05$, $\omega = 0.1$, $\theta = 2$. Periodic boundary conditions have been applied.

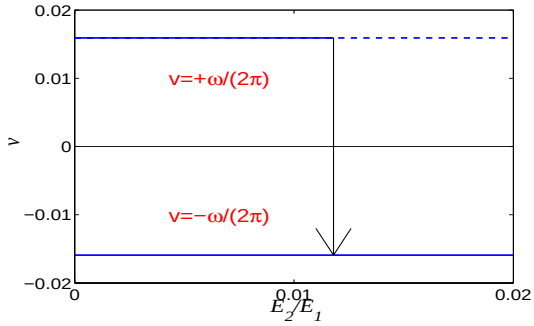

Figure 5. Velocities of two kinks, running into the opposite directions at $\alpha = 0.05$, $\omega = 0.1$, $E_1 = 0.21$, $\theta = 0$ as a function of E_2/E_1. Dashed line denotes that the given solution is no longer stable.

which is always satisfied because the sine-Gordon potential is symmetric). In the non-damping case is also invariant under $\hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{T}}}$ if $E(t + t_0) = E(-t + t_0)$. A new symmetry appears in the overdamped limit ($\alpha \to \infty$). In that case the equation of motion can be rewritten as $\dot{X} + V'_{\mathrm{PN}}(X) + \tilde{E}(t) = 0$. The symmetry can be written as follows:

$$\hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{T}}} : \; t \to -t + t_0, \quad X \to X + 1/2, \tag{13}$$

and equation (12) is invariant under this symmetry if

$$E(t + t_0) = -E(-t + t_0), \qquad V'_{\mathrm{PN}}(X) = -V'_{\mathrm{PN}}(X + 1/2). \tag{14}$$

If $V'_{\mathrm{PN}}(X) \sim \sin 2\pi X$ the second condition is satisfied. Thus, in the overdamped case both (6) and (14) must be violated if we want to obtain directed kink motion.

3.1 Numerical simulations

Verification of the above considerations has been performed via numerical integration of the DSG equation (11) in the presence of weak noise (similarly as in the previous section for the continuous SG) by adding an stochastic term $\xi_n(t)$ $[\langle \xi_n(t) \rangle = 0$, $\langle \xi_n(t)\xi_m(t') \rangle = 2\alpha D \delta_{mn} \delta(t - t')]$ to each of equations (11). Results of simulations are shown in Fig. 4. We clearly observe directed motion of a kink in the case of two mixed harmonics and absence of such motion when the driving field $E(t)$ consists from only one harmonic. Motion of an antikink for the same parameters occurs in the opposite direction with the same absolute value of the average velocity.

Emergence of the directed kink motion is caused by desymmetrization of basins of attraction of two limit cycles with opposite velocities. For one-particle ratchets it has been shown in [3,12].

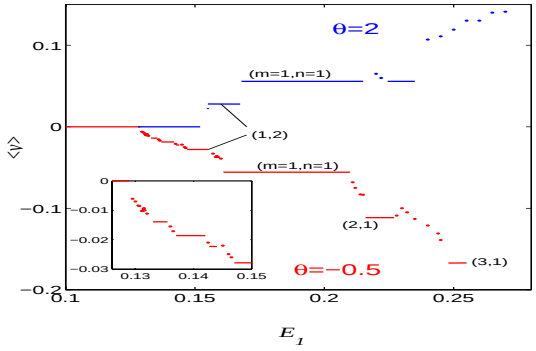

Figure 6. Kink velocity as a function of the driving amplitude $E_1 = E_2$ for $\theta = 2$ and $\theta = -0.5$. Other parameters are: $\omega = 0.35$, $\alpha = 0.1$, $\kappa = 1$. The inset shows more detailed picture for the $\theta = -0.5$ case.

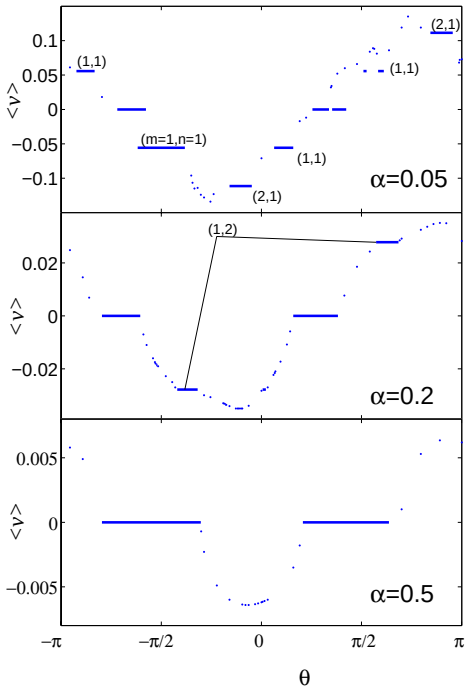

Figure 7. Average kink velocity as a function of the phase θ at $\omega = 0.35$, $E_1 = E_2 = 0.2$, and different values of damping: $\alpha = 0.05$ (upper panel),$\alpha = 0.2$ (middle panel) and $\alpha = 0.5$ (bottom panel).

As long as symmetry is broken (by switching to E_2), one of the basins of attraction begins to shrink and eventually disappears. Thus, only limit cycles which correspond to motion in one direction survive, as shown in Fig. 5. We see that already for rather weak desymmetrizations only one attractor survives.

In Fig. 6 we plot the kink velocity as a function of the driving amplitude. We observe certain differences compared to the case of continuous SG (see also [13] for details on damped DSG): a depinning threshold exists, while for the continuous case $\langle v \rangle \sim E_1^2 E_2$, e.g. kink can move for an arbitrarily small applied field. Since kink dynamics is locked to the driving frequency ω, the steps in the figure correspond to the rational multipliers of $\omega/(2\pi)$ and the dependence has a form of "devils staircases". After certain critical threshold $E_1 = E_2 \sim 0.3$ is passed, dynamics becomes chaotic and there is no kink solutions.

In Fig. 7 we plot average kink velocity as a function of the phase θ. Note that dependence of the kink velocity on the system parameters is no longer smooth. This is the result that dynamics is locked to the time-periodic driving field. Thus, the function $\langle v \rangle(\theta)$ only slightly resembles the

sine function, especially for strong dampings when depinning of the kink requires very strong fields. In the underdamped limit $\alpha \to 0$ directed motion disappears approximately at $\theta = 0, \pm\pi$, when $\hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{T}}}$ is restored: $E(t) = E(-t)$. Note that the same happens in the continuum case. In the overdamped limit $\alpha \to \infty$ directed motion disappears approximately at $\theta = \pm\pi/2$, when the symmetry $\hat{\boldsymbol{D}}_{\boldsymbol{\mathcal{I}}}$ is restored: $E(t) = E_1 \cos\omega t + E_2 \cos(2\omega t + \pi/2) = -E(\pi/\omega - t)$.

4 Conclusions

We have considered a way to produce a directed motion of a topological soliton (in both discrete and continuous media) in the presence of damping, using an appropriate AC driving force of zero mean. The effect has been demonstrated for both continuous and discrete SG equations, but can be extended to other kink-bearing models. We have shown that in order to get directed soliton propagation it is necessary to break certain symmetries of the driving field $E(t)$ and have confirmed our findings both analytically and numerically. The phenomenon can be observed experimentally in an AC biased annular long Josephson junction or annular 1D array of inductively coupled parallel small Josephson junctions.

Симетрія у нелінійній математичній фізиці // Праці Інституту математики НАН України. — Т. 50. — Ч. 2. — Київ: Інститут математики НАН України, 2004 / Ред.: А.Г. Нікітін, В.М. Бойко, Р.О. Попович, І.А. Єгорченко. — 504 с.

Цей том "Праць Інституту математики НАН України" є збірником статей учасників П'ятої міжнародної конференції "Симетрія у нелінійній математичній фізиці". Збірник складається з трьох частин, кожна з яких видана окремою книгою.

Дане видання є другою частиною і включає праці, присвячені суперсиметрії та застосуванню симетрійних методів у фізиці.

Розраховано на наукових працівників, аспірантів, які цікавляться новими тенденціями симетрійного аналізу та його застосувань.

Symmetry in Nonlinear Mathematical Physics // Proceedings of Institute of Mathematics of NAS of Ukraine. — V. 50. — Part 2. — Kyiv: Institute of Mathematics of NAS of Ukraine, 2004 / Editors: A.G. Nikitin, V.M. Boyko, R.O. Popovych, I.A. Yehorchenko. — 504 p.

This volume of the Proceedings of Institute of Mathematics of NAS of Ukraine includes papers of participants of the Fifth International Conference "Symmetry in Nonlinear Mathematical Physics". The collection consists of three parts which are published as separate issues.

This issue is the second part which contains papers devoted to supersymmetry and applications of symmetry methods in physics.

The book may be useful for researchers and post graduate students who are interested in modern trends in symmetry analysis and its applications.

We study the Nonlinear (Polynomial, N-fold, ...) SUSY algebra in one-dimensional QM. Its structure is determined by the type of conjugation operation (Hermitian conjugation or transposition) and described with the help of the Super-Hamiltonian projection on the zero-mode subspace of a supercharge. We show that the SUSY algebra with transposition symmetry is always polynomial in the Super-Hamiltonian if supercharges represent differential operators of finite order. The appearance of the extended SUSY with several supercharges is analyzed and it is established that no more than two independent supercharges may generate a nonlinear superalgebra. In the case with two independent supercharges we find a nontrivial hidden symmetry operator. It is revealed that wave functions of all Super-Hamiltonian bound states or, in the case of Super-Hamiltonian with periodic potential(s), all periodic wave functions corresponding to boundaries between allowed and forbidden energy bands are zero-modes of the hidden symmetry operator.

1 Introduction

In our report we consider the following topics: (i) Nonlinear SUSY algebras [1–3] with Hermitian conjugation and transposition symmetries of supercharges, (ii) extended SUSY algebra and appearance of antisymmetric symmetry operator (hidden symmetry operator), (iii) "strip-off" problem, (iv) (in)dependence of supercharges, maximal number of coexisting independent supercharges and optimal basis of supercharges, and (v) example: two independent supercharges of 2nd and 1st orders. The new (with respect to [4]) result presented in the paper is a description of properties of antisymmetric symmetry operator for a Hamiltonian with periodic potential. The proofs of presented results and a more complete list of references can be found in [4].

2 Four types of SUSY algebras with complex supercharges

Let h^+ and h^- be components of the matrix one-dimensional Schrödinger operator, a Super-Hamiltonian,

$$H = \begin{pmatrix} h^+ & 0 \\ 0 & h^- \end{pmatrix} = \begin{pmatrix} -\partial^2 + V_1(x) & 0 \\ 0 & -\partial^2 + V_2(x) \end{pmatrix} \equiv -\partial^2 \boldsymbol{I} + \boldsymbol{V}(x),$$

where $\partial \equiv d/dx$. The isospectral connection between Hamiltonians h^+ and h^- is provided by intertwining relations with the help of Crum–Darboux differential operators $q_N^\pm$,

$$h^+ q_N^+ = q_N^+ h^-, \qquad q_N^- h^+ = h^- q_N^-, \qquad q_N^\pm = \sum_{k=0}^{N} w_k^\pm(x)\partial^k, \qquad w_N^\pm = \text{const} \equiv (\mp 1)^N, \quad (1)$$

which, in the framework of SUSY QM, are components of the supercharges,

$$Q = \begin{pmatrix} 0 & q_N^+ \\ 0 & 0 \end{pmatrix}, \qquad \bar{Q} = \begin{pmatrix} 0 & 0 \\ q_N^- & 0 \end{pmatrix}, \qquad Q^2 = \bar{Q}^2 = 0, \qquad [H, Q] = [H, \bar{Q}] = 0.$$

According to known operator q_N^+ we can choose as q_N^- both $(q_N^+)^t$ and $(q_N^+)^\dagger$ and *vice versa*, where ^{t} and † denote transposition and Hermitian conjugation respectively. Thus, if coefficients of q_N^+ are real then we have unique $q_N^- = (q_N^+)^t = (q_N^+)^\dagger$, but if coefficients of q_N^+ are not real then we have two different q_N^- type operators, $(q_N^+)^t$ and $(q_N^+)^\dagger$. Hence, we have in general four different supercharges

$$Q, \qquad \bar{Q} = Q^t, \qquad \bar{Q}_c = Q^\dagger, \qquad Q_c = \bar{Q}_c^t,$$

pairs of which generates four SUSY algebras:

$$\mathcal{A}_1 \longleftrightarrow (\bar{Q}_c, Q), \qquad \mathcal{A}_2 \longleftrightarrow (\bar{Q}, Q), \qquad \mathcal{A}_3 \longleftrightarrow (\bar{Q}_c, Q_c), \qquad \mathcal{A}_4 \longleftrightarrow (\bar{Q}, Q_c).$$

Certain properties of $\mathcal{A}_{1,4}$ type complex SUSY algebras were considered in [2].

3 Superalgebras with transposition symmetry

The structure of SUSY algebras with real coefficient functions as well as the structure of the $\mathcal{A}_{2,3}$ type complex SUSY algebras is described by the following theorem.

Theorem 1 (on SUSY algebras with T-symmetry). *Let us introduce two sets of N linearly independent functions $\phi_n^\pm(x)$ $(n = 1, \ldots, N)$ which represent complete sets of zero-modes of the supercharge components* (1)*,*

$$q_N^\pm \phi_n^\pm = 0, \qquad q_N^- = (q_N^+)^t.$$

Then[1]*:*

1) *the Hamiltonians $h^\pm$ have finite matrix representations when acting on the set of functions $\phi_n^\pm(x)$,*

$$h^\pm \phi_n^\mp = \sum_m S_{nm}^\pm \phi_m^\mp,$$

2) *the SUSY algebra closure with $\bar{Q} = Q^t$ takes the polynomial form,*

$$\{Q, Q^t\} = \det\left[E\boldsymbol{I} - \boldsymbol{S}^+\right]_{E=H} = \det\left[E\boldsymbol{I} - \boldsymbol{S}^-\right]_{E=H} \equiv \mathcal{P}_N(H), \tag{2}$$

irrespectively on whether the Q type supercharge of order N is unique or there exist several such supercharges for a given Super-Hamiltonian H.

Corollary 1. *From* (2) *it is evident that eigenvalues of $\boldsymbol{S}^+$ and $\boldsymbol{S}^-$ and their corresponding degeneracies coincide.*

4 Several supercharges and appearance of symmetry operators

Let us now examine the case when for the Super-Hamiltonian H there are two different supercharges K and P of the type Q and of the orders N and N_1 respectively,

$$K = \begin{pmatrix} 0 & k_N^+ \\ 0 & 0 \end{pmatrix}, \qquad P = \begin{pmatrix} 0 & p_{N_1}^+ \\ 0 & 0 \end{pmatrix}, \tag{3}$$

where k_N^+ and $p_{N_1}^+$ have real coefficient functions and $N > N_1$. In particular, in the case when complex supercharge Q exists, we can choose K and P as $(Q + Q^*)/2$ and $(Q - Q^*)/(2i)$

[1]The first proposition is a necessary condition for the Hamiltonian system to be quasi-exactly solvable and it was investigated recently [5] within the notion of "conditional symmetry".

respectively, where * denotes complex conjugation of coefficient functions. Thus, each of supercharges K and P generates in our case a unique supercharge of type $\bar{Q}$:

$$\bar{K} = K^t = K^\dagger = \begin{pmatrix} 0 & 0 \\ k_N^- & 0 \end{pmatrix}, \qquad k_N^- = (k_N^+)^t,$$
$$\bar{P} = P^t = P^\dagger = \begin{pmatrix} 0 & 0 \\ p_{N_1}^- & 0 \end{pmatrix}, \qquad p_{N_1}^- = (p_{N_1}^+)^t.$$

The existence of two supercharges of type Q (*i.e.* K and P) conventionally implies the extension of SUSY algebra. To close the algebra one has to include all anticommutators between supercharges. Two supercharges K and P generate two Polynomial SUSY,

$$\left\{K, K^\dagger\right\} = \tilde{\mathcal{P}}_N(H), \qquad \left\{P, P^\dagger\right\} = \tilde{\mathcal{P}}_{N_1}(H),$$

which have to be embedded into a $\mathcal{N} = 2$ SUSY algebra. The closure of the extended, $\mathcal{N} = 2$ SUSY algebra is given by

$$\left\{P, K^\dagger\right\} \equiv \mathcal{R} = \begin{pmatrix} p_{N_1}^+ k_N^- & 0 \\ 0 & k_N^- p_{N_1}^+ \end{pmatrix}, \qquad \left\{K, P^\dagger\right\} \equiv \bar{\mathcal{R}} = \begin{pmatrix} k_N^+ p_{N_1}^- & 0 \\ 0 & p_{N_1}^- k_N^+ \end{pmatrix}.$$

Evidently the components of operators $\mathcal{R}$, $\bar{\mathcal{R}} = \mathcal{R}^\dagger = \mathcal{R}^t$ are differential operators of $N + N_1$ order commuting with the Hamiltonians $h^\pm$, hence they form symmetry operators $\mathcal{R}$, $\bar{\mathcal{R}}$ for the Super-Hamiltonian. However, in general, they are not polynomials of the Hamiltonians $h^\pm$ and these symmetries impose certain constraints on potentials.

Let us find the formal relation between the symmetry operators $\mathcal{R}$, $\bar{\mathcal{R}}$ and the Super-Hamiltonian. These operators can be decomposed into a Hermitian and an anti-Hermitian parts,

$$\mathcal{B} \equiv \frac{1}{2}(\mathcal{R} + \bar{\mathcal{R}}) \equiv \begin{pmatrix} b^+ & 0 \\ 0 & b^- \end{pmatrix}, \qquad i\mathcal{E} \equiv \frac{1}{2}(\mathcal{R} - \bar{\mathcal{R}}) \equiv i \begin{pmatrix} e^+ & 0 \\ 0 & e^- \end{pmatrix}.$$

It can be shown that the Hermitian operator $\mathcal{B}$ is a polynomial of the Super-Hamiltonian of the order $N_b \leq [(N+N_1)/2] \leq N-1$. The second Hermitian symmetry operator $\mathcal{E}$ is antisymmetric, $\mathcal{E}^t = -\mathcal{E}$. Hence, if $\mathcal{E}$ does not vanish identically it is a differential operator of *odd* order and cannot be realized by a polynomial of H. But at the same time

$$\mathcal{E}^2(H) \equiv \frac{1}{4}\left[2(\mathcal{R}\bar{\mathcal{R}} + \bar{\mathcal{R}}\mathcal{R}) - (\mathcal{R} + \bar{\mathcal{R}})^2\right] = \tilde{\mathcal{P}}_N(H)\tilde{\mathcal{P}}_{N_1}(H) - \mathcal{B}^2(H) \equiv \mathcal{P}_e(H) \tag{4}$$

is polynomial of H. Thus the nontrivial operator $\mathcal{E}(H)$ is a non-polynomial function of H — square root of equation (4) in an operator sense.

Closures of SUSY algebras $\mathcal{A}_1$–$\mathcal{A}_4$ can be written in terms of notation relating to real supercharges $K = (Q + Q^*)/2$ and $P = (Q - Q^*)/(2i)$ in the following form:

$$\mathcal{A}_1: \ \{Q, \bar{Q}_c\} = \tilde{\mathcal{P}}_N(H) + \tilde{\mathcal{P}}_{N_1}(H) - 2\mathcal{E}(H),$$
$$\mathcal{A}_2: \ \{Q, \bar{Q}\} = \tilde{\mathcal{P}}_N(H) - \tilde{\mathcal{P}}_{N_1}(H) + i2\mathcal{B}(H),$$
$$\mathcal{A}_3: \ \{Q_c, \bar{Q}_c\} = \tilde{\mathcal{P}}_N(H) - \tilde{\mathcal{P}}_{N_1}(H) - i2\mathcal{B}(H),$$
$$\mathcal{A}_4: \ \{Q_c, \bar{Q}\} = \tilde{\mathcal{P}}_N(H) + \tilde{\mathcal{P}}_{N_1}(H) + 2\mathcal{E}(H),$$
$$\bar{Q}_c = Q^\dagger = K^\dagger - iP^\dagger, \qquad Q_c = Q^* = K - iP, \qquad \bar{Q} = Q^t = K^\dagger + iP^\dagger.$$

One can show that components of $\mathcal{E}(H)$ have the following important properties.

1. In the case when $h^\pm$ has bound states, wave functions $\Psi_i^\pm$ of all these states are zero-modes of $e^\pm(h^\pm)$ and corresponding energies $E_i^\pm$ are roots of the polynomial $\mathcal{P}_e(E)$:

$$e^\pm(h^\pm)\Psi_i^\pm = e^\pm(E_i^\pm)\Psi_i^\pm = 0, \qquad \mathcal{P}_e(E_i^\pm) = 0. \tag{5}$$

Among solutions of (5) one reveals also a zero-energy state at the bottom of continuum spectrum.

2. In the case, when the potential of $h^{\pm}$ is periodic, all boundaries between allowed and forbidden energy bands $E_i^{\pm}$ are roots of $\mathcal{P}_e(E)$ and corresponding to these boundaries periodic wave functions $\Psi_i^{\pm}$ are zero-modes of $e^{\pm}(h^{\pm})$ (see (5) again).

Thus (5) represents an algebraic equation on bound state energies or on energy-band boundaries of a system possessing two supersymmetries. On the other hand one could find also the solutions of (5) which are not associated to any bound state or to any energy-band boundary. The very appearance of such unphysical solutions is accounted for by the trivial possibility to replicate supercharges by their multiplication on the polynomials of the Super-Hamiltonian and it is discussed below.

5 "Strip-off" problem

The pair of two supersymmetries analyzed before may rigidly determine the class of potentials $V_{1,2}$ contracting the freedom in their choice from a functional one to a parametric one. On the other hand, there exists a trivial possibility when the intertwining operators $k_N^{\pm}$ and $p_{N_1}^{\pm}$ are related by a factor depending on the Hamiltonian,

$$k_N^{\pm} = F(h^{\pm})p_{N_1}^{\pm} = p_{N_1}^{\pm}F(h^{\mp}),$$

where $F(x)$ is assumed to be a polynomial. Obviously in this case the symmetry operator $\mathcal{E}(H)$ identically vanishes and the appearance of the second supercharge does not result in any restrictions on potentials.

More generally the orders of polynomial superalgebras and some of the roots of associated polynomials may not be involved in determination of the structure of the potentials. In particular, let the operators $k_N^{\pm}$ and $p_{N_1}^{\pm}$ be reducible to some lower-order ones $\tilde{k}_{\tilde{N}}^{\pm}$ and $\tilde{p}_{\tilde{N}_1}^{\pm}$,

$$k_N^{\pm} = F_k(h^{\pm})\tilde{k}_{\tilde{N}}^{\pm} = \tilde{k}_{\tilde{N}}^{\pm}F_k(h^{\mp}), \qquad p_{N_1}^{\pm} = F_p(h^{\pm})\tilde{p}_{\tilde{N}_1}^{\pm} = \tilde{p}_{\tilde{N}_1}^{\pm}F_p(h^{\mp}), \tag{6}$$

where $F_k(y)$ and $F_p(y)$ are polynomials. Then evidently the superalgebra generated by $\tilde{k}_{\tilde{N}}^{\pm}$ and $\tilde{p}_{\tilde{N}_1}^{\pm}$ equally well characterizes the Super-Hamiltonian system with the same potentials.

Thus, we have come to the problem of how to discern the nontrivial part of a supercharge and avoid multiple SUSY algebras generated by means of "dressing" (6). It can be systematically performed with the help of the following theorem.

Theorem 2 ("strip-off" theorem). *Let us admit the construction of the Theorem on SUSY algebras with T-symmetry. Then the requirement that Jordan form of the matrix $\boldsymbol{S}^-$ (or $\boldsymbol{S}^+$) contains n pairs (and no more) of Jordan cells with equal eigenvalues λ_l and the sizes ν_l of a smallest cell in the l-th pair is necessary and sufficient to ensure for the intertwining operator q_N^+ (or q_N^-) to be represented in the factorized form:*

$$q_N^{\pm} = \tilde{q}_{\tilde{N}}^{\pm}\prod_{l=1}^{n}(\lambda_l - h^{\mp})^{\nu_l},$$

where $\tilde{q}_{\tilde{N}}^{\pm}$ are intertwining operators of order $\tilde{N} = N - 2\sum_{l=1}^{n}\nu_l$ which cannot be decomposed further on in the product similar to (6) *with $F_q(x) \neq \text{const}$.*

Corollary 2. *Jordan forms of $\boldsymbol{S}^+$ and $\boldsymbol{S}^-$ are identical up to transposition of certain cells.*

6 Optimization of supercharges

Still the stripped-off supercharges $k_N^{\pm}$ and $p_{N_1}^{\pm}$ do not necessarily represent an optimal set of them and provide an optimal structure of the symmetry operator $\mathcal{E}(H)$. Let us illustrate it with the help of the following example. One can show that there is the case when intertwining operators of both pairs $k_N^{\pm}$, $p_{N_1}^{\pm}$ and $t^{\pm} \equiv p_{N_1}^{\pm} k_N^{\mp} p_{N_1}^{\pm}$, $p_{N_1}^{\pm}$ cannot be stripped-off, but at the same time the latter pair is evidently more complex than the former. In addition, the composed of $t^{\pm}$ and $p_{N_1}^{\pm}$ symmetry operator $\mathcal{E}_t(H)$ with components,

$$e_t^{\pm} = \pm i\frac{1}{2}(t^{\pm}p_{N_1}^{\mp} - p_{N_1}^{\pm}t^{\mp}) = \mp i\frac{1}{2}(k_N^{\pm}p_{N_1}^{\mp} - p_{N_1}^{\pm}k_N^{\mp})p_{N_1}^{\pm}p_{N_1}^{\mp} = -e^{\pm}\tilde{\mathcal{P}}_{N_1}(h^{\pm})$$

is not optimal because of the superfluous polynomial factor $\tilde{\mathcal{P}}_{N_1}(H)$.

Thus, if there are several SUSY generators we have not only such fundamental problems as (i) to introduce the notion of (in)dependence of intertwining operators and (ii) to find out how many independent intertwining operators can coexist, but also and the problem (iii) to define an optimal basis of intertwining operators.

Let us define the intertwining operators $q_i^{\pm}$, $i = 1, \ldots, n$ to be dependent if and only if the polynomials $\alpha_i^{\pm}(y)$ exist such that not all of them are vanishing and

$$\sum_{i=1}^{n} \alpha_i^{\pm}(h^{\pm}) q_i^{\pm} = 0. \tag{7}$$

If the relation (7) results in $\alpha_i^{\pm}(y) = 0$ for all i the corresponding SUSY generators are independent. Evidently the (in)dependence of q_i^{+} entails the (in)dependence of q_i^{-} and *vice versa*.

The following theorem plays a key role in resolution of how many independent supercharges can commute with a given Super-Hamiltonian.

Theorem 3 (on (in)dependence of supercharges). *Consider two non-trivial intertwining operators $q_i^{\pm}$, $i = 1, 2$ with transposition symmetry $q_i^{+} = (q_i^{-})^t$ which in general may have complex coefficients and let us normalize them in accordance to* (1)*. Then the stripped-off intertwining operators $\tilde{q}_i^{\pm}$ coincide if and only if the symmetry operator made of $q_i^{\pm}$ vanishes, $q_1^{+}q_2^{-} - q_2^{+}q_1^{-} = 0$ (or equivalently $q_1^{-}q_2^{+} - q_2^{-}q_1^{+} = 0$).*

With the help of this Theorem one can show the following:

a) any symmetric (self-transposed) symmetry operator $B^{\pm} = (B^{\pm})^t$, $B^{\pm}h^{\pm} = h^{\pm}B^{\pm}$ is a polynomial of the Hamiltonian $h^{\pm}$;

b) any two antisymmetric symmetry operators $e_i^{\pm} = -(e_i^{\pm})^t$, $e_i^{\pm}h^{\pm} = h^{\pm}e_i^{\pm}$, $i = 1, 2$ are dependent, *i.e.* being stripped off coincide;

c) the maximal number of independent intertwining operators is two.

Using the fact that maximal number of independent intertwining operators is two, one can show the next.

1. In the case when any two intertwining operators are dependent, every intertwining operator q^{+} can be represented in the form

$$q^{+} = \alpha_q(h^{+})p^{+},$$

where $\alpha_q(y)$ is polynomial and p^{+} is normalized intertwining operator of minimal order. It is evident that p^{+} is unique and real.

2. In the case when there are two independent intertwining operators, every intertwining operator q^{+} can be represented in the form

$$q^{+} = \alpha_q(h^{+})p^{+} + \beta_q(h^{+})k^{+},$$

where $\alpha_q(y)$ and $\beta_q(y)$ are polynomials, p^+ is normalized intertwining operator of minimal order and k^+ is independent of p^+ normalized intertwining operator of minimal order. It is evident that p^+ is unique and real and that k^+ can be chosen with real coefficients. It can be shown that sum of orders of p^+ and k^+ is odd.

Thus the set of p^+ and k^+ (or only p^+ in the case 1) form an optimal basis of intertwining operators. As all $q^- = (q^+)^t$ the same results are translated to the set of $p^- = (p^+)^t$ and $k^- = (k^+)^t$.

7 Example: $N = 2$, $N_1 = 1$

Let us examine the algebraic structure of the simplest non-linear SUSY with two supercharges K of the 2nd order and P of the 1st order. The supersymmetries generated by K, $\bar{K}$ and P, $\bar{P}$ with components

$$k_2^{\pm} \equiv \partial^2 \mp 2f(x)\partial + \tilde{b}(x) \mp f'(x), \qquad p_1^{\pm} \equiv \mp\partial + \chi(x)$$

prescribe that

$$V_{1,2} = \chi^2 \mp \chi' = \mp 2f' + f^2 + \frac{f''}{2f} - \left(\frac{f'}{2f}\right)^2 - \frac{d}{4f^2} - a, \qquad \tilde{b} = f^2 - \frac{f''}{2f} + \left(\frac{f'}{2f}\right)^2 + \frac{d}{4f^2},$$

where χ, f are real functions and a, d are real constants. The related superalgebra closure for K, $\bar{K}$ and P, $\bar{P}$ takes the form,

$$\{K, K^\dagger\} = (H + a)^2 + d, \qquad \{P, P^\dagger\} = H,$$

the latter one clarifies the role of constants a, d.

The compatibility of two supersymmetries is achieved on solutions of the following equations

$$\chi = 2f + \chi_0, \qquad f^2 + \frac{f''}{2f} - \left(\frac{f'}{2f}\right)^2 - \frac{d}{4f^2} - a = \chi^2 = (2f + \chi_0)^2, \tag{8}$$

where χ_0 is an arbitrary real constant. The latter one represents a nonlinear second-order differential equation which solutions are parameterized by two integration constants. Therefore as it was advertised the existence of two SUSY constrains substantially the class of potentials for which they may hold.

Let us use the freedom to redefine the higher-order supercharge $k_2^{\pm} \to k_2^{\pm} + \chi_0 p_1^{\pm}$ for eliminating the constant χ_0 in (8). After this simplification the equation (8) is integrated into the following, first-order one,

$$\chi = 2f, \qquad (f')^2 = 4f^4 + 4af^2 + 4G_0 f - d \equiv \Phi_4(f),$$

where G_0 is a real constant.

The solutions of this equation are elliptic functions which can be easily found in the implicit form,

$$\int_{f_0}^{f(x)} \frac{df}{\sqrt{\Phi_4(f)}} = \pm(x - x_0),$$

where the lower limit of integration f_0 and x_0 are real constants.

It can be shown that they may be nonsingular in three situations.

a) The polynomial $\Phi_4(f)$ has four different real roots $f_1 < f_2 < f_3 < f_4$ and f_0 is chosen between f_2 and f_3. The corresponding potentials are periodic. This case will not be examined here.

b) $\Phi_4(f)$ has three different real roots and the double root $\beta/2$ is either the maximal one or a minimal one,

$$\Phi_4(f) = 4\left(f - \frac{\beta}{2}\right)^2 \left[\left(f + \frac{\beta}{2}\right)^2 - (\beta^2 - \epsilon)\right], \qquad 0 < \epsilon < \beta^2. \tag{9}$$

Then there exists a relation between constants a, d, G_0 in terms of parameters β, ϵ,

$$a = \epsilon - \frac{3\beta^2}{2} < 0, \qquad G_0 = \beta(\beta^2 - \epsilon), \qquad d = \beta^2\left(\frac{3\beta^2}{4} - \epsilon\right). \tag{10}$$

Besides, the constant f_0 is taken between the double root and a nearest simple root.

c) $\Phi_4(f)$ has two different real double roots which correspond in (9), (10) to $G_0 = 0$, $\beta^2 = \epsilon > 0$, $a = -\beta^2/2$, $d = -\beta^4/4$. The constant f_0 is taken between the roots.

The corresponding potentials $V_{1,2}$ are well known and in the cases b) and c) are reflectionless, with one bound state at the energy $E_b = (\beta^2 - \epsilon)$ and with the continuum spectrum starting from $E_c = \beta^2$. In particular, in the case b) the potentials coincide in their form and differ only by shift in the coordinate (about the latter phenomenon see [6]),

$$V_{1,2} = \beta^2 - \frac{2\epsilon}{\mathrm{ch}^2\left(\sqrt{\epsilon}(x - x_0^{(1,2)})\right)}, \qquad x^{(1,2)} = x_0 \pm \frac{1}{4\sqrt{\epsilon}} \ln\frac{\beta - \sqrt{\epsilon}}{\beta + \sqrt{\epsilon}},$$

and in the case c) one of the potentials can be chosen constant,

$$V_1 = \beta^2, \qquad V_2 = \beta^2\left(1 - \frac{2}{\mathrm{ch}^2\left(\beta(x - x_0)\right)}\right).$$

For these potentials one can illustrate all the relations of extended SUSY algebra. Thus, in particular, the polynomial symmetry operator $\mathcal{B}(H)$ turns out to be constant, $\mathcal{B}(H) = G_0$, the second symmetry operator reads,

$$\mathcal{E}(H) = i\left[\boldsymbol{I}\,\partial^3 - \left(a\boldsymbol{I} + \frac{3}{2}\boldsymbol{V}(x)\right)\partial - \frac{3}{4}\boldsymbol{V}'(x)\right]$$

and, finally, $\mathcal{E}^2(H)$ takes the form

$$\mathcal{E}^2(H) \equiv \mathcal{P}_e(H) = H\left[(H + a)^2 + d\right] - G_0^2 \equiv (H - E_b)^2(H - E_c).$$

Hence, in considered case both roots of $\mathcal{P}_e(E)$ characterize spectrum of H: one of them (E_b) characterizes the energy of a bound state and another (E_c) characterizes the energy of a state in the bottom of continuum spectrum.

8 More about symmetry operators

Let us suppose that:

a) the Hamiltonian h_0 commutes with an antisymmetric real operator R_0 of order $2n + 1$ which cannot be stripped off;

b) h_0 has n bound states with wave functions Ψ_l and energies E_l, $l = 0, \ldots, n - 1$, where $E_{l+1} > E_l$, $l = 0, \ldots, n - 2$.

Then one can show that:

a) the (normalized) symmetry operator R_0 can be factorized in the form,

$$R_0 = r_0^t \cdots r_{n-1}^t\, \partial\, r_{n-1} \cdots r_0, \qquad r_l \equiv \partial + \chi_l, \tag{11}$$

with non-singular real superpotentials χ_l such that

$$r_l \cdots r_0 \Psi_l = 0, \qquad l = 0, \ldots, n-1;$$

b) the ladder (dressing chain) relations hold,

$$h_{l+1} r_l = r_l h_l, \qquad l = 0, \ldots, n-1,$$
$$h_l \equiv r_{l-1} r_{l-1}^t + E_{l-1} = r_l^t r_l + E_l, \qquad l = 1, \ldots, n-1,$$
$$h_0 = r_0^t r_0 + E_0, \qquad h_n = r_{n-1} r_{n-1}^t + E_{n-1};$$

c) the antisymmetric symmetry operators arise for each intermediate Hamiltonian,

$$R_l = r_l^t \cdots r_{n-1}^t \, \partial \, r_{n-1} \cdots r_l, \qquad R_n = \partial, \qquad R_l h_l = h_l R_l, \qquad l = 0, \ldots, n.$$

Evidently the Hamiltonian h_n describes a free particle and therefore the Hamiltonian h_0 is intertwined with the Hamiltonian of free particle.

The described result can be illustrated with the help of the case b) of Section 7, where each component of the symmetry operator $\mathcal{E}(H)$ can be represented in the canonical factorized form (11),

$$e^{\pm} = i \left[\partial^3 - \left(a + \frac{3}{2} V_{1,2} \right) \partial - \frac{3}{4} V_{1,2}' \right] = -i \left(-\partial - \frac{\Psi_{01,2}'}{\Psi_{01,2}} \right) \partial \left(\partial - \frac{\Psi_{01,2}'}{\Psi_{01,2}} \right),$$

by means of the bound-state wave functions, $\Psi_{01,2} = C\sqrt{V_{1,2} - \beta^2}$.

D-branes on Calabi–Yau Hypersurfaces

Ivan M. BURBAN

Bogolyubov Institute for Theoretical Physics, 14b Metrologichna Str., 03143 Kyiv, Ukraine
E-mail: *mmtpitp@bitp.kiev.ua*

The construction of BPS D-branes of the type IIB superstring theory on two- and three-parameter elliptic and $K3$ fibered Calabi–Yau hypersurfaces is discussed. The explicit maps between the characteristic classes of the Chan–Paton fiber bundle and the D-brane charges is established.

1 Introduction

In this note we study the description of BPS D-branes of the type IIB superstring theory compactified on Calabi–Yau manifolds. It is well know that superstring theory is not only theory of superstrings but also another of extended objects, D-branes, which although are not perturbative string states themselves but allow description in the perturbative string theory.

In spite of significant progress in the study of D-branes on the curved space-time spaces, in particular, on Calabi–Yau manifolds, situation is far from being understood. In the arsenal of the theoretical physics there is a number of simple Calabi–Yau manifolds, which are convenient for studying superstring theories and their D-branes. In this note we consider D-branes on the Calabi–Yau hypersurfaces of weighted projective spaces with two- and three-parameter Kähler moduli spaces. These surfaces have orbifold singularities. After resolving these singularities the hypersurfaces exhibit structures of fibered Calabi–Yau manifolds. It helps us to make the description of D-branes on these manifolds in more detail. The analysis of string dualities in four space-time dimensions requires to research D-branes wrapped on supersymmetric cycles of compactifying manifold. The study of boundary states of D-branes wrapped around of supersymmetric cycles in the quintic hypersurface of four dimension projective space was done in [1]. The detailed information on a part of spectrum of the D-branes on Calabi–Yau manifold in the geometric phase was presented in [2]. In [3] the relevant aspects were extended to some other models.

2 Weighted projective spaces

We consider weighted projective spaces $P^4_{(k_1,k_2,k_3,k_4,k_5)}$ with weights (k_1,k_2,k_3,k_4,k_5) described in five complex "homogeneous coordinates" (z_1,z_2,z_3,z_4,z_5) not all of them vanishing, which are subject to identification

$$(z_1,z_2,z_3,z_4,z_5)\simeq\left(\lambda^{k_1}z_1,\lambda^{k_2}z_2,\lambda^{k_3}z_3,\lambda^{k_4}z_4,\lambda^{k_5}z_5\right) \tag{1}$$

for nonzero λ. Thus, a weighted projective space is a generalization of ordinary projective space and in this notation $P^4=P^4_{(1,1,1,1,1)}$. These spaces, except of $P^4_{(k_1,k_2,k_3,k_4,k_5)}=P^4_{(1,1,1,1,1)}$, have orbifold singularities due to the identification (1).

Indeed, if we put $z_i=(\zeta_i)^{k_i}$ then from relation (1) we obtain

$$(\zeta_1^{k_1},\zeta_2^{k_2},\zeta_3^{k_3},\zeta_4^{k_4},\zeta_5^{k_5})\simeq\left((\lambda\zeta_1)^{k_1},(\lambda\zeta_2)^{k_2},(\lambda\zeta_3)^{k_3},(\lambda\zeta_4)^{k_4},(\lambda\zeta_5)^{k_5}\right) \tag{2}$$

that is

$$\zeta_i^{k_i} \simeq (\lambda\zeta_i)^{k_i},$$

or

$$(\zeta_1,\zeta_2,\zeta_3,\zeta_4,\zeta_5) \simeq \lambda\,(\zeta_1,\zeta_2,\zeta_3,\zeta_4,\zeta_5)$$

and

$$(\zeta_1,\zeta_2,\zeta_3,\zeta_4,\zeta_5) \simeq \left(\zeta_1 e^{\frac{2\pi i}{k_1}},\zeta_2 e^{\frac{2\pi i}{k_2}},\zeta_3 e^{\frac{2\pi i}{k_3}},\zeta_4 e^{\frac{2\pi i}{k_4}},\zeta_5 e^{\frac{2\pi i}{k_5}}\right).$$

Therefore,

$$P^4_{(k_1,k_2,k_3,k_4,k_5)} = \frac{P^4_{(1,1,1,1,1)}}{Z_{k_1}\times Z_{k_2}\times Z_{k_3}\times Z_{k_4}\times Z_{k_5}}$$

and we have obtained a manifold $P^4_{(k_1,k_2,k_3,k_4,k_5)}[d], d = k_1+k_2+k_3+k_4+k_5$, with orbifold singularities.

We wish to study D-branes on the simplest Calabi–Yau hypersurfaces defined by polynomials on the homogeneous coordinates in weighted projective spaces.

The one-parameter Calabi–Yau hypersurfaces M [4] are given by

$$z_1^5+z_2^5+z_3^5+z_4^5+z_5^5=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{(1,1,1,1,1)}[5], \tag{3}$$

$$z_1^6+z_2^6+z_3^6+z_4^6+z_5^3=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{(1,1,1,1,2)}[6], \tag{4}$$

$$z_1^8+z_2^8+z_3^8+z_4^8+z_5^2=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{(1,1,1,1,4)}[8], \tag{5}$$

$$z_1^{10}+z_2^{10}+z_3^{10}+z_4^5+z_5^2=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{(1,1,1,2,5)}[10]. \tag{6}$$

In order to study the stringy geometry of these manifolds we consider one-parameter family of mirror manifolds W given by the Greene–Plesser orbifold construction $\{p_i=0\}/G_i$

$$z_1^5+z_2^5+z_3^5+z_4^5+z_5^5-5\psi z_1z_2z_3z_4z_5=0, \qquad G=Z_5\times Z_5, \tag{7}$$

$$z_1^6+z_2^6+z_3^6+z_4^6+z_5^3-6\psi z_1z_2z_3z_4z_5=0, \qquad G=Z_3\times Z_6^2, \tag{8}$$

$$z_1^8+z_2^8+z_3^8+z_4^8+z_5^2-8\psi z_1z_2z_3z_4z_5=0, \qquad G=Z_2\times Z_8^2, \tag{9}$$

$$z_1^{10}+z_2^{10}+z_3^{10}+z_4^5+z_5^2-10\psi z_1z_2z_3z_4z_5=0, \qquad G=Z_{10}^2. \tag{10}$$

The stringy geometry of the Calabi–Yau hypersurfaces M [5,6].

$$8z_1^8+z_2^8+z_3^4+z_4^4+z_5^4=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{(1,1,2,2,2)}, \tag{11}$$

$$z_1^{12}+z_2^{12}+z_3^6+z_4^6+z_5^2=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{1,1,2,2,6}, \tag{12}$$

$$z_1^{18}+z_2^{18}+z_3^{18}+z_4^3+z_5^2=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{1,1,1,6,9}. \tag{13}$$

are defined by the two-parameter families of the mirror manifolds W obtained by the Greene–Plesser orbifold construction $\{p_i=0\}/G_.$

$$z_1^8+z_2^8+z_3^4+z_4^4+z_5^4-8\psi z_1z_2z_3z_4z_5-2\phi z_1^4z_2^4=0, \qquad G=Z_4^3, \tag{14}$$

$$z_1^{12}+z_2^{12}+z_3^6+z_4^6+z_5^2-12\psi z_1z_2z_3z_4z_5-2\phi z_1^6z_2^6=0, \qquad G=Z_6^2\times Z_2, \tag{15}$$

$$z_1^{18}+z_2^{18}+z_3^{18}+z_4^3+z_5^2-18\psi z_1z_2z_3z_4z_5-3\phi x_1x_2x_3=0, \qquad G=Z_{18}. \tag{16}$$

The Calabi–Yau hypersurface M defined by the equation

$$z_1^{24}+z_2^{24}+z_3^{12}+z_4^3+z_5^2=0, \qquad (z_1:z_2:z_3:z_4:z_5)\in P^4_{(1,1,2,8,12)} \tag{17}$$

has its three-parameter mirror family of W obtained by the Greene–Pleser orbifold construction

$$z_1^{24}+z_2^{24}+z_3^{12}+z_4^3+z_5^2-12\psi_0 z_1z_2z_3z_4z_5 \\ -2\psi_1(z_3z_4z_5)^6-\psi_2(z_4z_5)^{12}=0, \qquad G=Z_6\times Z_{12}. \tag{18}$$

3 Classical geometry of elliptic and $K3$ fibrations

The hypersurface $P^4_{(1,1,1,6,9)}[18]$ has two divisors E and L, which generate $H_4(M,Z)$. The exceptional divisor E in M is generated by blowing up singular line $z_2 = z_3 = 0$, which intersects M in a single point. The divisor L is defined by first order polynomial in z_1, z_2 and z_3.

The two homology classes h, l generate homology group $H_2(M,Z)$. The elliptic fibration structure is induced by linear system $|L|$ which maps M to P^2. The generic fiber can be proved to be an elliptic curve. The homology class l is a hyperplane class of E.

The choice (E,L) as generators of the complexified Kähler cone leads to generic Kähler class $K = t_1E + t_2L$, where (t_1,t_2) are classical coordinates on Kähler moduli space of M.

The models $P^4_{(1,1,2,2,2)}[8]$ and $P^4_{(1,1.2,2,6)}[12]$ given by degree 8 and 12 hypersurfaces both at $z_1 = z_2 = 0$ have a curve C of singularities blowing up of which leads to exceptional divisor E in M. The second divisor class L of both models is $K3$ fiber of fibration of M over P^1, generated by a linear system $|L|$ which is generated by the degree one polynomials. The divisor classes E and L together generate $H^4(M,Z)$. In both models the degree two polynomials generate the linear system $|H| = |2L+E|$. The homology group $H_2(M,Z)$ is generated by the classes l and h, which are defined by $h = \frac{1}{4}H\cdot L$, $l = \frac{1}{4}H\cdot E$ for degree 8 model and $h = \frac{1}{2}H\cdot L$, $l = \frac{1}{2}H\cdot E$ for degree 12 model. The intersection relations for these models are

$$\begin{aligned}
&L^3 = 0, \qquad E\cdot h = 1,\\
&E^3 = 9, \qquad E^2\cdot L = -3, \qquad E\cdot L^2 = 1,\\
&h = L^2, \qquad l = E\cdot H\cdot L, \qquad E\cdot l = -2,
\end{aligned} \tag{19}$$

where $H = E + 3L$, for $P^4_{(1,1,1,6,9)}[18]$ hypersurface,

$$\begin{aligned}
&H^3 = 8, \qquad H^2\cdot L = 4, \qquad H\cdot L^2 = 0, \qquad L^3 = 0,\\
&E^3 = 16, \qquad E^2\cdot L = 4, \qquad E\cdot L^2 = 0, \qquad H\cdot E\cdot L = 4,\\
&h = 1/4H\cdot L, \qquad l = 1/4H\cdot E, \qquad H\cdot h = 1, \qquad E\cdot l = -2,\\
&L\cdot l = 1, \qquad L\cdot h = 0, \qquad H\cdot l = 0, \qquad E\cdot h = 1,\\
&c_2(M)\cdot E = 8, \qquad c_2(M)\cdot H = 56,
\end{aligned} \tag{20}$$

where $|H| = |2L + E|$, for $P^4_{(1,1,2,2,6)}[18]$ and

$$\begin{aligned}
&H^3 = 4, \qquad H^2\cdot L = 2, \qquad H\cdot L^2 = 0, \qquad L^3 = 0,\\
&E^3 = -8, \qquad E^2\cdot L = 2, \qquad E\cdot L^2 = 0, \qquad H\cdot E\cdot L = 2,\\
&h = 1/4H\cdot L, \qquad l = 1/4H\cdot E, \qquad H\cdot h = 1, \qquad E\cdot l = -2,\\
&L\cdot l = 1, \qquad L\cdot h = 0, \qquad H\cdot l = 0, \qquad E\cdot h = 1,\\
&c_2(M)\cdot E = 8, \qquad c_2(M)\cdot H = 56,
\end{aligned} \tag{21}$$

where $|H| = |2L + E|$, for $P^4_{(1,1,2,6,9)}[18]$ models. The choice (E,L) as generators of the complexified Kähler cone leads to generic Kähler class $K = t_1E + t_2L$, where (t_1,t_2) are classical coordinates on the Kähler moduli space of M.

4 D-branes and periods

In the points of large volume limit of Kähler moduli space we can relate the BPS charge lattice of the low energy effective theory (the integral symplectic lattice $H^3(W,Z)$ of the middle cohomology of mirror manifold W) with BPS charge lattice of microscopic D-brane charges (the integer

quadratic lattice $K(M)$ of K-theory of manifold M). An every vector $\boldsymbol{n} = (n_6, n_4^1, n_4^2, n_0, n_2^1, n_2^2)$ of middle cohomology $H^3(W, Z)$ of the mirror manifold W defines central charge

$$Z(\boldsymbol{n}) = n_6\Pi_1 + n_4^1\Pi_2 + n_4^2\Pi_3 + n_0\Pi_4 + n_2^1\Pi_5 + n_2^2\Pi_6. \tag{22}$$

On the other hand every element $\eta \in K(M)$ corresponding to topological invariant $\mathrm{ch}\,(\eta)$ defines the effective charge (the Mukai vector) of D-brane

$$Q = \mathrm{ch}\,(\eta)\sqrt{\mathrm{Td}\,(\mathcal{E})} \in H^0(M) \oplus H^2(M) \oplus H^4(M) \oplus H^6(M). \tag{23}$$

The central charge associated to the state η is

$$Z(t) = \int_M \frac{t^3}{6}Q^0 - \frac{t^2}{2}Q^2 + tQ^4 - Q^6. \tag{24}$$

Equating (22) and (24) we obtain relations between the topological invariant of the K-theory class η and low energy charges of a D-brane $\boldsymbol{n} = (n_6, n_4^1, n_4^2, n_0, n_2^1, n_2^2)$ in the large radius limit.

5 Examples

For example, in type IIB superstring theory we consider the topological invariants of D6-branes wrapped on $P^4_{(1,1,1,6,9)}[18]$.

In this case $\mathcal{E}$ is the vector bundle (the coherent sheaf) on the manifold M. The standard formulae

$$\mathrm{ch}\,(\mathcal{E}) = r + c_1 + \frac{1}{2}\left(c_1^2 - 2c_2\right) + \frac{1}{6}\left(c_1^2 - 3c_1c_2 + c_3\right) + \cdots,$$
$$\mathrm{Td}\,(\mathcal{E}) = 1 + \frac{1}{2}c_1 + \frac{1}{24}c_1c_2 + \cdots.$$

give possibility to rewrite the charge (23) in the form

$$Q = \left(r, c_1(\mathcal{E}), \mathrm{ch}_2(\mathcal{E}) + \frac{r}{24}c_2(M), \mathrm{ch}_3(\mathcal{E}) + \frac{1}{24}c_1(\mathcal{E})c_2(M)\right). \tag{25}$$

At the large radius limit we have following expression for these periods of holomorphic three form $\hat{\Omega}$ of the mirror manifolds W.

$$\begin{pmatrix} \Pi_1 \\ \Pi_2 \\ \Pi_3 \\ \Pi_4 \\ \Pi_5 \\ \Pi_6 \end{pmatrix} = \begin{pmatrix} \frac{1}{2}(3t_1^3 + 3t_1^2t_2 + t_1t_2^2) + \frac{17}{4}t_1 + \frac{3}{2}t_2, \\ -\frac{1}{2}t_2^2 + \frac{3}{2}t_1 + \frac{3}{2}, \\ -\frac{1}{2}(3t_1^2 + 2t_1t_2) + \frac{3}{2}t_1 + \frac{3}{2}, \\ 1 \\ t_1 \\ t_2 \end{pmatrix}, \tag{26}$$

for $P^4_{(1,1,2,6,9)}[18]$ surface,

$$\begin{pmatrix} \Pi_1 \\ \Pi_2 \\ \Pi_3 \\ \Pi_4 \\ \Pi_5 \\ \Pi_6 \end{pmatrix} = \begin{pmatrix} \frac{2}{3}t_1^3 + t_1^2t_2 + \frac{13}{6}t_1 + t_2 \\ \frac{1}{6} - 2t_1t_2 \\ 1 - t_1^2 \\ 1 \\ t_1 \\ t_2 \end{pmatrix}, \quad \begin{pmatrix} \Pi_1 \\ \Pi_2 \\ \Pi_3 \\ \Pi_4 \\ \Pi_5 \\ \Pi_6 \end{pmatrix} = \begin{pmatrix} \frac{4}{3}(3t_1^3 + 2t_1t_2 + \frac{7}{3}t_1 + t_2 \\ -4t_1t_2 + 4t_1 - 2t_2 + \frac{1}{3} \\ -2t_1^2 - 2t_1 + 1 \\ 1 \\ t_1 \\ t_2 \end{pmatrix}. \tag{27}$$

for $P^4_{(1,1,2,2,2)}[8]$ and $P^4_{(1,1,2,2,6)}[12]$ surfaces, respectively. Using formulae (22), (23), (24), (26), (27) we obtain the topological invariants of D6-branes

$$\begin{aligned}
&r = n_6,\\
&\mathrm{ch}_1(\mathcal{E}) = n_4^1 E + n_4^2 L,\\
&\mathrm{ch}_2(\mathcal{E}) = \left(\frac{3}{2}n_4^2 + n_2^1\right) h + \left(\frac{3}{2}n_4^1 + n_2^2\right) l\\
&\mathrm{ch}_3(\mathcal{E}) = -n_0 + \frac{1}{2}n_4^1 - 3n_4^2,
\end{aligned} \tag{28}$$

wrapped on $P^4_{(1,1,1,6,9)}[18]$ surface,

$$\begin{aligned}
&r = n_6,\\
&\mathrm{ch}_1(\mathcal{E}) = n_4^1 E + n_4^2 L,\\
&\mathrm{ch}_2(\mathcal{E}) = (4n_4^1 - 2n_4^2 + n_2^1)h + (-2n_4^1 + n_2^2)l,\\
&\mathrm{ch}_2(\mathcal{E}) = -n_0 - \frac{2}{3}n_4^1 - 2n_4^2,
\end{aligned} \tag{29}$$

wrapped on $P^4_{(1,1,2,2,2)}[8]$,

$$\begin{aligned}
&r = n_6,\\
&\mathrm{ch}_1(\mathcal{E}) = n_4^1 E + n_4^2 L,\\
&\mathrm{ch}_2(\mathcal{E}) = 4n_2^1 h + n_2^2 l,\\
&\mathrm{ch}_2(\mathcal{E}) = -n_0 - \frac{1}{3}n_4^1 - 2n_4^2,
\end{aligned} \tag{30}$$

wrapped on $P^4_{(1,1,2,2,6)}[12]$.

6 Localized D-branes on hypersurfaces

Let $i : D \hookrightarrow M$ be embedding of an even projective surface D in a Calabi–Yau manifold M. We can obtain class of D-brane states by wrapping D-branes on submanifold D. Multiple brane configurations are described by coherent sheaf $\mathcal{E}$ on D. The charge of this configuration is defined by torsion coherent sheaf $i_*\mathcal{E}$ which is the extension $\mathcal{E}$ by zero to the manifold M. The Grothendieck–Riemann–Roch formula for the embedding $i : D \hookrightarrow M$ gives Mukai vector

$$i_*(\mathrm{ch}\,(\mathcal{E})\,\mathrm{Td}\,(D)) = \mathrm{ch}\,(i_*\mathcal{E})\,\mathrm{Td}\,(M).$$

From this formula and from the topological invariants of the sheaf $\mathcal{E}$ on D we obtain topological invariants of the torsion sheaf $i_*\mathcal{E}$

$$\begin{aligned}
&\mathrm{ch}_1(i_*\mathcal{E}) = rD,\\
&\mathrm{ch}_2(i_*\mathcal{E}) = i_*c_1(\mathcal{E}) + \frac{r}{2}i_*c_1(\mathcal{E}),\\
&\mathrm{ch}_2(i_*\mathcal{E}) = i_*\left(\mathrm{ch}_2(\mathcal{E}) + \frac{1}{2}c_1(\mathcal{E})c_1(D) + \frac{1}{12}(c_1(D))^2 + c_2(D)\right) - \frac{r}{12}Dc_2(M).
\end{aligned} \tag{31}$$

and Mukai charge vector

$$\begin{aligned}
Q = \Big(&0, rD, i_*c_1(\mathcal{E}) + \frac{r}{2}i_*c_1(D),\\
&\mathrm{ch}_2(\mathcal{E}) + \frac{1}{2}c_1(\mathcal{E})c_1(D) + \frac{r}{12}\big(c_1(D) + c_2(D)\big) - \frac{r}{24}Dc_2(D)\Big).
\end{aligned} \tag{32}$$

By means of an adjunction formula

$$Dc_2(M) = c_2(D) - D^2 = c_2(D) - D^3 = c_2(D) - c_1(D)^2$$

this Mukai charge vector can be represented as

$$Q = \left(0, rD, i_*c_1(\mathcal{E}) + \frac{r}{2}i_*c_1(D), \mathrm{ch}_2(\mathcal{E}) + \frac{1}{2}c_1(\mathcal{E})c_1(D) + \frac{r}{8}c_1(D)^2 + \frac{r}{24}Dc_2(D)\right) \tag{33}$$

and central charge associated to it can be rewritten

$$\begin{aligned} Z(Q) = &-\frac{r}{2}t^2D + \left(i_*c_1(\mathcal{E}) + \frac{r}{2}i_*c_1(D)\right)t - \mathrm{ch}_2(\mathcal{E}) \\ &- \frac{1}{2}c_1(\mathcal{E})c_1(D) - \frac{r}{8}c_1(D)^2 - \frac{r}{24}c_1(D). \end{aligned} \tag{34}$$

In type IIB superstring theory the topological invariants D-4 branes wrapped on some hypersurfaces of the Calabi–Yau manifold can be defined. It is easy to obtain topological invariants of the D4-branes wrapped on the exceptional divisor E corresponding to BPS state with the charge vector $\boldsymbol{n} = (0, n_4^1, 0, n_0, 0, n_2^2)$ and with the central charge $Z(\boldsymbol{n}) = n_4^1\mathcal{F}^1 + n_2^2t^2 + n_0$ for the $P^4_{(1,1,2,6,9)}$ model

$$\begin{aligned} &r = n_4^1, \\ &c_1(\mathcal{E}) = n_l^2, \\ &c_2(\mathcal{E}) = \frac{1}{2}n_2^2(n_2^2+3) + n_4^1 + n_0), \end{aligned} \tag{35}$$

and with the charge $\boldsymbol{n} = (0, n_4^1, 0, n_0, n_2^1, n_2^2)$ and the central charges $Z(\boldsymbol{n}) = n_4^1\mathcal{F}^1 + n_2^1t^1 + n_2^2t_2 + n_0$ for the $P^4_{(1,1,2,2,2)}[8]$ and $P^4_{(1,1,2,2,6)}[12]$ models

$$\begin{aligned} &r(\mathcal{E}) = n_4^1, \\ &c_1(\mathcal{E}) = (n_2^1 + \nu n_4^1)h + \left(n_2^2 - \frac{\nu}{2}n_4^1\right)l, \\ &\mathrm{ch}(\mathcal{E}) = -\frac{3}{2}\nu n_4^1 - \frac{1}{2}n_2^1 + n_2^2 - n_0. \end{aligned} \tag{36}$$

where $\nu = -2, -4$. The same method may be used to define the topological invariants of D-branes on the surface (17). This surface is an elliptic fibration over a Hirzebruch surface which itself is a P^1-fibration over P^1. As in the cases considered above this fibration structure is essentially for investigation of the monodromy around singular points in the moduli space.

7 Monodromy

Consider complex function $f(z) = \sqrt{z}$. If we circle once the origin $z \to z\exp 2i\pi$, then $f(z\exp 2i\pi) = -f(z)$. The function does not return back to itself. This is signal that the function at the point $z = 0$ is singular and in this case it is the start of a branch cut.

The behavior of a complex function or set of functions after transport around a singular point (singularity) is connected with their monodromy. In general, a set of function transported once around the singular point t_0 return to the linear combination of themselves $f_i((z-z_0)\exp 2i\pi) = m_{ij}(z_0)f_j(z)$. The matrix m_{ij} depend on the singular point and it is called by the monodromy matrix. It does not change under smooth deformations of the contour. The monodromy has topological characteristic.

In general, one of the important problems of algebraic geometry is to study families of algebraic variety parameterized by another variety. A subvariety in moduli space parameterizing the singular fibers has the special interest. This subvariety is called the discriminant locus. One of the main its topological invariants is so-called monodromy group. It is defined by the action of homotopy group of the complement of discriminant locus on cohomology ring of fixed nonsingular fiber. The large radius limit point is situated in the intersection of the two divisors H and L on the boundary of the moduli space [6]. The monodromy matrices of the two divisors E, H, are expressed with respect to the (E, L) basis [5, 6] by

$$S_L = \begin{pmatrix} 1 & -1 & -3 & 10 & 9 & 3 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & -3 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \qquad S_H = \begin{pmatrix} 1 & 0 & -1 & 3 & 2 & 0 \\ 0 & 1 & 0 & 1 & 0 & -1 \\ 0 & 0 & 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \tag{37}$$

for $P^4_{(1,1,1,6,9)}[18]$ model,

$$S_L = \begin{pmatrix} 1 & 0 & -1 & 2 & -2 & 0 \\ 0 & 1 & 0 & -2 & -4 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \qquad S_H = \begin{pmatrix} 1 & -1 & -2 & 6 & 4 & 0 \\ 0 & 1 & 0 & 4 & 0 & -4 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 \end{pmatrix} \tag{38}$$

for $P^4_{(1,1,2,2,2)}[8]$ model,

$$S_L = \begin{pmatrix} 1 & 0 & -1 & 20 & 0 & 0 \\ 0 & 1 & 0 & 0 & -2 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix}, \qquad S_H = \begin{pmatrix} 1 & -1 & -2 & 5 & 2 & 1 \\ 0 & 1 & 0 & 0 & 0 & -2 \\ 0 & 0 & 1 & -1 & -2 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \tag{39}$$

for $P^4_{(1,1,2,2,6)}[12]$ model. We can use above formulae to convert the monodromy transformations (37), (38), (39) into automorphisms of K-group $K(M)$

$$[\mathcal{E}] \to [\mathcal{E} \otimes \mathcal{O}_M(L)], [\mathcal{E}] \to [\mathcal{E} \otimes \mathcal{O}_M(H)], \tag{40}$$

where $[\mathcal{E}] \in K(M)$. The topological invariants of the sheaf $\mathcal{E}' = \mathcal{E} \otimes \mathcal{O}_M(D)$ under the transformation (40) change to the form

$$\begin{aligned} &r(\mathcal{E}') = r(\mathcal{E}), \\ &\mathrm{ch}_1(\mathcal{E}') = \mathrm{ch}_1(\mathcal{E}) + rD, \\ &\mathrm{ch}_2(\mathcal{E}') = \mathrm{ch}_2(\mathcal{E}) + \mathrm{ch}_1(\mathcal{E})D + \frac{r}{2}D^2, \\ &\mathrm{ch}_3(\mathcal{E}') = \mathrm{ch}_3(\mathcal{E}) + \mathrm{ch}_2(\mathcal{E})D + \frac{1}{2}\mathrm{ch}_1(\mathcal{E})D^2 + \frac{r}{6}D^3, \end{aligned} \tag{41}$$

where $D = H$, L. The representations of these transformations on the space of charge vectors $\boldsymbol{n} = (n_0, n_4^1, n_4^2, n_0, n_2^1, n_2^2)$ and transformations (37), (38), (39) are connected by the relation

$$M(D) = S_D^{-1}. \tag{42}$$

8 Conclusions

In this paper, we have considered the method of the D-brane constructions in superstring theory corresponding to Calabi–Yau compactification where Calabi–Yau manifolds appear as hypersurfaces in the weighted projective space. In the large volume "phase" of the Kähler moduli space this construction provides clear geometric picture of the D-brane spectrum. We find that this construction gives clear picture of the large volume monodromy transformations. All the above is a simple particular case of a more ambitious program which proposes for type IIB superstring theory an identification of the D-branes by objects of a derived category of the category of coherent sheaves [7, 8] (see also [9]).

We show the results for the DGLAP and BFKL evolution equations in the $N = 4$ supersymmetric gauge theory obtained earlier in the next-to-leading approximation. The eigenvalue of the BFKL kernel in this model turns out to be an analytic function of the conformal spin $|n|$. The corresponding kernel for the Bethe–Salpeter equation has the property of the Hermitian separability. The anomalous dimension matrix can be transformed to a triangle form with the use of the similarity transformation for the diagonalization of the anomalous dimension matrix in the leading order. The eigenvalues of these matrices can be expressed in terms of a universal function by an integer shift of its argument. We also investigate in this approximation possible relations between the DGLAP and BFKL equations.

1 Introduction

The Balitsky–Fadin–Kuraev–Lipatov (BFKL) equation [1] and the Dokshitzer–Gribov–Lipatov–Altarelli–Parisi (DGLAP) equation [2] are used now for a theoretical description of structure functions of the deep-inelastic ep scattering at small values of the Bjorken variable x. The higher-order QCD corrections to the splitting kernels of the DGLAP equation are well known. But the calculation of the next-to-leading order (NLO) corrections to the BFKL kernel was completed recently [3, 4].

In supersymmetric gauge theories the structure of the BFKL and DGLAP equations is simplified significantly. In the case of an extended $N = 4$ SUSY the NLO corrections to the BFKL equation were calculated in ref. [4] for arbitrary values of the conformal spin n. Below these results are presented in the dimensional reduction ($\overline{\rm DR}$) scheme [5] which does not violate the supersymmetry. The analyticity of the eigenvalue of the BFKL kernel as a function of the conformal spin $|n|$ gives a possibility to relate in the leading logarithmic approximation (LLA) the DGLAP and BFKL equations in this model (see [4]). It was shown [6] that the eigenvalue of the BFKL kernel has the property of Hermitian separability similar to the holomorphic separability.

Let us introduce the unintegrated parton distributions $\varphi_a(x, k_\perp^2)$ (hereafter $a = q, g, \varphi$ for the spinor, vector and scalar particles, respectively) and the (integrated) parton distributions $n_a(x, Q^2)$. In DIS $Q^2 = -q^2$ and $x = Q^2/(2pq)$ are the Bjorken variables, $k_\perp$ is the transverse component of the parton momentum and q and p are the photon and hadron momenta, respectively.

After the Mellin transformation of partonic distributions $n_a\big(x, Q^2\big)$ the DGLAP equation can be written as follows [2]

$$\frac{d}{d\ln Q^2}\, n_a\big(j, Q^2\big) = \sum_b \gamma_{ab}(j)\, n_b\big(j, Q^2\big) \qquad \left(n_a\big(j, Q^2\big) = \int_0^1 dx\, x^{j-1} n_a\big(x, Q^2\big)\right).$$

The Mellin moment of the splitting kernel $\gamma_{ab}(j)$ coincides with the anomalous dimension

(AD) matrix for the twist-2 operators[1]. These operators are constructed as bilinear combinations of the fields which describe corresponding partons

$$
\begin{aligned}
&O^g_{\mu_1,\ldots,\mu_j} = \hat{S} G_{\rho\mu_1} D_{\mu_2} D_{\mu_3} \cdots D_{\mu_{j-1}} G_{\rho\mu_j}, \qquad && \tilde{O}^g_{\mu_1,\ldots,\mu_j} = \hat{S} G_{\rho\mu_1} D_{\mu_2} D_{\mu_3} \cdots D_{\mu_{j-1}} \tilde{G}_{\rho\mu_j},\\
&O^q_{\mu_1,\ldots,\mu_j} = \hat{S} \overline{\Psi} \gamma_{\mu_1} D_{\mu_2} \cdots D_{\mu_j} \Psi, && \tilde{O}^q_{\mu_1,\ldots,\mu_j} = \hat{S} \overline{\Psi} \gamma_5 \gamma_{\mu_1} D_{\mu_2} \cdots D_{\mu_j} \Psi,\\
&O^\varphi_{\mu_1,\ldots,\mu_j} = \hat{S} \bar{\Phi} D_{\mu_1} D_{\mu_2} \cdots D_{\mu_j} \Phi, && \qquad (1)
\end{aligned}
$$

where the spinor Ψ and field tensor $G_{\rho\mu}$ describe gluinos and gluons, respectively. The last expression is constructed from the covariant derivatives D_μ of the scalar field Φ appearing in extended supersymmetric models. The symbol $\hat{S}$ implies a symmetrization of the tensor in the Lorenz indices $\mu_1, \ldots, \mu_j$ and a subtraction of its traces.

On the other hand, the BFKL equation relates the unintegrated gluon distributions with small values of the Bjorken variable x:

$$
\frac{d}{d\ln(1/x)} \varphi_g(x, k_\perp^2) = 2\omega(-k_\perp^2) \varphi_g(x, k_\perp^2) + \int d^2 k'_\perp K(k_\perp, k'_\perp) \varphi_g\big(x, (k'_\perp)^2\big),
$$

where $\omega(-k_\perp^2) < 0$ is the gluon Regge trajectory [1].

The matrix elements of $O^a_{\mu_1,\ldots,\mu_j}$ and $\tilde{O}^a_{\mu_1,\ldots,\mu_j}$ are related to the moments of the parton distributions $n_a\big(x, Q^2\big)$ and $\Delta n_a\big(x, Q^2\big)$ in a hadron h in the following way

$$
\begin{aligned}
&\int_0^1 dx\, x^{j-1} n_a\big(x, Q^2\big) = \langle h \,|\, \tilde{n}^{\mu_1} \cdots \tilde{n}^{\mu_j} O^a_{\mu_1,\ldots,\mu_j} \,|\, h \rangle, \qquad a = (q, g, \varphi),\\
&\int_0^1 dx\, x^{j-1} \Delta n_a\big(x, Q^2\big) = \langle h \,|\, \tilde{n}^{\mu_1} \cdots \tilde{n}^{\mu_j} \tilde{O}^a_{\mu_1,\ldots,\mu_j} \,|\, h \rangle, \qquad a = (q, g). \qquad (2)
\end{aligned}
$$

Here the vector $\tilde{n}^\mu$ is light-like: $\tilde{n}^2 = 0$. Note, that in the deep-inelastic ep scattering we have $\tilde{n}^\mu \sim q^\mu + x p^\mu$.

The quantum numbers appeared in the solution of the BFKL equation being the integer conformal spin $|n|$ and the quantity $1 + \omega$ (ω is an eigenvalue of the BFKL kernel) coincides respectively with the total numbers of transversal and longitudinal Lorentz indices of the tensor $O^a_{\mu_1,\ldots,\mu_J}$ with the rank $J = 1 + \omega + |n|$. The corresponding matrix elements can be expressed through the solution of the BFKL equation

$$
\tilde{n}^{\mu_1} \cdots \tilde{n}^{\mu_{1+\omega}} l_\perp^{\mu_{2+\omega}} \cdots l_\perp^{\mu_j} \langle P \,|\, O^g_{\mu_1,\ldots,\mu_j} \,|\, P \rangle \sim \int_0^1 dx x^\omega \int d^2 k_\perp \left(\frac{k_\perp}{|k_\perp|} \right)^n \varphi_g\big(x, k_\perp^2\big).
$$

It is important that the AD matrices $\gamma_{ab}(j)$ and $\tilde{\gamma}_{ab}(j)$ for the twist-2 operators $O^a_{\mu_1,\ldots,\mu_j}$ and $\tilde{O}^a_{\mu_1,\ldots,\mu_j}$ do not depend on various projections of indices due to the Lorentz invariance. But generally the Lorentz spin j is less then J. Thus, it looks reasonable to extract some additional information concerning the parton x-distributions satisfying the DGLAP equation from the analogous $k_\perp$-distributions satisfying the BFKL equation.

In LLA the integral kernel of the BFKL equation is the same in all supersymmetric gauge theories. Due to the Möbius invariance in the impact parameter representation the solution of the homogeneous BFKL equation has the form (see [7])

$$
E_{\nu,n}(\overrightarrow{\rho_{10}}, \overrightarrow{\rho_{20}}) \equiv \langle \phi(\overrightarrow{\rho_1}) O_{m,\tilde{m}}(\overrightarrow{\rho_0})\, \phi(\overrightarrow{\rho_2}) \rangle = \left(\frac{\rho_{12}}{\rho_{10}\rho_{20}} \right)^m \left(\frac{\rho^*_{12}}{\rho^*_{10}\rho^*_{20}} \right)^{\widetilde{m}},
$$

[1] As in ref. [3,4], the anomalous dimensions differ from those used usually in the description of DIS by a factor (-2), i.e. $\gamma_{ab}(j) = (-1/2)\gamma^{\rm DIS}_{ab}(j)$.

where $m = 1/2 + i\nu + n/2$ and $\widetilde{m} = 1/2 + i\nu - n/2$ are conformal weights related to the eigenvalues of the Casimir operators of the Möbius group. We introduced also the complex variables $\rho_k = x_k + iy_k$ in the transverse subspace and used the notation $\rho_{kl} = \rho_k - \rho_l$.

For the principal series of the unitary representations the quantities ν and n are respectively real and integer numbers. The projection n of the conformal spin $|n|$ can be positive or negative, but the eigenvalue of the BFKL equation in LLA [1]

$$\omega = \omega^0(n,\nu) = 8\overline{a}\left(\Psi(1) - \mathrm{Re}\,\Psi\left(\frac{1}{2} + i\nu + \frac{|n|}{2}\right)\right), \qquad \overline{a} = \frac{g^2 N_c}{16\pi^2} = \frac{\alpha_s N_c}{4\pi} \tag{3}$$

depends only on $|n|$. The Möbius invariance takes place also for the Schrödinger equation describing the composite states of several reggeized gluons [8]. As a consequence of the relation

$$\omega^0(n,\nu) = \omega^0(m) + \omega^0(\widetilde{m}), \qquad \omega^0(m) = 2\overline{a}\big(2\Psi(1) - \Psi(m) - \Psi(1-m)\big).$$

one obtains the property of the holomorphic separability $H = h + h^*$, $[h, h^*] = 0$ for the Hamiltonian of an arbitrary number of reggeized gluons in the multi-colour QCD [9]. In the same limit the BFKL dynamics is completely integrable [10, 11] and the holomorphic Hamiltonian h coincides with the local Hamiltonian for an integrable Heisenberg spin model [12]. Moreover the theory turns out to be invariant under the duality transformation [13]. Presumably the remarkable mathematical properties of the reggeon dynamics in LLA are consequences of the extended $N = 4$ supersymmetry [14]. It was argued also in ref. [14] that generalized DGLAP equations for the matrix elements of quasi-partonic operators [15] for $N = 4$ SUSY are integrable.

The solution of the inhomogeneous BFKL equation in the LLA approximation can be constructed in the impact parameter representation and for $\overrightarrow{\rho_{1'}} \to \overrightarrow{\rho_{2'}}$ we obtain [7]

$$\langle \phi(\overrightarrow{\rho_1})\,\phi(\overrightarrow{\rho_2})\,\phi(\overrightarrow{\rho_{1'}})\,\phi(\overrightarrow{\rho_{2'}})\rangle \sim \sum_n C(\nu_\omega, |n|)\frac{E_{\nu_\omega,|n|}(\overrightarrow{\rho_{11'}}, \overrightarrow{\rho_{21'}})}{\omega'(|n|,\nu_\omega)}|\rho_{1'2'}|^{1+2i\nu_\omega}\left(\frac{\rho_{1'2'}}{\rho^*_{1'2'}}\right)^{|n|/2},$$

where ν_ω is a solution of the equation $\omega = \omega^0(|n|,\nu)$ with $\mathrm{Im}\,\nu_\omega < 0$.

The above asymptotics has a simple interpretation in terms of the Wilson operator-product expansion of two reggeon fields produced the local operator $O_{\nu_\omega,|n|}(\overrightarrow{\rho_{1'}})$ having the transverse dimension $\Gamma_\omega = 1 + i\nu_\omega$ calculated in units of a squared mass. The corresponding tensor has a mixed projections of a gauge-invariant tensor O with $J = 1 + \omega + |n|$ indices. Note, that because Γ_ω is real in the deep-inelastic regime $\rho_{12} \to 0$, the operator $O_{\nu_\omega,|n|}(\overrightarrow{\rho_{1'}})$ belongs to an exceptional series of unitary representations of the Möbius group (see [16]).

The AD $\gamma(j)$ obtained from the BFKL equation in LLA (3) has the poles

$$\Gamma_\omega = 1 + \frac{|n|}{2} - \gamma(j), \qquad \gamma(j)|_{\omega\to 0} = \frac{4\overline{a}}{\omega}. \tag{4}$$

The operator $O_{\nu_\omega,|n|}$ for $|n| = 1, 2, \ldots$ has the twist higher than 2 because its AD γ is singular at $\omega \to 0$. In the paper [4] the analytic continuation of the BFKL AD $\gamma(|n|,\omega)$ to the points $|n| = -r - 1$ $(r = 0, 1, 2, \ldots)$ was suggested to calculate the AD singularities in the twist-2 operators in negative integer $J = 1 + \omega + |n| \to -r$. Because for positive $|n|$ and $\omega \to 0$ the quantity $\gamma(|n|,\omega)$ corresponds to higher twist operators, to obtain γ for the twist-2 operators, one should push $\Delta|n| = |n| + r + 1$ to zero at $\omega \to 0$ sufficiently rapidly $\Delta|n| = C(r)\omega^2$. In LLA the results obtained from the BFKL equation $\gamma(j)|_{j\to -r} = \frac{4\overline{a}}{j+r}$ for $r = -1, 0, 1, \ldots$ coincide with the direct calculation of the eigenvalues of the AD matrix $\gamma_{a,b}$ for $N = 4$ SUSY in accordance with the fact, that only in this theory the eigenvalue of the BFKL equation is an analytic function of $|n|$ [4]. It is important that the AD is the same for all twist-2 operators entering in the $N = 4$ supermultiplet up to a shift of its argument by an integer number, because this

property leads to an integrability of the evolution equations for quasi-partonic operators [15] in the multi-color limit $N_c \to \infty$ (see [14]).

In the NLO approximation for the BFKL equation there is a difficulty related to an appearance of the double-logarithmic (DL) terms leading to triple poles at $j = -r$ for even r. The origin of the DL terms can be understood in a simple way using as an example the process of the forward annihilation of the e^+e^- pair in the $\mu^+\mu^-$ pair in QED [17]. For this process the t-channel partial wave f_ω ($\omega = j$) in the DL approximation can be written as follows $f_\omega = \frac{\gamma^{-1}}{\omega} - \frac{\alpha_{em}}{2\pi\left(\frac{1}{\omega-\gamma}+\frac{1}{\gamma}\right)}$. By expanding perturbatively the position of the pole in γ we shall generate the triple pole term in the AD $\Delta\gamma \sim \alpha_{em}^2/\omega^3$.

It is important to note that the equation for the pole position of f_ω is similar to the BFKL equation in the modified leading logarithmic approximation

$$\omega \sim 2\Psi(1) - \Psi(1 + |n| + \omega - \gamma) - \Psi(\gamma), \qquad |n| = -1, -2, \dots .$$

2 NLO corrections to the BFKL kernel in the $N = 4$ SUSY

Let us introduce the new variables $M = \gamma + \frac{|n|}{2}$, $\widetilde{M} = \gamma - \frac{|n|}{2}$, $\gamma = \frac{1}{2} + i\nu$. Then the eigenvalue relation for the BFKL equation in the $\overline{\rm DR}$-scheme can be written in the Hermitially separabel form [6]

$$1 = \frac{4\widehat{a}}{\omega}\left(2\Psi(1) - \Psi(M) - \Psi(1-\widetilde{M}) + \widehat{a}\left(\phi(M) + \phi(1-\widetilde{M})\right)\right) - 2\widehat{a}\left(\rho(M) + \rho(1-\widetilde{M})\right), \qquad \widehat{a} = \overline{a} + \frac{\overline{a}^2}{3}, \qquad \overline{a} = \frac{g^2 N_c}{16\pi^2}, \tag{5}$$

where $\overline{a}$ (see (3)) and $\widehat{a}$ are expressed through the Yang–Mills constants g in the $\overline{\rm MS}$ and $\overline{\rm DR}$-schemes, respectively, and

$$\rho(M) = \beta'(M) + \frac{1}{2}\zeta(2), \quad \phi(M) = 3\zeta(3) + \Psi''(M) - 2\Phi_2(M) + 2\beta'(M)\big(\Psi(1) - \Psi(M)\big). \tag{6}$$

Here

$$\Psi(M) = \frac{\Gamma'(M)}{\Gamma(M)}, \quad \beta'(z) = \sum_{l=0}^{\infty}\frac{(-1)^{l+1}}{(l+z)^2}, \quad \Phi_2(M) = \sum_{k=0}^{\infty}\frac{\big(\beta'(k+1) + (-1)^k\Psi'(k+1)\big)}{k+M}.$$

In the right-hand side of the eigenvalue equation the first contribution corresponds to the singularity at $l = -1$ generated by the pole of the Legendre function $Q_l(x)$ in the kernel at $\omega = 1 + l \to 0$ and the last term appears from the regular part of the Born contribution. Note that M and $1 - \widetilde{M}$ coincide with the anomalous dimensions appearing in the asymptotical expressions for the BFKL kernel in the limits when the gluon virtualities are large: $q_1^2 \to \infty$ and $q_2^2 \to \infty$, respectively. Because $1 - \widetilde{M} = M^*$, the Hermitian separability guarantees the symmetry of ω for the principal series of the unitary representations of the Möbius group to the substitution $\nu \to -\nu$ and the Hermicity of the BFKL Hamiltonian. It turns out, however, that the holomorphic separability corresponding to the symmetry $m \leftrightarrow \tilde{m}$ is violated in the NLO approximation [6].

Analogously to refs. [3, 4] one can calculate the eigenvalues of the BFKL kernel in the case of the non-symmetric choice for the energy normalization s_0 in equation (15) related to the interpretation of the NLO corrections in the framework of the renormalization group. For the scale $s_0 = q^2$ natural for the deep-inelastic scattering we obtain the corresponding eigenvalue equation

$$1 = 4\hat{a}\omega^{-1}\left(2\Psi(1) - \Psi(\gamma) - \Psi(J-\gamma) + \hat{a}\left(\phi(\gamma) + \phi(J-\gamma)\right)\right) + 2\hat{a}\left(\Psi'(\gamma) - \rho(\gamma) + \Psi'(J-\gamma) - \rho(J-\gamma)\right). \tag{7}$$

3 Anomalous dimension matrix in the $N = 4$ SUSY

In LLA AD matrices in the N=4 SUSY have the following form (see [18]):
for tensor twist-2 operators (hereafter $\Psi(j+1) - \Psi(1) \equiv S_1(j)$)

$$\gamma_{gg}^{(0)}(j) = 4\left(-S_1(j-2) - \frac{2}{j} + \frac{1}{j+1} - \frac{1}{j+2}\right), \qquad \gamma_{qg}^{(0)}(j) = 8\left(\frac{1}{j} - \frac{2}{j+1} + \frac{2}{j+2}\right),$$
$$\gamma_{\varphi g}^{(0)}(j) = 12\left(\frac{1}{j+1} - \frac{1}{j+2}\right), \qquad \gamma_{gq}^{(0)}(j) = 2\left(\frac{2}{j-1} - \frac{2}{j} + \frac{1}{j+1}\right), \qquad \gamma_{q\varphi}^{(0)}(j) = \frac{8}{j},$$
$$\gamma_{qq}^{(0)}(j) = 4\left(-S_1(j-1) + \frac{1}{j} - \frac{2}{j+1}\right), \qquad \gamma_{\varphi q}^{(0)}(j) = \frac{6}{j+1},$$
$$\gamma_{\varphi\varphi}^{(0)}(j) = -4S_1(j), \qquad \gamma_{g\varphi}^{(0)}(j) = 4\left(\frac{1}{j-1} - \frac{1}{j}\right), \tag{8}$$

for the pseudo-tensor operators:

$$\tilde\gamma_{gg}^{(0)}(j) = 4\left(-S_1(j) - \frac{2}{j+1} + \frac{2}{j}\right), \qquad \tilde\gamma_{qq}^{(0)}(j) = 4\left(-S_1(j) + \frac{1}{j+1} - \frac{1}{j}\right),$$
$$\tilde\gamma_{qg}^{(0)}(j) = 8\left(-\frac{1}{j} + \frac{2}{j+1}\right), \qquad \tilde\gamma_{gq}^{(0)}(j) = 2\left(\frac{2}{j} - \frac{1}{j+1}\right). \tag{9}$$

Note that in the $N = 4$ SUSY multiplet there are twist-2 operators with fermion quantum numbers but their AD are the same as for the bosonic components of the corresponding supermultiplet (cf. ref. [15]). It is possible to construct 5 independent twist-two operators with a multiplicative renormalization. The corresponding parton distribution momenta and their LLA AD have the form [18]:

$$n_I(j) = n_g^j + n_q^j + n_\varphi^j, \qquad \gamma_I^{(0)}(j) = -4S_1(j-2) \equiv \gamma_+^{(0)}(j),$$
$$n_{II}(j) = -2(j-1)n_g^j + n_q^j + \frac{2}{3}(j+1)n_\varphi^j, \qquad \gamma_{II}^{(0)}(j) = -4S_1(j) \equiv \gamma_0^{(0)}(j),$$
$$n_{III}(j) = -\frac{j-1}{j+2}n_g^j + n_q^j - \frac{j+1}{j}n_\varphi^j, \qquad \gamma_{III}^{(0)}(j) = -4S_1(j+2) \equiv \gamma_-^{(0)}(j),$$
$$n_{IV}(j) = 2\Delta n_g^j + \Delta n_q^j, \qquad \gamma_{IV}^{(0)}(j) = -4S_1(j-1) \equiv \tilde\gamma_+^{(0)}(j),$$
$$n_V(j) = -(j-1)\Delta n_g^j + \frac{j+2}{2}\Delta n_q^j, \qquad \gamma_V^{(0)}(j) = -4S_1(j+1) \equiv \tilde\gamma_-^{(0)}(j).$$

Thus, we have one supermultiplet of operators with the same AD $\gamma^{\rm LLA}(j)$ proportional to $\Psi(1) - \Psi(j-1)$. The momenta of the corresponding linear combinations of the parton distributions can be obtained from the above expressions by an appropriate shift of their argument j to obtain this universal anomalous dimension $\gamma^{\rm LLA}(j)$. Moreover, the coefficients in these linear combinations for $N = 4$ SUSY can be found from the super-conformal invariance (cf. ref. [15]). However, in two-loop approximation these coefficients are slightly renormalized [19] due to the breaking of the conformal invariance [20]. In the paper [6] using some plausible arguments an universal AD in two-loops for $N = 4$ SUSY in the $\overline{\rm DR}$-scheme was suggested. Other AD are obtained by an integer shift of its arguments. These results were justified by a direct calculation of the AD matrix in ref. [19][2]. With the use of the basis for the multiplicatively renormalizable operators obtained in LLA in [6] one can transform this matrix to a triangle form. The diagonal elements of the triangle matrix are expressed in terms of the universal AD $\gamma(j)$ by an appropriate integer shift of its argument:

$$\gamma(j) = -4\hat a\big(S_1(j-2) + 4\hat a Q(j-2)\big), \tag{10}$$

[2]Note that in [19] the results have been obtained in $\overline{\rm DR}$-scheme but with the $\overline{\rm MS}$ coupling constant $\overline{a}$ that leads to the additional term $-1/3S_1(j)$ in the NLO correction $Q(j)$.

where

$$Q(j) = S_{-2,1}(j) - S_1(j)\big(S_2(j) + S_{-2}(j)\big) - \big(S_3(j) + S_{-3}(j)\big)/2,$$
$$S_k(n) = \sum_{i=1}^{n} \frac{1}{i^k}, \qquad \zeta(k) = \sum_{i=1}^{\infty} \frac{1}{i^k}, \qquad S_{-k}(n) = \sum_{i=1}^{n} \frac{(-1)^i}{i^k}, \qquad S_{-k,l}(n) = \sum_{i=1}^{n} \frac{(-1)^i}{i^k} S_l(i).$$

The analytical continuation of functions $\gamma_{ab}^{(1)}$ $(a, b = g, q, \varphi)$ and $\tilde{\gamma}_{ab}^{(1)}$ $(a, b = g, q)$ to the complex values of j can be done analogously to refs. [21, 6].

4 Relation between the DGLAP and BFKL equations

As we have discussed already above, in the case of $N = 4$ SUSY the BFKL eigenvalue is analytic in $|n|$ and one can continue the AD to the negative values of $|n|$. It gives a possibility to find the AD singular contributions in the twist-2 operators not only at $j = 1$ but also at other integer points $j = 0, -1, -2, \ldots$. As it was discussed already in the Introduction, in the Born approximation we obtain $\gamma = 4\hat{a}(\Psi(1) - \Psi(j-1))$, which coincides with the result of the direct calculations (see [14, 18]). Thus, in the case of $N = 4$ the BFKL equation presumably contains the information sufficient for restoring the kernel of the DGLAP equation. Below we investigate the relation between these equations in the NLO approximation.

Let us start with an investigation of AD singularities obtained from the DGLAP equation. By presenting the Lorentz spin j as $\omega - r$, where $r = -1, 0, 1, \ldots$ and pushing $\omega \to 0$ we can calculate the singular behavior of the universal anomalous dimension $\gamma(j)$

$$\gamma(j) = 4\hat{a}\left[\frac{1}{\omega} - S_1(r+1) + O(\omega)\right] \tag{11}$$
$$+ (4\hat{a})^2 \begin{cases} \dfrac{1}{\omega^3} - 2S_1(r+1)\dfrac{1}{\omega^2} - (\zeta(2) + S_2(r+1))\dfrac{1}{\omega} + O\big(\omega^0\big) & \text{if } r = 2m, \\ S_2(r+1)\dfrac{1}{\omega} + O\big(\omega^0\big) & \text{if } r = 2m+1. \end{cases}$$

Let us consider initially the BFKL equation in a modified LLA, i.e. when $\omega^{\rm MLLA} = 4\,\hat{a}\big(2\Psi(1) - \Psi(\gamma) - \Psi(J-\gamma)\big)$. In the limit $J = 1 + |n| + \omega \to -r + \omega$ by inverting this equation one can obtain

$$\gamma = \frac{4\hat{a}}{\omega} + (4\hat{a})^2\left[\frac{1}{\omega^3} - S_1(r)\frac{1}{\omega^2} - (\zeta(2) + S_2(r))\frac{1}{\omega}\right] + O\big(\hat{a}^3\big), \tag{12}$$

i.e. this result coincides after the shift $r \to r+1$ with the singular part of the corresponding DGLAP result for the even values of r with the exception of the coefficient in the front of $\hat{a}^2/\omega^2$.

In a general case the next-to-leading corrections contain the divergencies at $|n| \to -r - 1$. Their appearance is related to the presence of the double-logarithms. Indeed the eigenvalue relation for the Bethe–Salpeter equation can be written near $\gamma = 0$ and $J \simeq j = -r + \omega$ in the form

$$1 = \frac{4\hat{a}}{\gamma(\omega - \gamma)} + O\big(\hat{a}^2\big).$$

Because the first contribution in the right-hand side contains additional singularities in comparison with the pole $1/\omega$ in the physical case of the positive $|n|$, we should subtract from the correction $O\big(\hat{a}^2\big)$ the terms appeared in its first iteration:

$$(4\hat{a})^2 \frac{1}{\gamma^2(\omega - \gamma)^2} \simeq (4\hat{a})^2 \left(\frac{1}{\gamma^2\omega^2} + \frac{2}{\gamma\omega^3}\right).$$

This subtraction leads to the final result for even r, which is in an agreement with the fact that the double-logarithms in the universal AD $\gamma(j)$ exist at even negative j. For the odd r the divergency $\hat{a}^2/(\gamma\omega^3)$ is absent in accordance with the absence in $\gamma(j)$ of the DL terms $\sim \hat{a}^2/\omega^3$ at odd negative j. For a more accurate comparison of the singularities of the BFKL and DGLAP equations in two-loop approximation one needs to calculate in the BFKL kernel non-singular terms at $j \to -r$.

5 Conclusion

Above we reviewed the LLA and NLL results for the eigenvalue of the kernels of the BFKL and DGLAP equations in the $N = 4$ supersymmetric gauge theory and constructed the operators with a multiplicative renormalization [6]. These AD can be obtained from the universal AD $\gamma(j)$ by a shift of its argument $j \to j + k$. The NLO corrections to the AD matrix were found with the use of the plausible arguments [6] and by the direct methods [19].

Note that recently the LLA AD in this theory for large $\alpha_s N_c$ were constructed in ref. [22] in the limit $j \to \infty$ from the superstring model with the use of the Maldacena correspondence [23]. Also in $N = 4$ SUSY at large $\alpha_s N_c$ the Pomeron coincides with the graviton [24]. It will be interesting to obtain these results directly from the DGLAP and BFKL equation. Already in the perturbation theory as it was demonstrated above, the BFKL dynamics has remarkable properties: analyticity in the conformal spin $|n|$, Möbius invariance, holomorphic (and Hermitian) separability and integrability in a generalized LLA. On the other hand, for the DGLAP dynamics the AD for all twist-2 operators are proportional in LLA to the function $\Psi(1) - \Psi(j-1)$ up to an integer shift of its arguments, which corresponds to the eigenvalue of a pair Hamiltonian in the integrable Heisenberg spin model [4, 25]. The investigation of the $N = 4$ supersymmetric model should be continued in the perturbation theory and for large $\alpha_s N_c$ because it is helpful for understanding of QCD.

Three-Dimensional Integrable and Superintegrable Isospectral Potentials

Şengül KURU and Abdullah VERÇÍN

As an extension of the intertwining operator idea a constructive method for establishment of families of three-dimensional (super)integrable and isospectral potentials having higher-order dynamical symmetries is developed.

In analogy to integrability concepts of classical mechanics [1–3], a quantum mechanical system described in N dimensional (ND) Euclidean space by a stationary Hamiltonian operator H is called to be completely integrable if there exists a set of $N-1$ (together with H, N) algebraically independent linear operators commuting with H and among each other [4–8]. If there exist k ($0 < k \leq N-1$), additional operators commuting with H it is said to be superintegrable. The superintegrability is said to be minimal if $k = 1$ and maximal if $k = N-1$. Recently, the intertwining operator method has been systematically used in establishing families of $2D$ superintegrable potentials that are at the same time isospectral [9, 10]. In this letter we shall extend this program in constructing $3D$ integrable and superintegrable isospectral potentials.

The method of intertwining is a unified approach widely used in various fields of physics and mathematics [11–20]. To see the usefulness of this method let us consider two Hamiltonian operators $\mathcal{H}_0$ and $\mathcal{H}_1$ that are Hermitian (on some common function space) and intertwined by a linear intertwining operator $\mathcal{L}$ such that $\mathcal{L}\mathcal{H}_0 = \mathcal{H}_1\mathcal{L}$. Two dimension and form independent general properties [14, 15] immediately follow from such a relation; (i) If ψ^0 is an eigenfunction of $\mathcal{H}_0$ with eigenvalue of E^0 then $\psi^1 = \mathcal{L}\psi^0$ is an (unnormalized) eigenfunction of $\mathcal{H}_1$ with the same eigenvalue E^0. That is $\mathcal{L}$ transforms one solvable problem into another. (ii) $\mathcal{L}^\dagger$ intertwines in the other direction $\mathcal{H}_0\mathcal{L}^\dagger = \mathcal{L}^\dagger\mathcal{H}_1$ and this in turn provides two hidden dynamical symmetries of $\mathcal{H}_0$ and $\mathcal{H}_1$ in terms of $\mathcal{L}$: $[\mathcal{H}_0, \mathcal{L}^\dagger\mathcal{L}] = 0 = [\mathcal{H}_1, \mathcal{L}\mathcal{L}^\dagger]$, where † and $[\,,\,]$ stand for Hermitian conjugation and commutator.

In this letter we shall first apply this method to a pair of $3D$ systems described by

$$\mathcal{H}_0 = -\nabla^2 + V_0, \qquad \mathcal{H}_1 = -\nabla^2 + V_1, \tag{1}$$

and take $\mathcal{L}$ to be the following first order linear operator

$$\mathcal{L} = L_0 + \boldsymbol{L}\cdot\boldsymbol{\nabla}. \tag{2}$$

∇^2 is the Laplace operator in the Cartesian coordinates (x_1, x_2, x_3), $\boldsymbol{L} = (L_1, L_2, L_3)$ and "$\cdot$" denotes the usual inner product of $\mathbb{R}^3$. The potentials V_0, V_1 and L_0, $\boldsymbol{L}$ are some functions of coordinates that are to be determined from consistency equations of $\mathcal{L}\mathcal{H}_0 = \mathcal{H}_1\mathcal{L}$ which for (1) and (2) takes the form:

$$[\nabla^2, \boldsymbol{L}\cdot\boldsymbol{\nabla}] = -[\nabla^2, L_0] + [V_0, \boldsymbol{L}\cdot\boldsymbol{\nabla}] + \mathcal{P}\,\mathcal{L}, \tag{3}$$

where $\mathcal{P} = V_1 - V_0$.

By equating the second power of partial derivatives $\partial_j \equiv \partial/\partial x_j$ in equation (3) (these come only from $[\nabla^2, \boldsymbol{L}\cdot\boldsymbol{\nabla}]$) we obtain

$$\boldsymbol{L} = \boldsymbol{a} - \boldsymbol{b}\times\boldsymbol{r}, \tag{4}$$

where $\boldsymbol{a}=(a_1,a_2,a_3)$, $\boldsymbol{b}=(b_1,b_2,b_3)$ are arbitrary constant vectors and "$\times$" stands for the usual cross product of $\mathbb{R}^3$. In terms of vector operators $\boldsymbol{T}=\boldsymbol{\nabla}$, $\boldsymbol{J}=-(\boldsymbol{r}\times\boldsymbol{\nabla})$ whose components close into defining relations of six dimensional Euclidean algebra $e(3)$

$$[T_j,T_k]=0,\qquad [J_j,J_k]=\epsilon_{jkl}J_l,\qquad [J_j,T_k]=\epsilon_{jkl}T_l, \tag{5}$$

the differential part of $\mathcal{L}$ can be written as

$$\boldsymbol{L}\cdot\boldsymbol{\nabla}=\boldsymbol{a}\cdot\boldsymbol{T}+\boldsymbol{b}\cdot\boldsymbol{J}. \tag{6}$$

T_j's and J_k's generate, respectively, the translation subalgebra $t(3)$ and rotation subalgebra $so(3)$ of $e(3)$ which accepts $\nabla^2=\boldsymbol{T}\cdot\boldsymbol{T}$ as its Casimir.

The first and zeroth powers of derivatives of (3) gives the following set of consistency equations

$$\boldsymbol{\nabla}L_0=\mathcal{P}\boldsymbol{L}, \tag{7}$$

$$(-\nabla^2+\mathcal{P})L_0=\boldsymbol{L}\cdot\boldsymbol{\nabla}V_0. \tag{8}$$

Equation (8) is nonlinear and the integrability conditions $\partial_j\partial_k L_0=\partial_k\partial_j L_0$ for the linear set (7) are equivalent to $\boldsymbol{L}\times\boldsymbol{\nabla}\mathcal{P}=-2\boldsymbol{b}\mathcal{P}$, where we have used the relation $\boldsymbol{\nabla}\times\boldsymbol{L}=-2\boldsymbol{b}$. Scalar multiplication of the both sides of this relation by $\boldsymbol{L}$ implies, for $\mathcal{P}\neq 0$, that

$$\boldsymbol{b}\cdot\boldsymbol{L}=\boldsymbol{a}\cdot\boldsymbol{b}=0. \tag{9}$$

Equations (7) and (8) must be solved after choosing $\boldsymbol{a}$ and $\boldsymbol{b}$ in accordance with condition (9). In doing that we shall make use of the orbit structure of $e(3)$ under the adjoint action of the Euclidean group $E(3)$ [20]. Under such a transformation, generated by

$$U=e^{\eta_1 J_3}e^{\eta_2 J_1}e^{\eta_3 J_3}e^{\boldsymbol{\xi}\cdot\boldsymbol{T}}$$

$e(3)$ has three orbit types with representatives T_3, J_3 and $\kappa_1T_3+\kappa_2J_3$, where η_i, ξ_j, κ_1 and κ_2 are real group parameters. That is, any element of $e(3)$ can be transformed by a similarity transformation U to one of the orbit representatives. Evidently, such a transformation leaves the intertwining relation form invariant; $\bar{\mathcal{L}}\bar{\mathcal{H}}_0=\bar{\mathcal{H}}_1\bar{\mathcal{L}}$, where $\bar{X}=UXU^\dagger$ and $U^{-1}=U^\dagger$ stands for the inverse of $U\in E(3)$. Thus, if we choose the differential part of $\mathcal{L}$ as one of the orbit representatives the so found potentials and L_0 will be unique up to a similarity action of $E(3)$. Noting that only the choices T_3 or J_3 for $\boldsymbol{L}\cdot\boldsymbol{\nabla}$ respect the condition (9) below we shall follow this procedure in two steps.

Step I. First we take $\boldsymbol{L}\cdot\boldsymbol{\nabla}=T_3$. In that case equation (7) gives the equations: $\partial_1L_0=0=\partial_2L_0$, $2\partial_3L_0=\mathcal{P}$ which imply $L_0=g_1(x_3)$ and $\mathcal{P}=2g_1'(x_3)$, where g_1 is an arbitrary differentiable function of x_3 (we use prime to denote derivative with respect argument). Then from the nonlinear equation (8) which takes the form $(-\partial_3^2+\mathcal{P})L_0=\partial_3V_0$, we obtain

$$V_0=V(x_1,x_2)+V_-,\qquad V_1=V(x_1,x_2)+V_+, \tag{10}$$

where

$$V_\pm=g_1^2(x_3)\pm g_1'(x_3). \tag{11}$$

Hence, we have found two isospectral Hamiltonians $H_0=-\nabla^2+V_0$ and $H_1=-\nabla^2+V_1$ that are intertwined by $\mathcal{L}_{10}=g_1(x_3)+T_3$ as follows $\mathcal{L}_{10}H_0=H_1\mathcal{L}_{10}$.

Step II. Fixing the form of H_1 found above we shall now intertwine it to an another Hamiltonian H_2 with $\mathcal{L}_{21}$. This will amount to the fact that we have three pairwise intertwined Hamiltonians

$$\mathcal{L}_{10}H_0=H_1\mathcal{L}_{10},\qquad \mathcal{L}_{21}H_1=H_2\mathcal{L}_{21},\qquad \mathcal{L}_{20}H_0=H_2\mathcal{L}_{20},$$

where $\mathcal{L}_{20} \equiv \mathcal{L}_{21}\mathcal{L}_{10}$ and the last relation is a direct result of the first two. Moreover, since each Hamiltonian will be double intertwined we will have two additional symmetries for each one.

For $H_2 = -\nabla^2 + V_2$ and $\mathcal{L}_{21} = K_0 + J_3$ the linear set of consistency equations can be read from (7) to be

$$2\partial_1 K_0 = Px_2, \qquad 2\partial_2 K_0 = -Px_1, \qquad \partial_3 K_0 = 0. \tag{12}$$

Now $P = V_2 - V_1$ and solutions are $K_0 = g_2(u)$ and $P = -2g_2'(u)/x_1^2$, where g_2 is a differentiable function of $u = x_2/x_1$. In that case the nonlinear equation is $(-\nabla^2 + P)K_0 = J_3 V_1$ and for the found K_0, P takes the form

$$\partial_u \left[(1+u^2)g_2'(u) + g_2^2(u)\right] = -x_1^2 J_3 V(x_1, x_2). \tag{13}$$

The most general form of V that makes the right-hand side of equation (13) a function of u is

$$V(x_1, x_2) = F(\rho) + \frac{1}{x_1^2} h(u), \tag{14}$$

where F and h are arbitrary functions of $\rho = (x_1^2 + x_2^2)^{1/2}$ and u respectively. Note that $J_3 F = 0$. Using (14) in (13) we see that g_2 and h have to satisfy the equation

$$\left(1+u^2\right) g_2'(u) + g_2^2(u) = \left(1+u^2\right) h(u). \tag{15}$$

Combining the results of above two steps we get the following triplet of isospectral potentials

$$V_0 = V + V_-, \qquad V_1 = V + V_+, \qquad V_2 = V_1 - \frac{2g_2'(u)}{x_1^2}. \tag{16}$$

$V_\pm$ are given by (11) and g_2, h are any solutions of equation (15). The corresponding symmetry generators are collected as follows

$$\begin{aligned}
X_0 &= \mathcal{L}_{10}^\dagger \mathcal{L}_{10} = V_- - T_3^2, \\
Y_0 &= \mathcal{L}_{20}^\dagger \mathcal{L}_{20} = \left[g_2^2 - (1+u^2)g_2' - J_3^2\right] X_0, \\
X_1 &= \mathcal{L}_{10}\mathcal{L}_{10}^\dagger = V_+ - T_3^2, \\
Y_1 &= \mathcal{L}_{21}^\dagger \mathcal{L}_{21} = g_2^2 - \left(1+u^2\right) g_2' - J_3^2, \\
X_2 &= \mathcal{L}_{21}\mathcal{L}_{21}^\dagger = g_2^2 + (1+u^2)g_2' - J_3^2, \\
Y_2 &= \mathcal{L}_{20}\mathcal{L}_{20}^\dagger = \left[g_2^2 + \left(1+u^2\right) g_2' - J_3^2\right] X_1,
\end{aligned} \tag{17}$$

where the subscripts of X_j, Y_j indicate the Hamiltonians they belong to. By construction, all these operators are factorized, have even orders (Y_2 and Y_0 are both the fourth order and X_1, Y_1, X_0, X_2 are second order) and $[H_i, X_i] = 0 = [H_i, Y_i]$; $i = 0, 1, 2$. One can also easily verify that $[X_i, Y_i] = 0$. As we have, together with the Hamiltonians, three independent, pairwise commuting symmetry generators for each Hamiltonian, equation (16) describes 3D integrable isospectral systems. From (17) we also observe that the fourth order symmetries are of the form $Y_0 = Y_1 X_0$, $Y_2 = X_2 X_1$. This is due to the fact that $\mathcal{L}_{10}$ and $\mathcal{L}_{21}$ are commuting.

We shall now introduce two additional methods which produce minimally superintegrable (having four independent symmetries) subclasses of the above integrable $3D$ systems.

Method I. In this method we shall construct an additional symmetry generator Z_1 of H_1. Since H_1 is intertwined to H_0 and H_2 the existence of such symmetry will provide $Z_0 = \mathcal{L}_{10}^\dagger Z_1 \mathcal{L}_{10}$ and $Z_2 = \mathcal{L}_{21} Z_1 \mathcal{L}_{21}^\dagger$ as new symmetry generators of H_0 and H_2. This method is another general property (independent from the dimension and Hamiltonians) of the intertwining operator idea.

As a simple realization of this method we shall take $Z_1 = \boldsymbol{c}\cdot\boldsymbol{J}$, where $\boldsymbol{c} = (c_1, c_2, c_3)$ is a constant vector. Then the condition $[Z_1, H_1] = 0$ yields the consistency equation $\boldsymbol{c}\cdot\boldsymbol{K} = 0$, where

$$K_1 = x_3\partial_2 V - x_2\partial_3 V_+(x_3), \qquad K_2 = x_3\partial_1 V - x_1\partial_3 V_+(x_3), \qquad K_3 = -J_3[\frac{h(u)}{x_1^2}], \tag{18}$$

and V_+, V are given by (11) and (14). Below three special cases are considered.

Case I. In the case of $Z_1 = J_3$ we have the equation $K_3 = 0$, which yields $h = \beta/(1+u^2)$, where β is an arbitrary constant. Since there is no restriction on F and $V_\pm$, the potentials are given by (16) with $V(\rho) = F(\rho) + \beta\rho^{-2}$. The condition (15) now is as follows

$$(1+u^2)g_2'(u) + g_2^2(u) = \beta. \tag{19}$$

The new symmetry generators of H_0 and H_2 are the following third-order operators

$$Z_0 = \mathcal{L}_{10}^\dagger Z_1 \mathcal{L}_{10} = (g_1 - T_3)J_3(g_1 + T_3) = X_0 J_3,$$
$$Z_2 = \mathcal{L}_{21} Z_1 \mathcal{L}_{21}^\dagger = (g_2 + J_3)J_3(g_2 - J_3).$$

In addition to $[Z_0, H_0] = 0 = [Z_2, H_2]$, we have

$$\begin{aligned}
&[X_1, Z_1] = 0,\\
&[Y_1, Z_1] = 4(1+u^2)g_2 g_2',\\
&[X_0, Z_0] = \mathcal{L}_{10}^\dagger [X_1, Z_1]\mathcal{L}_{10} = 0,\\
&[Y_0, Z_0] = \mathcal{L}_{10}^\dagger [Y_1, Z_1] X_1 \mathcal{L}_{10},\\
&[X_2, Z_2] = \mathcal{L}_{21}[Y_1, Z_1]\mathcal{L}_{21}^\dagger,\\
&[Y_2, Z_2] = \mathcal{L}_{21}[Y_1, Z_1] X_1 \mathcal{L}_{21}^\dagger.
\end{aligned} \tag{20}$$

Provided that $[Y_1, Z_1] \neq 0$, that is $g \neq$ const, we have $[Y_i, Z_i] \neq 0$ for $i = 0, 2$, and $[X_2, Z_2] \neq 0$. Each one of H_i corresponds to a minimally superintegrable system, with four symmetry generators (H_i, X_i, Y_i, Z_i).

Case II. If we take $Z_1 = J_2$ then the separable equation $K_2 = 0$ gives

$$V_+ = \frac{1}{2}\alpha x_3^2, \qquad h = \frac{\beta}{1+u^2} + \frac{\gamma}{u^2}, \qquad F = \frac{1}{2}\alpha\rho^2 - \frac{\beta}{\rho^2}, \tag{21}$$

where α, β, γ are arbitrary constants. In that case the potentials given by (16) are restricted to the following forms

$$V_0 = V_1 - 2g_1', \qquad V_1 = \frac{\alpha}{2}r^2 + \frac{\gamma}{x_2^2}, \qquad V_2 = V_1 - \frac{2}{x_1^2}g_2', \tag{22}$$

where $r = \left(x_1^2 + x_2^2 + x_3^2\right)^{1/2}$, and g_1, g_2 are any solutions of

$$g_1' + g_1^2 = \frac{1}{2}\alpha x_3^2, \qquad \left(1+u^2\right)g_2' + g_2^2 = \beta + \gamma + \frac{\gamma}{u^2}. \tag{23}$$

It is easy to verify that $[X_1, Z_1]$ and $[Y_1, Z_1]$ are always different from zero. The new third-order symmetry generators of H_0 and H_2 satisfy the commutators given by (20).

Case III. Finally we take $Z_1 = kJ_2 + J_1$. In that case V_+, F are the same as in (21) and

$$h = \frac{\beta}{(1+u^2)} + \frac{\gamma}{(1-ku)^2}.$$

On substituting these solutions into (16), we obtain

$$V_0 = V_1 - 2g_1', \qquad V_1 = \frac{\alpha}{2}r^2 + \frac{\gamma}{x_1^2(1-ku)^2}, \qquad V_2 = V_1 - \frac{2}{x_1^2}g_2', \tag{24}$$

where g_1 is determined from the first equation of (23) and by equation (15), g_2 is any solution of

$$\left(1+u^2\right)g_2' + g_2^2 = \beta + \gamma\frac{1+u^2}{(1-ku)^2}. \tag{25}$$

Other choices of $\boldsymbol{c}$ produce similar potentials.

Method II. By fixing the form of H_1 found in the Step I we shall now intertwine it to another Hamiltonian H_3 with $\mathcal{L}_{31}$. This will provide four pairwise intertwined Hamiltonians with three additional symmetries since each one will be three times intertwined as follows:

$$\begin{aligned}
&\mathcal{L}_{10}H_0 = H_1\mathcal{L}_{10}, \qquad \mathcal{L}_{21}H_1 = H_2\mathcal{L}_{21}, \qquad \mathcal{L}_{20}H_0 = H_2\mathcal{L}_{20},\\
&\mathcal{L}_{30}H_0 = H_3\mathcal{L}_{30}, \qquad \mathcal{L}_{31}H_1 = H_3\mathcal{L}_{31}, \qquad \mathcal{L}_{32}H_2 = H_3\mathcal{L}_{32},
\end{aligned}$$

where $\mathcal{L}_{20} \equiv \mathcal{L}_{21}\mathcal{L}_{10}$, $\mathcal{L}_{30} \equiv \mathcal{L}_{31}\mathcal{L}_{10}$ and $\mathcal{L}_{32} \equiv \mathcal{L}_{31}\mathcal{L}_{21}^{\dagger}$.

Let us take $H_3 = -\nabla^2 + V_3$ and $\mathcal{L}_{31} = M_0 + a_1T_1 + J_2$. From equation (7) the linear set of consistency equations are

$$2\partial_1 M_0 = P(a_1 - x_3), \qquad \partial_2 M_0 = 0, \qquad 2\partial_3 M_0 = Px_1, \tag{26}$$

where $P = V_3 - V_1$ and the solutions are $M_0 = g_3(v)$ and $P = -2g_3'(v)/x_1^2$, where g_3 is a differentiable function of $v = (a_1 - x_3)/x_1$. Now the nonlinear equation (corresponding to equation (8)) is $(-\nabla^2 + P)M_0 = (a_1T_1 + J_2)(V + V_+)$, and for M_0 and P found above this equation takes the form

$$\partial_v\left[\left(1+v^2\right)g_3'(v) + g_3^2(v)\right] = -x_1^2(a_1 - x_3)\partial_1\left[F(\rho) + \frac{h(u)}{x_1^2}\right] - x_1^3\partial_3 V_+(x_3), \tag{27}$$

where V_+ is given by equations (11) and we made use of equation (14). It is not hard to see that the most general forms of F, h and V_+ which make the right-hand side of equation (27) only a function of v are as follows

$$F = \mu\rho^2 - \frac{\gamma}{\rho^2} + \lambda, \qquad h = \frac{\gamma}{1+u^2} + \frac{\mu_2}{u^2} + \mu_1, \qquad V_+ = \mu(a_1 - x_3)^2 + \frac{\mu_3}{(a_1 - x_3)^2},$$

where μ, γ, μ_i; $i = 1, 2, 3$ are arbitrary constants. On substituting these in (11), (15) and (27), we see that g_1, g_2 and g_3 have to satisfy the following Riccati equations

$$\begin{aligned}
&g_1'(x_3) + g_1^2(x_3) = \mu(a_1 - x_3)^2 + \frac{\mu_3}{(a_1 - x_3)^2},\\
&\left(1+u^2\right)g_2'(u) + g_2^2(u) = \gamma + \mu_2 + \mu_1\left(1+u^2\right) + \mu_2\frac{1}{u^2},\\
&\left(1+v^2\right)g_3'(v) + g_3^2(v) = \mu_1 v^2 + \frac{\mu_3}{v^2} + \lambda_1.
\end{aligned} \tag{28}$$

Provided that g_1, g_2, g_3 are any solutions of these equations the potentials are

$$V_0 = V_1 - 2g_1'(x_3), \qquad V_1 = V + V_+, \qquad V_2 = V_1 - \frac{2g_2'(u)}{x_1^2}, \qquad V_3 = V_1 - \frac{2g_3'(v)}{x_1^2}, \tag{29}$$

where

$$V=\mu\left(x_1^2+x_2^2\right)+\left(\frac{\mu_1}{x_1^2}\right)+\left(\frac{\mu_2}{x_2^2}\right)+\lambda,$$

and λ_1, λ are arbitrary constants. The old symmetry generators X_i, Y_i, $i=0,1,2$ are given by (17) and the new ones are as follows

$$\begin{aligned}&Z_0=\mathcal{L}_{30}^{\dagger}\mathcal{L}_{30}, \qquad Z_1=\mathcal{L}_{31}^{\dagger}\mathcal{L}_{31}, \qquad Z_2=\mathcal{L}_{32}^{\dagger}\mathcal{L}_{32},\\ &X_3=\mathcal{L}_{31}\mathcal{L}_{31}^{\dagger}, \qquad Y_3=\mathcal{L}_{30}\mathcal{L}_{30}^{\dagger}, \qquad Z_3=\mathcal{L}_{32}\mathcal{L}_{32}^{\dagger}.\end{aligned} \tag{30}$$

By construction, all generators commute with the corresponding Hamiltonians, $(Y_0, Z_0, Y_2, Z_2, Y_3, Z_3)$ are of the order four (in derivative, or equivalently, in the generators of $e(3)$ algebra) and the remaining ones are the second order. H_i's are minimally superintegrable since $[X_i, Y_i]=0$, $[X_i, Z_i]\neq 0$ and $[Y_i, Z_i]\neq 0$, for $i=0,1,2$. But, because of the relations $[X_3, Y_3]\neq 0$, $[X_3, Z_3]\neq 0$ and $[Y_3, Z_3]\neq 0$ the new Hamiltonian H_3 is not even integrable. However, by applying the method I we have introduced above to the potentials given by (29), H_3 (and the other Hamiltonians) can be made maximally superintegrable (another way which may produce different potentials is to use the intertwining method once again). Finally we would like to emphasise that a hierarchy of potentials can be constructed by first linearizing the Riccati equations found above and then using the solutions of resulting $1D$ Schrödinger equations [10].

The implementation of a vibronic coupling in the context of trapped ions, and its diagonalization are reported. The specific spin-boson-like Hamiltonian model is studied exploiting its symmetries and supersymmetries. Applications are discussed.

1 Introduction

Trapped ions provide an interesting physical scenario wherein fundamental aspects of quantum mechanics may be *tested* and useful applications in *quantum computation* may be realized [1].

Generally speaking, a time dependent quadrupolar electric field is responsible for a charged particle dynamics which may be *effectively described* as the motion of a point into a quadratic potential [2]. When the harmonically confined particle is an ion, the system we obtain possesses both bosonic and fermionic degrees of freedom, the first corresponding to the ion center of mass motion, the second describing the atomic internal state, i.e. the electronic configuration. In most of the cases, in trapped ion dynamics only two atomic levels are involved, making the Pauli operator two-level system description effective.

Once the ion has been confined, acting upon it via laser field it is possible to implement vibronic couplings (i.e. involving both bosonic and fermionic degrees of freedom) practically at will [3]. Unfortunately, sometimes, the vibronic coupling problem is not solvable even if implementable.

The study of symmetries plays a central role in the analysis of trapped ion dynamical problems. Indeed, in most of the cases, symmetries provide an elegant and effective way for finding Hamiltonian eigensolutions.

In this paper we describe a trapped ion physical situation described by a Hamiltonian model possessing interesting and useful symmetries. In detail, conservation of total excitation number and rotational invariance are found. Moreover a Second Order Hidden Supersymmetry is discovered. Symmetry based diagonalization provides the possibility of writing down the time evolution concerning simple initial conditions. Interesting nonclassical behaviors like the generation of GHZ [7] states are predicted.

2 The physical system

The physical system on which we focus our attention consists in a two-level ion confined into a three dimensional isotropic trap, described by the unperturbed Hamiltonian

$$\hat{H}_0 = \frac{\hbar\omega_A}{2}\hat{\sigma}_3 + \hbar\omega_T \sum_{j=x,y,z} \hat{a}_j^\dagger \hat{a}_j,$$

where ω_A is the relevant atomic Bohr frequency, $\hat{\sigma}_3$, third component of the Pauli vector, describes the two level atomic system, ω_T is the common frequency of the degenerate trap whose annihilation (creation) operators are $\hat{a}_j$ ($\hat{a}_j^\dagger$). The total system of Bohr frequencies involving atomic transitions are given by

$$\omega = \omega_A + (m_x + m_y + m_z)\,\omega_T,$$

where m_x, m_y, m_z are relative numbers. Considering a one-dimensional dynamics, the frequency $\omega = \omega_A + m\omega_T$ is referred to as the *carrier*, *a red sideband* or a *blue sideband* depending on $m = 0$, $m < 0$ or $m > 0$ respectively.

2.1 Implementation of the Hamiltonian model

Acting upon the system via a laser field of amplitude $\vec{E}_{0,x}$, propagating along x and tuned to the second red sideband, an interaction term is added to the Hamiltonian:

$$\hat{H}_{\rm int}^{(S)} = -\vec{d}\cdot\vec{E}(\vec{r}),$$

where $\vec{d} = \vec{d}_{\pm}\hat{\sigma}_+ + \vec{d}_{\pm}^{*}\hat{\sigma}_-$ is the two-level restriction of the atomic dipole operator and $\vec{E}(\hat{\vec{r}}) = \vec{E}_{0,x}e^{i\left(k_x\hat{X}-\omega_L t\right)} + \vec{E}_{0,x}^{*}e^{-i\left(k_x\hat{X}-\omega_L t\right)}$, $\hat{X}$ being the trapped ion center of mass position operator, describes the field.

Passing to the interaction picture and expanding the exponentials using the Baker–Campbell–Hausdorff formula, the interaction Hamiltonian in the Rotating Wave approximation is

$$\hat{H}_{\rm int} = -\hbar g_x\left[e^{-\frac{\eta_L^2}{2}}\sum_{s,j=0}^{\infty}\frac{(-i\eta_x)^{s+j}}{s!j!}(\hat{a}_x^\dagger)^j\;\hat{a}_x^s e^{i(j-s)\omega_T t}e^{-i(\omega_A-\omega_L)t}\hat{\sigma}_-\right] + \text{h.c.}, \tag{1}$$

where $g_x \equiv \vec{d}_{\pm}\cdot\vec{E}_{0,x}$, $\eta_x \equiv \frac{k_x}{2\pi}\sqrt{\frac{\hbar}{\mu\omega_T}}$, μ being the mass of the ion is the so called Lamb–Dicke parameter η_x expressing the ratio between the spatial dimensions of the bosonic ground state wave function and the laser field wavelength, and hence governing the influence of the e.m. field gradient to the laser-driven trapped ion dynamics.

Retaining only stationary terms in equation (1), and observing that

$$e^{i(j-s)\omega_T t}e^{-i(\omega_A-\omega_L)t} = e^{-i(j-s-2)\omega_T t}$$

one obtains

$$\hat{H}_{\rm int} \approx -\hbar g_x\left[e^{-\frac{\eta_x^2}{2}}\sum_{j=0}^{\infty}\frac{(-i\eta_x)^{2(j+1)}}{j!(j+2)!}(\hat{a}_x^\dagger)^{j+2}\;\hat{a}_x^j\right]\hat{\sigma}_- + \text{h.c.} \tag{2}$$

In the so-called Lamb–Dicke limit, meaning that $\eta_x \ll 1$, the Hamiltonian in equation (2) may be cast in the form

$$\hat{H}_{\rm int} \approx \hbar\gamma_x\left[(\hat{a}_x^\dagger)^2\hat{\sigma}_- + (\hat{a}_x)^2\hat{\sigma}_+\right] \qquad \text{with} \quad \gamma_x \equiv g_x e^{-\frac{\eta_x^2}{2}}\frac{\eta_x^2}{2}.$$

Simultaneously acting with three laser fields tuned to the second red sideband and directed along the three x, y and z axis directions one obtains

$$\hat{H}_{\rm int} \approx \hbar\left[\gamma_x\hat{a}_x^2 + \gamma_y\hat{a}_y^2 + \gamma_z\hat{a}_z^2\right]\hat{\sigma}_+ + \text{h.c.}$$

Suitably adjusting the laser field amplitudes and the Lamb–Dicke parameters one can set equal the three γ-parameters, obtaining

$$\hat{H}_{\rm int} \approx \hbar\gamma\left(\hat{a}_x^2 + \hat{a}_y^2 + \hat{a}_z^2\right)\hat{\sigma}_+ + \text{h.c.}, \tag{3}$$

where $\gamma \equiv \gamma_x = \gamma_y = \gamma_z$.

2.2 Symmetries

The interaction picture Hamiltonian model in equation (3) describing two boson trimodal Jaynes–Cummings-like transitions, possesses interesting symmetries useful in view of $\hat{H}_{\rm int}$ diagonalization.

First of all observe that the total excitation number operator is conserved during the dynamics. Indeed, the operator

$$\hat{N} = \sum_{j=x,y,z} \hat{a}_j^\dagger \hat{a}_j + \hat{\sigma}_z + 1$$

is a constant of motion, meaning that the *phase changes*

$$\hat{a}_j \to e^{i\phi}\hat{a}_j, \qquad \hat{\sigma}_\pm \to e^{\mp i2\phi}\hat{\sigma}_\pm$$

leave unchanged the Hamiltonian operator.

Rotational invariance is the second important symmetry. In fact the center of mass angular momentum does commute with $\hat{H}_{\rm int}$:

$$[\hat{H}_{\rm int}, \hat{\vec{L}}] = \vec{0},$$

where the three components of $\hat{\vec{L}}$ are given by

$$\hat{L}_k = i(\hat{a}_j^\dagger \hat{a}_l - \hat{a}_l^\dagger \hat{a}_j) \qquad (j,l,k = x,y,z \ \text{ and cyclic}).$$

The operators $\hat{N}$, $\hat{L}^2$, $\hat{L}_z$ all commute each other and with $\hat{H}_{\rm int}$. It is worth noting that such three operators also commute with the unperturbed Hamiltonian $\hat{H}_0$, so that they really are constants of motion, in the sense that no explicit time dependence has been introduced in the passage to the interaction picture.

3 Hamiltonian model eigensolutions

To solve the interaction picture Hamiltonian eigensolution problem

$$\hat{H}_{\rm int}|\psi\rangle = E_\psi|\psi\rangle$$

observe first of all that

$$\hat{H}_{\rm int}^2 = (\hbar\gamma)^2\left[\hat{N}^2 + \hat{N} - \hat{L}^2\right]. \tag{4}$$

Such a formula determines, up to a sign, the eigenvalues of $\hat{H}_{\rm int}$ as

$$|e_{n,l}| = \hbar\gamma\sqrt{[n(n+1) - l(l+1)]},$$

$n = 2N + L + \frac{5}{2} + \hat{\sigma}_z$ and l being the quantum numbers related to the excitation number operator and to the square of the angular momentum, $N, l = 0, 1, \ldots$, $\hat{\sigma}_z = \pm 1$.

In addition to the individualization of the eigenvalue structure, equation (4) strongly suggests the existence of a Foldy–Wouthuysen-like transformation able to diagonalize the Hamiltonian model [4,5]. Such a circumstance is related to a *Second Order Hidden Supersymmetry* the system possesses.

Generally speaking, a Hamiltonian $\hat{H}_S$ is said to be supersymmetric if two operators $\hat{Q}$ and $\hat{Q}^\dagger$ exist satisfying the following algebra [6]

$$[\hat{H}_S, \hat{Q}] = [\hat{H}_S, \hat{Q}^\dagger] = 0, \qquad \{\hat{Q}, \hat{Q}^\dagger\} = \hat{H}_S, \qquad \{\hat{Q}, \hat{Q}\} = \{\hat{Q}^\dagger, \hat{Q}^\dagger\} = 0. \tag{5}$$

Starting from this, it is possible to introduce the Hermitian supercharges

$$\hat{Q}_+ = \hat{Q} + \hat{Q}^\dagger, \qquad \hat{Q}_- = i\big(\hat{Q} - \hat{Q}^\dagger\big) \tag{6}$$

satisfying the relation

$$\hat{Q}_-^2 = \hat{Q}_+^2 = \hat{H}_S. \tag{7}$$

Usually, supersymmetry is used to solve the $\hat{H}_S$ Hamiltonian eigenvalue problem or at least to predict the specific degeneration of the Hamiltonian spectrum. Nevertheless, if our attention is focused on one of the supercharges, the knowledge of relations in equation (5) and (7) proves to be useful. More in detail, a unitary transformation having $\hat{Q}_-$ as generator is able to *diagonalize* $\hat{Q}_+$ (*partially* or *completely* depending on the specific problem) and vice versa.

Since in our case we find an operator $\hat{K}_- = i\left\{\left[\hat{a}_x^2 + \hat{a}_y^2 + \hat{a}_z^2\right]\hat{\sigma}_+ - \text{h.c.}\right\}$ such that $\hat{Q}_-^2 \equiv \left(\hbar\gamma\hat{K}\right)^2 = \hat{H}_{\text{int}}^2$ we can set $\hat{Q}_+ = \hat{H}_{\text{int}}$, $\hat{Q}_- = \hbar\gamma\hat{K}$.

The unitary operator

$$\hat{U} = \exp\left(-\frac{\pi}{4}\frac{\hat{Q}_-}{|\hat{Q}_-|}\right) = \exp\left(-\frac{\pi\hat{K}}{4\left(\hat{N}^2 + \hat{N} - \hat{L}^2\right)^{1/2}}\right). \tag{8}$$

transforms $\hat{H}_{\text{int}}$ as follows:

$$\hat{U}^\dagger\hat{H}_{\text{int}}\hat{U} = \hbar\gamma\big(\hat{N}^2 + \hat{N} - \hat{L}^2\big)^{1/2}\hat{\sigma}_3. \tag{9}$$

Observe the accordance of equation (9) with equation (4) due to $\hat{\sigma}_3^2 = 1$, taking in mind that the unitary operator in equation (8) does not transform the square of $\hat{H}_{\text{int}}$ despite $\hat{H}_{\text{int}}$ itself is modified. Hence squaring equation (9) gives exactly equation (4), which is not sensible to the anti-transformation induced by $\hat{U}^\dagger$.

Standard algebraic manipulations leading to the expansion of the angular momentum eigenfunctions in the Fock basis complete the diagonalization procedure.

4 Applications and conclusive remarks

The investigated features of the Hamiltonian Model $\hat{H}_{\text{int}}$ lead to the possibility of inducing quantum dynamics satisfying certain symmetry conditions, for instance, rotational invariance. As an example assume the system prepared in the vacuum vibrational state and in the excited atomic level:

$$|\psi(t=0)\rangle = |0,0,0,+\rangle, \tag{10}$$

where the first three numbers refer to the x, y, and z vibrational excitation numbers, while the sign indicates the atomic ground $(-)$ or excited $(+)$ state.

In the light of the previous results, it is straightforward to find that once the laser interaction is turned on the system evolves in the following way:

$$|\psi(t)\rangle = \cos\left(\sqrt{6}\gamma t\right)|0,0,0,+\rangle - \frac{i}{\sqrt{3}}\sin\left(\sqrt{6}\gamma t\right)\left[|2,0,0,+\rangle + |0,2,0,+\rangle + |0,0,2,+\rangle\right]. \tag{11}$$

After a $\frac{\pi}{2}$-pulse, i.e. at the instant of time t_0 such that $\sqrt{6}\gamma t_0 = \frac{\pi}{2}$, up to a global phase factor, the system is found to be in the GHZ state [7]

$$|\psi(t_0)\rangle = \frac{1}{\sqrt{3}}|2,0,0,+\rangle + |0,2,0,+\rangle + |0,0,2,+\rangle.$$

The importance of such a state relies in its applications in the study of the Bell's inequality violations [7]. In passing we observe that, as expected, starting from the spherically symmetric wavefunction given in equation (10), the dynamics preserves such a symmetry at any instant of time. As another example consider an non-spherically symmetric initial state which distinguishes the z-direction from the other two. Let be

$$|\psi(t=0)\rangle = |0,0,2,-\rangle.$$

The relevant time evolution is given by

$$|\psi(t)\rangle = \frac{1}{3}\big[\cos\big(\sqrt{6}\gamma t\big)+2\big]|0,0,2,-\rangle + \frac{1}{3}\big[\cos\big(\sqrt{6}\gamma t\big)-1\big]\left[|2,0,0,-\rangle + |0,2,0,-\rangle\right] - \frac{i}{\sqrt{3}}\sin\big(\sqrt{6}\gamma t\big)|0,0,0,+\rangle. \tag{12}$$

Due to the fact that $\{|2,0,0,-\rangle, |0,2,0,-\rangle, |0,0,2,-\rangle, |0,0,0,+\rangle\}$ is an excitation number of invariant subspace, the states involved in the two considered dynamics, the ones in equation (11) and equation (12), are the same. Nevertheless, the weights are significantly different. In particular, as well and easily seen, the initial symmetry breaking is preserved by the time evolution. Indeed, for instance, despite $|0,0,0,+\rangle$ appears, no instant of time exists when the state $|\psi(t)\rangle$ coincides with it.

Summarizing, in this paper we have described the trapped ion physical scenario and focused our attention to a specific experimental configuration (three lasers suitably tuned and so on) corresponding to a second order vibronic Jaynes–Cummings like interaction model.

The Hamiltonian exhibits interesting and useful symmetry properties: total excitation number conservation, spherical invariance and a hidden supersymmetry. Exploiting all such features we succeed in finding Hamiltonian Model eigensolutions and, hence, in describing the dynamics it is responsible for, with respect to some simple initial conditions.

As expected, the degree of spherical symmetry is found to be preserved during all the time evolution. Moreover, in correspondence to a vacuum vibrational state initial state, a GHZ state is obtained.

Generalized Self-Duality in Superfield Formalism

Anatoli PAVLYUK

Bogolyubov Institute for Theoretical Physics, 14b Metrologichna Str., 03143 Kyiv, Ukraine
E-mail: *a_pavlyuk@ukr.net*

The generalized super self-duality equations for $N = 2$ Super Yang–Mills theory in $N = 1$ superspace, which are first-order equations, in terms of component fields as well as in terms of superfields are presented.

In the pure $SU(2)$ Yang–Mills theory the self-duality equations read

$$iF_{mn} = \widetilde{F}_{mn} \equiv \frac{1}{2}\epsilon_{mnkl}F^{kl}, \tag{1}$$

where

$$F_{mn} = \partial_m V_n - \partial_n V_m + ig[V_m, V_n], \qquad \eta_{mn} = \mathrm{diag}\,(-1, 1, 1, 1).$$

Going from vector indices $(m, n = 0, 1, 2, 3)$ to spinor indices $(\alpha, \beta = 1, 2)$

$$x_m \to x_{\alpha\dot{\alpha}} = \sigma^m{}_{\alpha\dot{\alpha}} x_m,$$

where $\sigma^m = (-1, \vec{\sigma})$, (1 is a unit 2×2 matrix, $\vec{\sigma}$ are Pauli matrices), one obtains the Yang–Mills strength in the following form

$$F_{\alpha\dot{\alpha},\beta\dot{\beta}} \equiv \sigma^m{}_{\alpha\dot{\alpha}}\sigma^n{}_{\beta\dot{\beta}}F_{mn} = \frac{1}{2}\varepsilon_{\alpha\beta}f_{\dot{\alpha}\dot{\beta}} + \frac{1}{2}\varepsilon_{\dot{\alpha}\dot{\beta}}f_{\alpha\beta},$$

where

$$f_{\dot{\alpha}\dot{\beta}} \equiv \epsilon^{\alpha\gamma}F_{\gamma\dot{\alpha},\alpha\dot{\beta}}, \qquad f_{\alpha\beta} \equiv \epsilon^{\dot{\alpha}\dot{\gamma}}F_{\alpha\dot{\gamma},\beta\dot{\alpha}}.$$

Now the self-duality equations (1) take the form

$$f_{\alpha\beta} = 0. \tag{2}$$

The two-spinor indices are raised and lowered by means of the two-dimensional Levi-Civita tensors

$$\varepsilon^{12} = -\varepsilon_{12} = \varepsilon^{\dot{1}\dot{2}} = -\varepsilon_{\dot{1}\dot{2}} = +1.$$

The raising and lowering of spinor indices are defined by

$$\lambda^\alpha = \varepsilon^{\alpha\beta}\lambda_\beta, \qquad \lambda^{\dot{\alpha}} = \varepsilon^{\dot{\alpha}\dot{\beta}}\lambda_{\dot{\beta}}, \qquad \lambda_\alpha = \varepsilon_{\alpha\beta}\lambda^\beta, \qquad \lambda_{\dot{\alpha}} = \varepsilon_{\dot{\alpha}\dot{\beta}}\lambda^{\dot{\beta}}.$$

In the $SU(2)$ $N = 1$ Super Yang–Mills theory [1]

$$L = \mathrm{Tr}\left\{-\frac{1}{4}F_{mn}F^{mn} - i\bar{\lambda}\overline{\sigma}^m\mathcal{D}_m\lambda + \frac{1}{2}D^2\right\}, \tag{3}$$

where with help of supersymmetric transformations of (2) one obtains the system of super self-duality equations in component fields [2]

$$f_{\alpha\beta} = 0, \qquad D = 0, \qquad \mathcal{D}_{\alpha\dot{\alpha}}\bar{\lambda}^{\dot{\alpha}} = 0, \qquad \lambda_\alpha = 0. \tag{4}$$

The system of super self-duality equations (4) is a supersymmetric generalization of self-duality equations (2) and satisfies the equations of motion of theory (3). It is invariant under $N = 1$ supersymmetric transformations.

Let us proceed to the $N = 2$ supersymmetric Yang–Mills theory in $N = 1$ superspace, which is described by vector and scalar multiplets of component fields,

$$V = (V_m; \lambda_\alpha; \bar\lambda_{\dot\alpha}; D), \qquad \Phi = (A, B; \psi_\alpha; \bar\psi_{\dot\alpha}; F, G).$$

Gauge-invariant supersymmetric Lagrangian of $N = 2$ Yang–Mills theory in $N = 1$ superspace, whose fields belong to the adjoint representation of $SU(2)$ gauge group, has the form

$$\begin{aligned} L = \mathrm{Tr}\Big\{ & -\frac{1}{4}F_{mn}F^{mn} - \frac{1}{2}\mathcal{D}_m A\mathcal{D}^m A - \frac{1}{2}\mathcal{D}_m B\mathcal{D}^m B + igD[A,B] \\ & - i\bar\lambda\overline{\sigma}^m\mathcal{D}_m\lambda - i\bar\psi\overline{\sigma}^m\mathcal{D}_m\psi + ig(A+iB)\{\lambda^\alpha,\psi_\alpha\} \\ & + ig(A-iB)\{\bar\lambda_{\dot\alpha},\bar\psi^{\dot\alpha}\} + \frac{1}{2}D^2 + \frac{1}{2}F^2 + \frac{1}{2}G^2\Big\}. \end{aligned} \tag{5}$$

The equations of motion of theory (5) are as follows

$$\begin{aligned} & \varepsilon^{\dot\alpha\dot\gamma}\mathcal{D}_{\alpha\dot\gamma}f_{\dot\alpha\dot\beta} + \varepsilon^{\beta\gamma}\mathcal{D}_{\gamma\dot\beta}f_{\alpha\beta} + 4g\big(\{\lambda_\alpha,\bar\lambda_{\dot\beta}\} + \{\psi_\alpha,\bar\psi_{\dot\beta}\}\big) \\ & \qquad - ig\big([A-iB,\mathcal{D}_{\alpha\dot\beta}(A+iB)] + [A+iB,\mathcal{D}_{\alpha\dot\beta}(A-iB)]\big) = 0, \\ & \mathcal{D}_{\alpha\dot\beta}\mathcal{D}^{\alpha\dot\beta}(A-iB) - 4ig\{\lambda^\alpha,\psi_\alpha\} - 2g[D,A-iB] = 0, \\ & \mathcal{D}_{\alpha\dot\beta}\mathcal{D}^{\alpha\dot\beta}(A+iB) - 4ig\{\bar\lambda_{\dot\alpha},\bar\psi^{\dot\alpha}\} + 2g[D,A+iB] = 0, \\ & D + ig[A,B] = 0, \qquad F = G = 0, \\ & \mathcal{D}^{\alpha\dot\beta}\lambda_\alpha - g[\bar\psi^{\dot\beta},A-iB] = 0, \qquad \mathcal{D}_{\alpha\dot\beta}\bar\lambda^{\dot\beta} - g[\psi_\alpha,A+iB] = 0, \\ & \mathcal{D}^{\alpha\dot\beta}\psi_\alpha + g[\bar\lambda^{\dot\beta},A-iB] = 0, \qquad \mathcal{D}_{\alpha\dot\beta}\bar\psi^{\dot\beta} + g[\lambda_\alpha,A+iB] = 0. \end{aligned} \tag{6}$$

Lagrangian (5) and the equations of motion (6) are invariant under the following $N = 1$ supersymmetric transformations

$$\begin{aligned} & \delta_\xi(A-iB) = 2\xi^\alpha\psi_\alpha, \qquad \delta_\xi(A+iB) = 2\bar\xi_{\dot\alpha}\bar\psi^{\dot\alpha}, \\ & \delta_\xi V_{\alpha\dot\alpha} = -2i(\xi_\alpha\bar\lambda_{\dot\alpha} + \bar\xi_{\dot\alpha}\lambda_\alpha), \qquad \delta_\xi D = -\xi^\alpha\mathcal{D}_{\alpha\dot\alpha}\bar\lambda^{\dot\alpha} + \bar\xi_{\dot\alpha}\mathcal{D}^{\alpha\dot\alpha}\lambda_\alpha, \\ & \delta_\xi(F+iG) = 2i\bar\xi_{\dot\beta}\big(\mathcal{D}^{\alpha\dot\beta}\psi_\alpha + g[\bar\lambda^{\dot\beta},A-iB]\big), \\ & \delta_\xi(F-iG) = 2i\xi^\alpha\big(\mathcal{D}_{\alpha\dot\beta}\bar\psi^{\dot\beta} + g[\lambda_\alpha,A+iB]\big), \\ & \delta_\xi\lambda_\alpha = \frac{1}{2}\xi^\beta f_{\alpha\beta} + i\xi_\alpha D, \qquad \delta_\xi\bar\lambda_{\dot\alpha} = \frac{1}{2}\bar\xi^{\dot\beta}f_{\dot\alpha\dot\beta} - i\bar\xi_{\dot\alpha}D, \\ & \delta_\xi\psi_\alpha = i\bar\xi^{\dot\alpha}\mathcal{D}_{\alpha\dot\alpha}(A-iB) + \xi_\alpha(F+iG), \\ & \delta_\xi\bar\psi_{\dot\alpha} = -i\xi^\alpha\mathcal{D}_{\alpha\dot\alpha}(A+iB) + \bar\xi_{\dot\alpha}(F-iG), \end{aligned} \tag{7}$$

where ξ_α, $\bar\xi_{\dot\alpha}$ are the parameters of $N = 1$ supersymmetric transformations.

In the theory (5) there is no supersymmetric generalization of self-duality equations (2) to super self-duality equations. We propose the system of first-order equations, which satisfies the second-order equations of motion (6) [3]

$$\begin{aligned} & f_{\alpha\beta} = 2igc_{\alpha\beta}[A,B], \\ & \mathcal{D}_{1\dot\alpha}(A-iB) = k_1\mathcal{D}_{2\dot\alpha}(A-iB), \qquad \mathcal{D}_{1\dot\alpha}(A+iB) = k_2\mathcal{D}_{2\dot\alpha}(A+iB), \\ & D + ig[A,B] = 0, \qquad F = G = 0, \qquad \mathcal{D}_{\alpha\dot\beta}\bar\lambda^{\dot\beta} - g[\psi_\alpha,A+iB] = 0, \\ & \mathcal{D}^{\alpha\dot\beta}\psi_\alpha + g[\bar\lambda^{\dot\beta},A-iB] = 0, \qquad \lambda_\alpha = \bar\psi_{\dot\alpha} = 0, \qquad \psi_1 = k_1\psi_2, \end{aligned} \tag{8}$$

where constant complex bispinor coefficients $c_{\alpha\beta}$ are symmetric and unimodular

$$c_{\alpha\beta} = c_{\beta\alpha}, \qquad \det \|c_{\alpha\beta}\| \equiv c_{11} \cdot c_{22} - c_{12}^2 \equiv \frac{1}{2} c^{\alpha\beta} c_{\alpha\beta} = 1.$$

The coefficients k_1, k_2 can be calculated through $c_{\alpha\beta}$:

$$k_1 = \frac{c_{11}}{c_{12} - i} = \frac{c_{12} + i}{c_{22}}, \qquad k_2 = \frac{c_{11}}{c_{12} + i} = \frac{c_{12} - i}{c_{22}}.$$

In turn, the coefficients $c_{\alpha\beta}$ are expressed through k_1, k_2:

$$c_{11} = \frac{2ik_1k_2}{k_1 - k_2}, \qquad c_{12} = \frac{i(k_1 + k_2)}{k_1 - k_2}, \qquad c_{22} = \frac{2i}{k_1 - k_2}.$$

The system of first-order equations (8) is invariant under $N = 1$ supersymmetric transformations (7) in the subspace of the parameters of transformations, which is defined by the following condition

$$\xi_1 = k_2 \xi_2.$$

In the case of vanishing component fields of scalar multiplet

$$A = B = \psi_\alpha = \bar{\psi}_{\dot\alpha} = F = G = 0$$

the system (8) reduces to the system of super self-duality equations (4). Because of these properties we call (8) the system of super quasi-self-duality equations. Considering only bosonic sector of theory (5), we obtain from (8) the system of quasi-self-duality equations. The concept of quasi-self-duality was introduced by V.A. Yatsun [4, 5].

The fact that the solutions of the system (8) are the solutions of the equations of motion (6) is immediately proved by taking covariant derivatives from the first three equations of the system (8). To see this we take a covariant derivative $\epsilon^{\beta\gamma}\mathcal{D}_{\gamma\dot\beta}$ from the first equation of the system (8):

$$f_{\alpha\beta} - g c_{\alpha\beta}[A - iB, A + iB] = 0.$$

Then by using the second and third equations of the system (8) and taking into account the Bianchi identity $\epsilon^{\dot\alpha\dot\gamma}\mathcal{D}_{\alpha\dot\gamma} f_{\dot\alpha\dot\beta} = \epsilon^{\beta\gamma}\mathcal{D}_{\gamma\dot\beta} f_{\alpha\beta}$ and $\lambda_\alpha = \bar{\psi}_{\dot\alpha} = 0$, we obtain the first equation of the system (6). Taking a covariant derivative $\mathcal{D}^{1\dot\alpha}$ and $\mathcal{D}^{2\dot\alpha}$ from the second and third equations of (8) and using the first equation of this system, we obtain corresponding equations of motion from the system (6).

A superfield formulation of the super quasi-self-duality equations (8) can be obtained in the superspace $(x^m; \theta_\alpha; \bar\theta_{\dot\alpha})$ with the fixed Grassmann variable $\theta_1 = k_2\theta_2$. A spinor chiral superfield is defined by [6]

$$W_\alpha = -\frac{1}{8g}\overline{\mathcal{D}\mathcal{D}}\big(e^{-2gV}\mathcal{D}_\alpha e^{2gV}\big),$$

where V is a vector superfield in the Wess–Zumino gauge

$$V = -\theta^\alpha\bar\theta^{\dot\alpha}V_{\alpha\dot\alpha} + i\theta\theta\bar\theta\bar\lambda - i\bar\theta\bar\theta\theta\lambda + \frac{1}{2}\theta\theta\bar\theta\bar\theta D,$$

and the covariant derivatives are

$$\mathcal{D}_\alpha = \frac{\partial}{\partial\theta^\alpha} + i\bar\theta^{\dot\alpha}\partial_{\alpha\dot\alpha}, \qquad \overline{\mathcal{D}}_{\dot\alpha} = -\frac{\partial}{\partial\bar\theta^{\dot\alpha}} - i\theta^\alpha\partial_{\alpha\dot\alpha}.$$

In component fields it is given by

$$W_\alpha = -i\lambda_\alpha - \frac{i}{2}\theta^\beta(f_{\alpha\beta} + 2i\varepsilon_{\alpha\beta}D) + \theta^\beta\bar\theta^{\dot\beta}\partial_{\beta\dot\beta}\lambda_\alpha + \theta\theta\mathcal{D}_{\alpha\dot\beta}\bar\lambda^{\dot\beta}$$
$$- \frac{1}{4}\theta\theta\bar\theta^{\dot\alpha}\epsilon^{\beta\gamma}\partial_{\gamma\dot\alpha}(f_{\alpha\beta} + 2i\varepsilon_{\alpha\beta}D) - \frac{i}{4}\theta\theta\bar\theta\bar\theta\Box\lambda_\alpha, \tag{9}$$

where

$$\Box = \partial_m\partial^m = -\frac{1}{2}\partial_{\alpha\dot\beta}\partial^{\alpha\dot\beta}.$$

The Hermitian adjoint superfield is

$$\big(W_\alpha\big)^\dagger = \overline{W}_{\dot\alpha} = -\frac{1}{8g}\mathcal{D}\mathcal{D}\big(\overline{\mathcal{D}}_{\dot\alpha}e^{2gV}\cdot e^{-2gV}\big).$$

A scalar chiral superfield is defined by the condition $\overline{\mathcal{D}}_{\dot\alpha}\Phi = 0$ and in components has the form

$$\Phi = \frac{1}{2}(A - iB) + \theta\psi + \frac{i}{2}\theta^\alpha\bar\theta^{\dot\alpha}\partial_{\alpha\dot\alpha}(A - iB) + \frac{i}{2}\theta\theta\bar\theta^{\dot\alpha}\partial_{\alpha\dot\alpha}\psi^\alpha$$
$$+ \frac{1}{8}\theta\theta\bar\theta\bar\theta\Box(A - iB) + \frac{1}{2}\theta\theta(F + iG).$$

Consequently, its Hermite conjugate $\Phi^\dagger$ is given by $\mathcal{D}_\alpha\Phi^\dagger = 0$. The gauge-covariant spinor derivatives are

$$\nabla_\alpha = \mathcal{D}_\alpha + i[\mathcal{A}_\alpha, \cdot\,], \qquad \nabla_{\dot\alpha} = \overline{\mathcal{D}}_{\dot\alpha} + i[\mathcal{A}_{\dot\alpha}, \cdot\,],$$

where

$$\mathcal{A}_\alpha = -ie^{-2gV}\mathcal{D}_\alpha e^{2gV}, \qquad \mathcal{A}_{\dot\alpha} = i\overline{\mathcal{D}}_{\dot\alpha}e^{2gV}\cdot e^{-2gV}.$$

The system of super quasi-self-duality equations (8) can be presented in superfield formalism in the following form

$$\nabla_\alpha W_\beta = -2ig(c_{\alpha\beta} - i\varepsilon_{\alpha\beta})[\Phi, \Phi^\dagger - 2g[V, \Phi^\dagger]],$$
$$\nabla_1\Phi = k_1\nabla_2\Phi, \qquad \nabla_{\dot\alpha}\Phi^\dagger = 0, \qquad \theta_1 = k_2\theta_2. \tag{10}$$

The system of superfield quasi-self-duality equations (10) includes the equation for Grassmann coordinates

$$\theta_1 = k_2\theta_2. \tag{11}$$

To obtain component system (8) from superfield system (10) we have to calculate first three superfield equations of (10) in component fields, and only after that we have to impose the condition (11) on the Grassmann variables in these superfield equations.

A four dimensional non-trivial extension of the Poincaré algebra different from supersymmetry is explicitly studied. Representation theory is investigated and an invariant Lagrangian is exhibited. Some discussion on the Noether theorem is also given.

1 Introduction

The concept of symmetries is a central tool in the description of physical systems. One of the main questions is, of course, what are the mathematical structures which are useful in describing the laws of physics, and, in particular, useful in particle physics or quantum field theories. Among others, finite-dimensional Lie algebras become essential for the description of space-time symmetries and fundamental interactions. On the other hand, it was the discovery of supersymmetry in relativistic quantum field theory or as a possible non-trivial extension of Poincaré invariance [1] which gave rise to the concept of Lie superalgebras. One natural question one should address is the possibility to weigh up, in relativistic quantum field theory, algebraic structures which are not Lie (super)algebras. *A priori* this should be a difficult task. Indeed, according to the Noether theorem, to all (Noetherian) symmetries correspond a conserved currents. These symmetries are then generated by charges which are expressed in terms of the fields. But, having two kinds of fields, of integer or half-integer spin, which, by spin-statistics theorem will close with commutators or anticommutators, *a priori* one should obtain only Lie and Lie superalgebras. Furthermore, the Coleman–Mandula [2] and the Haag–Lopuszanski–Sohnius [3] theorems state that within the framework of Lie algebras one obtains only the description of space-time and/or internal symmetries, while within Lie superalgebras supersymmetry is the *unique* non-trivial extension of the Poincaré algebra which is possible.

But, if one examines the hypotheses of the above theorems, one sees that it is possible to imagine symmetries which go beyond supersymmetry. Several possibilities have been considered in the literature, the intuitive idea being that the generators of the Poincaré algebra are obtained as an appropriate product of more fundamental additional symmetries. These new generators are in an appropriate representation of the Poincaré algebra.

In this contribution we would like to study one of the possible non-trivial extension of the Poincaré algebra, different from supersymmetry, named fractional supersymmetry (FSUSY) [4–20] and its associated underlying algebraic structure named F-Lie algebras [17,19]. In supersymmetric theories, the extensions of the Poincaré algebra are obtained from a "square root" of the translations, "$QQ \sim P$". In this paper, new algebras are obtained from yet higher order roots. We mainly focus on the simplest alternative where "cubic roots" are involved "$QQQ \sim P$" [20]. It is important to stress that such structures are not Lie (super)algebras and as such escape *a priori* the Coleman–Mandula [2] as well as the Haag–Lopuszanski–Sohnius [3] no-go theorems. Furthermore, as far as we know, no no-go theorem associated to such types of extensions has been considered in the literature. This can open interesting possibilities to search for a field theoretic realization of a non-trivial extension of the Poincaré algebra that *is not the supersymmetric one.*

The aim of this paper is to summarize some results already obtained in [20], *i.e.* to construct explicitly the first field theoretic construction in $(1+3)$ dimensions of an FSUSY with $F = 3$,

which we will refer to as *cubic supersymmetry*, or 3SUSY. Representation of our algebra leads to fermionic or bosonic multiplets. We find that the fermion multiplets are made of three definite chirality fermions that are degenerate in mass, while the boson multiplets contain Lorentz scalars, vectors and two-forms. A striking feature for the boson multiplets is the compatibility of 3SUSY with gauge symmetry only when the latter is gauge fixed in the usual way. Some discussions on Noether theorem in relation with 3SUSY are also given. The paper is organized as follow. In Section 2 some results on the algebraic extension of the Poincaré algebra are given. In Section 3 representations of the 3SUSY algebra are exhibited. In Section 4, we construct an invariant Lagrangian in the case of the bosonic multiplet. Section 5 is devoted to some discussions on Noether theorem. Finally, some conclusions are given in Section 6.

2 Non trivial extension of the Poincaré algebra

A natural generalization of Lie (super)algebras which is relevant for the algebraic description of FSUSY was defined in [18, 19] and called an F-Lie algebra. An $F-$Lie algebra admits a $\mathbb{Z}_F$-gradation, the zero-graded part being a Lie algebra. An F-fold symmetric product (playing the role of the anticommutator in the case $F = 2$) expresses the zero graded part in terms of the non-zero graded part. The first examples of F-Lie algebras where infinite-dimensional [17]. It was then established that one of these examples of infinite-dimensional algebras was relevant to apply FSUSY on relativistic anyons in $(1 + 2)D$ [16]. Later on, it was shown how to construct finite-dimensional F-Lie algebras with $F > 2$ by an inductive process starting from Lie algebras and Lie superalgebras [19]. Among these families of examples one can identify F-Lie algebras that could generate extensions of the Poincaré algebra. One of these examples is given by

$$\mathfrak{g} = \mathfrak{sp}(4, \mathbb{R}) \oplus \mathrm{ad}\,(\mathfrak{sp}(4, \mathbb{R})) \tag{1}$$

with $\mathrm{ad}\,(\mathfrak{sp}(4, \mathbb{R}))$ the adjoint representation of $\mathfrak{sp}(4, \mathbb{R})$. $\mathfrak{g}_0 = \mathfrak{sp}(4, \mathbb{R})$ is the zero graded part ("bosonic") of $\mathfrak{g}$ and $\mathfrak{g}_1 = \mathrm{ad}\,(\mathfrak{sp}(4, \mathbb{R}))$ is the graded part of the algebra. If we denote J_a, $a = 1, \ldots, 10$ a basis of $\mathfrak{sp}(4, \mathbb{R})$, A_a the corresponding basis for $\mathrm{ad}\,(\mathfrak{sp}(4, \mathbb{R}))$, and $g_{ab} = \mathrm{Tr}\,(A_a A_b)$ the Killing form of $\mathfrak{sp}(4, \mathbb{R})$, then the F-Lie algebra of order 3 $\mathfrak{g}$ reads [19, 20][1]

$$[J_a, J_b] = f_{ab}{}^c J_c, \qquad [J_a, A_b] = f_{ab}{}^c A_c, \qquad \{A_a, A_b, A_c\} = g_{ab} J_c + g_{ac} J_b + g_{bc} J_a, \tag{2}$$

where $f_{ab}{}^c$ are the structure constant of $\mathfrak{sp}(4, \mathbb{R})$ and $\{A_a, A_b, A_c\}$ is given by the symmetric three-fold product $A_a A_b A_c + A_a A_c A_b + A_b A_c A_a + A_b A_a A_c + A_c A_a A_b + A_c A_b A_a$.

Observing that $\mathfrak{so}(1, 3) \subset \mathfrak{so}(2, 3) \cong \mathfrak{sp}(4)$, and that the $(1 + 3)D$ Poincaré algebra is related to $\mathfrak{sp}(4)$ through an Inönü–Wigner contraction, from the F-Lie algebra (2), an extension of the Poincaré algebra can be constructed [20]:

$$\begin{aligned}
&[L_{mn}, L_{pq}] = \eta_{nq} L_{pm} - \eta_{mq} L_{pn} + \eta_{np} L_{mq} - \eta_{mp} L_{nq}, \qquad [L_{mn}, L_p] = \eta_{np} P_m - \eta_{mp} P_n, \\
&[L_{mn}, Q_p] = \eta_{np} Q_m - \eta_{mp} Q_n, \qquad [P_m, Q_n] = 0, \\
&\{Q_m, Q_n, Q_r\} = \eta_{mn} P_r + \eta_{mr} P_n + \eta_{rn} P_m,
\end{aligned} \tag{3}$$

where η_{mn} is the Minkowski metric, L_{mn}, P_m are the Poincaré generators and Q_m are the "supercharges" in the vector representation of $\mathfrak{so}(1, 3)$.

3 Representations

Representations of (3) were also studied in [20]. It turns out that, for algebras defined by cubic relations, the situation is a more difficult task than in usual supersymmetric theories. Indeed,

[1] In addition to these relations, one has also some appropriate Jacobi identities. See [18–20] for details.

representations of supersymmetry are related to representations theory of the well-known Clifford algebra, while representation theory of FSUSY is related to Clifford algebras of polynomial [21]. To obtain representations of the algebra (3), we rewrite the RHS of the trilinear bracket as $\{Q_m, Q_n, Q_r\} = f_{mnr} = f_{mnr}{}^s P_s$, with $f_{mnr}{}^s = \eta_{mn}\delta_r{}^s + \eta_{mr}\delta_n{}^s + \eta_{rn}\delta_m{}^s$. This substitution shows that the cubic polynomial $f(v^0, v^1, v^2, v^3) = f_{mnr}v^m v^n v^r = 3(v.P)(v.v)$ is associated to the symmetric tensor f_{mnr}. Moreover, the algebra (3) simply means that $f(v) = (v^m Q_m)^3$, as can be verified by developing the cube and identifying all terms, using the trilinear bracket. The generators Q_m, $m = 0, \dots, 3$, which are associated with the variables v^m, $m = 0, \dots, 3$, then generate an extension of the Clifford algebra called Clifford algebra of the polynomial f (denoted $\mathcal{C}_f$). This means that the Q's allow to "linearize" f. The general representation theory of $\mathcal{C}_f$ is not known, however, a systematic method to represent $\mathcal{C}_f$ by appropriate matrices has been given [22]. For the algebra (3) one obtains [20]

$$Q_m = \begin{pmatrix} 0 & \Lambda^{1/3}\gamma_m & 0 \\ 0 & 0 & \Lambda^{1/3}\gamma_m \\ \Lambda^{-2/3}P_m & 0 & 0 \end{pmatrix}. \tag{4}$$

with γ_m being the $4D$ Dirac matrices and $P_m = -i\frac{\partial}{\partial x^m}$. It is interesting to notice that because P is dimensionful, a parameter with a mass dimension appears naturally in (4).

The Q being in the vector representation of $\mathfrak{so}(1,3)$, it is easy to see that

$$J_{mn} = \frac{1}{4}(\gamma_m\gamma_n - \gamma_n\gamma_m) + i(x_m P_n - x_n P_m) \tag{5}$$

are the appropriate Lorentz generators acting on Q: $[J_{mn}, Q_r] = \eta_{nr}Q_m - \eta_{mr}Q_m$.

Introducing the $4D$ Dirac matrices in the Weyl representation, $\gamma_m = \begin{pmatrix} 0 & \sigma_m \\ \bar{\sigma}_m & 0 \end{pmatrix}$, with $\sigma_{m\,\alpha\dot{\alpha}} = (1, \sigma_i)$, $\bar{\sigma}_m{}^{\dot{\alpha}\alpha} = (1, -\sigma_i)$ and σ_i the Pauli matrices (the convention for dotted and undotted indices are those conventionally used in SUSY, – see *e.g.* appendix B of [20]), shows that the representation (4) is reducible and leads to the two inequivalent $6D$ representations:

$$Q_m = \begin{pmatrix} 0 & \Lambda^{1/3}\sigma_m & 0 \\ 0 & 0 & \Lambda^{1/3}\bar{\sigma}_m \\ \Lambda^{-2/3}P_m & 0 & 0 \end{pmatrix}, \qquad Q_m = \begin{pmatrix} 0 & \Lambda^{1/3}\bar{\sigma}_m & 0 \\ 0 & 0 & \Lambda^{1/3}\sigma_m \\ \Lambda^{-2/3}P_m & 0 & 0 \end{pmatrix}. \tag{6}$$

In this representation the trilinear part of the algebra (3) is realized as

$$\begin{aligned} &Q_mQ_nQ_r + Q_mQ_rQ_n + Q_nQ_mQ_r + Q_nQ_rQ_m + Q_rQ_mQ_n + Q_rQ_nQ_m \\ &\quad = \eta_{mn}P_r + \eta_{nr}P_m + \eta_{mr}P_n. \end{aligned} \tag{7}$$

3.1 Fermionic multiplet

As usual, the content of the representation is not only specified by the form of the matrix representation, but also by the behavior of the vacuum under Lorentz transformations. If we denote by Ω the vacuum, which is in some specified representation of the Lorentz algebra, with Σ_{mn} the corresponding Lorentz generators, then J_{mn} given in (5) is replaced by $J_{mn} + \Sigma_{mn}$. In the case, where Ω is a Lorentz scalar, one sees that the multiplet of the representations (6) contains two left-handed and one right-handed fermions for the first matrices, while the multiplet of the representation contains one left-handed and two right-handed fermions for the second matrices. These two multiplets are CPT conjugate. In the first case, if we denote $\mathbf{\Psi} = \begin{pmatrix} \psi_{1\alpha} \\ \bar{\psi}_2^{\dot{\alpha}} \\ \psi_{3\alpha} \end{pmatrix}$,

then under a 3SUSY transformation we have $\delta_\varepsilon \mathbf{\Psi} = \varepsilon^m Q_m \mathbf{\Psi}$ and we obtain

$$\delta_\varepsilon \psi_{1\alpha} = \varepsilon^n \Lambda^{1/3} \sigma_{n\alpha\dot\alpha} \bar\psi_2{}^{\dot\alpha}, \qquad \delta_\varepsilon \bar\psi_2{}^{\dot\alpha} = \varepsilon^n \Lambda^{1/3} \bar\sigma_n{}^{\dot\alpha\alpha} \psi_{3\alpha}, \qquad \delta_\varepsilon \psi_{3\alpha} = \varepsilon^n \Lambda^{-2/3} P_n \psi_{1\alpha} \tag{8}$$

with ε a pure imaginary number.

3.2 Bosonic multiplet

In the previous subsection, we were considering the fundamental representation associated to the matrices (6), say $\mathbf{\Psi} = \begin{pmatrix} \psi_{1\alpha} \\ \bar\psi_2{}^{\dot\alpha} \\ \psi_{3\alpha} \end{pmatrix}$ and $\mathbf{\Psi}' = \begin{pmatrix} \bar\psi_1'{}^{\dot\alpha} \\ \psi'_{2\alpha} \\ \bar\psi_3'{}^{\dot\alpha} \end{pmatrix}$, *i.e.* with the vacuum Ω in the trivial representation of the Lorentz algebra. In this section boson multiplets, will be introduced, corresponding to a vacuum in the spinor representations of the Lorentz algebra. This means that four types of boson multiplets can be introduced: $\mathbf{\Psi} \otimes \Omega^\alpha$, $\mathbf{\Psi}' \otimes \Omega^\alpha$, with Ω^α a left-handed spinor and $\mathbf{\Psi} \otimes \bar\Omega_{\dot\alpha}$, $\mathbf{\Psi}' \otimes \bar\Omega_{\dot\alpha}$ with $\bar\Omega_{\dot\alpha}$ a right-handed spinor.

For the multiplet associated to $\mathbf{\Psi}^\beta = \mathbf{\Psi} \otimes \Omega^\beta$, we have $\mathbf{\Psi}^\beta = \begin{pmatrix} \rho_{1\alpha}{}^\beta \\ \bar\rho_2{}^{\dot\alpha\beta} \\ \rho_{3\alpha}{}^\beta \end{pmatrix}$ and for the one (CPT conjugate of the previous) $\mathbf{\Psi}_{\dot\beta} = \mathbf{\Psi}' \otimes \Omega_{\dot\beta} = \begin{pmatrix} \bar\rho_1{}^{\dot\alpha}{}_{\dot\beta} \\ \rho_{2\alpha\dot\beta} \\ \bar\rho_3{}^{\dot\alpha}{}_{\dot\beta} \end{pmatrix}$. The transformation under 3SUSY is $\delta_\varepsilon \mathbf{\Psi}^\beta = \varepsilon^m Q_m \mathbf{\Psi}^\beta$ with Q_m given in (6) and similarly for $\mathbf{\Psi}_{\dot\beta}$.

Notice that ρ_1, $\bar\rho_1$, $\bar\rho_2$, ρ_2 and ρ_3, $\bar\rho_3$ are not irreducible representations of $\mathfrak{sl}(2,\mathbb{C}) \cong \mathfrak{so}(1,3)$, we therefore define

$$\begin{aligned} &\rho_1 = \varphi\, I_2 + \frac{1}{2} B_{mn}\, \sigma^{nm}, \qquad \bar\rho_1 = \varphi'\, \bar I_2 + \frac{1}{2} B'_{mn} \bar\sigma^{nm}, \qquad \bar\rho_2 = A^m\, \bar\sigma_m, \qquad \rho_2 = A'^m\, \sigma_m, \\ &\rho_3 = \tilde\varphi\, I_2 + \frac{1}{2} \tilde B_{mn}\, \sigma^{nm}, \qquad \bar\rho_3 = \tilde\varphi'\, \bar I_2 + \frac{1}{2} \tilde B'{}_{mn}\, \bar\sigma^{nm} \end{aligned} \tag{9}$$

with I_2 and $\bar I_2$ the two by two identity matrices, σ_{mn} and $\bar\sigma_{mn}$ the Lorentz generators for the two spin representations, A^m and A'^m two vectors, φ, $\tilde\varphi$ and φ', $\tilde\varphi'$ four scalars, B_{mn}, $\tilde B_{mn}$ two self-dual two-forms and $B'{}_{mn}$, $\tilde B'{}_{mn}$ two anti-self-dual two-forms. Then one can show that the transformations read [20]

$$\begin{aligned} &\delta_\varepsilon \varphi = \Lambda^{1/3} \varepsilon^m A_m, \qquad \delta_\varepsilon \varphi' = \Lambda^{1/3} \varepsilon^m A'_m, \\ &\delta_\varepsilon B_{mn} = -\Lambda^{1/3} \left(\varepsilon_m A_n - \varepsilon_n A_m\right) + \Lambda^{1/3} i \varepsilon_{mnpq} \varepsilon^p A^q, \\ &\delta_\varepsilon B'_{mn} = -\Lambda^{1/3} \left(\varepsilon_m A'_n - \varepsilon_n A'_m\right) - \Lambda^{1/3} i \varepsilon_{mnpq} \varepsilon^p A'^q, \\ &\delta_\varepsilon A_m = \Lambda^{1/3} \left(\varepsilon_m \tilde\varphi + \varepsilon^n \tilde B_{mn}\right), \qquad \delta_\varepsilon A'_m = \Lambda^{1/3} \left(\varepsilon_m \tilde\varphi' + \varepsilon^n \tilde B'_{mn}\right), \\ &\delta_\varepsilon \tilde\varphi = \Lambda^{-2/3} \varepsilon^m P_m \varphi, \qquad \delta_\varepsilon \tilde\varphi' = \Lambda^{-2/3} \varepsilon^m P_m \varphi', \\ &\delta_\varepsilon \tilde B_{mn} = \Lambda^{-2/3} \varepsilon^p P_p B_{mn}, \qquad \delta_\varepsilon \tilde B'_{mn} = \Lambda^{-2/3} \varepsilon^p P_p B'_{mn}. \end{aligned} \tag{10}$$

The second bosonic multiplet being CPT conjugate to the first one, we have $\left(\bar\rho_1{}^{\dot\alpha}{}_{\dot\beta}\right)^\star = \rho_1{}^\alpha{}_\beta$, $\left(\rho_{2\alpha\dot\beta}\right)^\star = \bar\rho_{2\dot\alpha\beta}$ and $\left(\bar\rho_3{}^{\dot\alpha}{}_{\dot\beta}\right)^\star = \rho_3{}^\alpha{}_\beta$. [$B^\star$, the complex conjugate of B, is not to be confused with ${}^\star B$, the dual of B, see after.] This means, paying attention to the position of the indices, that we have

$$\varphi'^\star = -\varphi, \qquad \tilde\varphi'^\star = -\tilde\varphi, \qquad B'^\star_{mn} = -B_{mn}, \qquad \tilde B'^\star_{mn} = -\tilde B_{mn}, \qquad A'^\star_m = A_m. \tag{11}$$

These relations are compatible with the transformations laws given in (10) since ${\varepsilon_n}^\star = -\varepsilon_n$ and $P_n = -i \frac{\partial}{\partial x^n}$.

4 Invariant action

To construct a real invariant action involving the bosonic multiplets (9), we introduce the real fields

$$
\begin{aligned}
&A_- = i\frac{A-A'}{\sqrt{2}}, \qquad A_+ = \frac{A+A'}{\sqrt{2}},\\
&B_- = \frac{B-B'}{\sqrt{2}}, \qquad B_+ = i\frac{B+B'}{\sqrt{2}}, \qquad \tilde{B}_- = \frac{\tilde{B}-\tilde{B}'}{\sqrt{2}}, \qquad \tilde{B}_+ = i\frac{\tilde{B}+\tilde{B}'}{\sqrt{2}},\\
&\varphi_- = \frac{\varphi-\varphi'}{\sqrt{2}}, \qquad \varphi_+ = i\frac{\varphi+\varphi'}{\sqrt{2}}, \qquad \tilde{\varphi}_- = \frac{\tilde{\varphi}-\tilde{\varphi}'}{\sqrt{2}}, \qquad \tilde{\varphi}_+ = i\frac{\tilde{\varphi}+\tilde{\varphi}'}{\sqrt{2}}.
\end{aligned}
\tag{12}
$$

These new fields form now one (reducible) multiplet of 3SUSY, with ${}^\star B_- = B_+$ (${}^\star B_-$ is the dual of B_- [20]). The corresponding two- and three-form field strengths read

$$
\begin{aligned}
&F_{\pm mn} = \partial_m A_{\pm n} - \partial_n A_{\pm m},\\
&H_{\pm mnp} = \partial_m B_{\pm np} + \partial_n B_{\pm pm} + \partial_p B_{\pm mn}.
\end{aligned}
\tag{13}
$$

They are invariant under the gauge transformations

$$
\begin{aligned}
&\varphi_\pm \to \varphi_\pm,\\
&A_{\pm m} \to A_{\pm m} + \partial_m \chi_\pm,\\
&B_{\pm mn} \to B_{\pm mn} + (\partial_m \chi_{\pm\, n} - \partial_n \chi_{\pm\, m}),
\end{aligned}
\tag{14}
$$

where $\chi_\pm$ ($\chi^m_\pm$) are arbitrary scalar (vector) functions (χ^m_- and χ^m_+ can still be related in order to preserve the duality relations between B_- and B_+)[2].

In a similar way we introduce the field strength $\tilde{H}_{-mnp}$, $\tilde{H}_{+mnp}$, as well as the dual fields ${}^\star H_{-m}$, ${}^\star H_{+m}$, ${}^\star \tilde{H}_{-m}$, ${}^\star \tilde{H}_{+m}$ (where ${}^\star H_m \equiv \frac{1}{6}\varepsilon_{mnpq}H^{npq}$. For instance ${}^\star \tilde{H}_{-m} = i\partial^n B_{+mn}$). We consider now the following local gauge invariant and zero graded Lagrangian,

$$
\begin{aligned}
\mathcal{L} = {}& \partial_m\varphi_-\partial^m\tilde{\varphi}_- - \partial_m\varphi_+\partial^m\tilde{\varphi}_+\\
&- \frac{1}{4}F_{-mn}F_-{}^{mn} + \frac{1}{4}F_{+mn}F_+{}^{mn} - \frac{1}{2}\left(\partial_m A_-{}^m\right)^2 + \frac{1}{2}\left(\partial_m A_+{}^m\right)^2\\
&- \frac{1}{12}H_{-mnp}\tilde{H}_-{}^{mnp} + \frac{1}{12}H_{+mnp}\tilde{H}_+{}^{mnp} + \frac{1}{2}{}^\star H_{-m}{}^\star\tilde{H}_-{}^m - \frac{1}{2}{}^\star H_{+m}{}^\star\tilde{H}_+{}^m.
\end{aligned}
\tag{15}
$$

By means of (12), a direct calculation shows that (15) is invariant under the transformations (10), up to a surface term. It is interesting to notice that the 3SUSY invariance is compatible with gauge symmetries if the latter are gauged fixed. A usual 't Hooft Feynman gauge fixing term $(-\frac{1}{2}\left(\partial_m A_-{}^m\right)^2 + \frac{1}{2}\left(\partial_m A_+{}^m\right)^2)$ is required for the vector fields. For the two forms, due to the relation ${}^\star B_- = B_+$ also some gauge fixing terms *à la* 't Hooft Feynman are present. Developing all terms in (15) the Lagrangian can be rewritten *à la* "Fermi-like"

$$
\begin{aligned}
\mathcal{L} = {}& \partial_m\varphi_-\partial^m\tilde{\varphi}_- - \frac{1}{2}\partial_m A_{-n}\partial^m A_-{}^n + \frac{1}{4}\partial_m B_{-np}\partial^m\tilde{B}_{-np}\\
&- \partial_m\varphi_+\partial^m\tilde{\varphi}_+ + \frac{1}{2}\partial_m A_{+n}\partial^m A_+{}^n - \frac{1}{4}\partial_m B_{+np}\partial^m\tilde{B}_{+np}
\end{aligned}
$$

(a similar Lagrangian appears in the action-at-a-distance formalism for vector and two-forms – see *e.g.* [23]).

[2]Note that the gauge transformations (14) correspond naturally to the zero-, one- and two-form character of the components of the 3SUSY gauge multiplet.

One should note, though, the relative minus signs in front of the kinetic terms of the vector fields in (15) which endanger *a priori* the boundedness from below of the density energy of the "electromagnetic" fields. This difficulty does not have a clear physical interpretation as long as interaction terms have not been included, and necessitates a more careful study of the field manifold associated to the density energy.

5 Noether currents

The 3SUSY algebra we have studied has one main difference from the usual Lie (super)algebra: it does not close through quadratic, but rather cubic, relations. Moreover, it might be possible that some usual results of Lie (super)algebra do not apply straightforwardly. One example is the Noether currents and their associated algebra. This interesting point was studied in [20].

In this section we would like, however, to construct explicitly the Noether current. Using (15) and (10) we obtain

$$\begin{aligned} J_{mn} = &-i\Lambda^{1/3}(A_{-n}\partial_m\tilde{\varphi}_- - \partial_m A_{-n}\tilde{\varphi}_-) - i\Lambda^{1/3}(A_{+n}\partial_m\tilde{\varphi}_+ - \partial_m A_{+n}\tilde{\varphi}_+) \\ &+ i\Lambda^{1/3}(\tilde{B}_{-rn}\partial_m A^r_- - \tilde{B}_{-rn}\partial_m A^r_-) + i\Lambda^{1/3}(\tilde{B}_{+rn}\partial_m A^r_+ - \tilde{B}_{+rn}\partial_m A^r_+) \\ &- i\Lambda^{-2/3}(\partial_m\varphi_-\partial_n\varphi_- - \partial_m\varphi_+\partial_n\varphi_+) - \frac{i}{4}\Lambda^{-2/3}(\partial_m B^{rs}_-\partial_n B_{-rs} - \partial_m B^{rs}_+\partial_n B_{+rs}), \end{aligned} \tag{16}$$

which is, due to the equations of motion, conserved $\partial_m J^{mn} = 0$ (up to a surface term). Then, the conserved charges are obtained as usual $\hat{Q}_m = \int d^3x J_{0m}$. Introducing the conjugate momentum Π of the fields Ψ (where Ψ is one of the fields of Section 4): $\Pi = \frac{\delta\mathcal{L}}{\delta\partial_0\Psi}$ after the usual quantization (equal-time commutation relations) one easily obtains

$$\delta_\varepsilon\Psi = \left[\varepsilon_n\hat{Q}^n, \Psi\right] \qquad \left(\delta_{Q_m}\Psi = \left[\hat{Q}^m, \Psi\right]\right). \tag{17}$$

In particular, this means that the algebra (3) is realized through

$$\begin{aligned} (\delta_{Q_m}.\delta_{Q_n}.\delta_{Q_r} + \text{perm})\,\Psi &= \left[\hat{Q}_m, \left[\hat{Q}_n, \left[\hat{Q}_r, \Psi\right]\right]\right] + \text{perm} \\ &= \eta_{mn}\left[\hat{P}_r, \Psi\right] + \eta_{mr}\left[\hat{P}_n, \Psi\right] + \eta_{rn}\left[\hat{P}_m, \Psi\right] = (\eta_{mn}\delta_{P_r} + \eta_{mr}\delta_{P_n} + \eta_{rn}\delta_{P_m})\,\Psi \end{aligned} \tag{18}$$

with $\hat{P}$ the generators of the Poincaré translations. Indeed, starting with the abstract algebra (3), we can represent it by some matrices as in Section 3 (see *e.g.* (4)). In this case the product of two transformations will be given by $\delta_n\delta_m\Psi = Q_nQ_m\Psi$ and the algebra will be realized as in (7). But, we can also represent (3) with commutators (17) acting on some Hilbert space, thus the product of two transformations will be given by $\delta_n\delta_m\Psi = \left[\hat{Q}_n, \left[\hat{Q}_m, \Psi\right]\right]$ leading to the realization (18) of the algebra (3). For a more general discussion one can see [20].

6 Conclusion

In this paper we have studied some four-dimensional realizations of 3SUSY, a non-trivial extension of the Poincaré algebra different from supersymmetry. Representation theory was explicitly constructed. Then, an invariant Lagrangian involving bosonic fields was given (some Lagrangian involving fermionic fields was also considered in [20]). The next step will be to construct an interacting theory.

Referring to the supermultiplet of $N = 1$ supergravity(SUGRA) the linearization of $N = 1$ SGM action describing the nonlinear supersymmetric (NL SUSY) gravitational interaction of superon (Nambu–Goldstone (N-G) fermion) is attempted. The field contents of on-shell SUGRA supermultiplet are realized as the composites, though they have new SUSY transformations which closes on super-Poincaré (SP) algebra. Particular attentions are paid to the local Lorentz invariance.

1 Introduction

Extending the geometrical arguments of Einstein general relativity theory (EGRT) on Riemann space-time to new space-time where the coset space coordinates of $\frac{\text{superGL(4,R)}}{\text{GL(4,R)}}$ turning to the N-G fermion degrees of freedom (d.o.f.) are attached at every Riemann space-time point, we have proposed a new Einstein–Hilbert (E-H) type action [1]. The new E-H type action describes the NLSUSY [2] invariant gravitational interaction of N-G fermion *superon* in Riemann space-time.

In this paper we would like to discuss the linearization of the new E-H type action ($N = 1$ SGM action) to obtain the equivalent linear (L) SUSY [3] theory in the low energy, which is renormalizable. Considering a phenomenological potential of SGM, though qualitative and group theoretical, discussed in [4] based upon the composite picture of L SUSY representation and the recent interest in NLSUSY in superstring (membrane) world, the linearization of NLSUSY in curved space-time may be of some general interest.

The linearization of SGM is physically interesting in general, even if the consequent theory were a existing SUGRA-like, for the equivalence among them gives a new insight into the fundamental structure of nature. For the self-contained arguments we review the SGM action briefly. ($N = 1$) SGM action is given by [1];

$$L_{\text{SGM}} = -\frac{c^3}{16\pi G}|w|(\Omega + \Lambda), \tag{1}$$

$$|w| = \det w^a{}_\mu = \det(e^a{}_\mu + t^a{}_\mu), \qquad t^a{}_\mu = \frac{i}{2}\kappa^4(\bar{\psi}\gamma^a\partial_\mu\psi - \partial_\mu\bar{\psi}\gamma^a\psi), \tag{2}$$

where $e^a{}_\mu$ is the vierbein of EGRT, ψ is N-G fermion (superon), $\kappa^4 = \left(\frac{c^3\Lambda}{16\pi G}\right)^{-1}$ is the fundamental volume of four-dimensional space-time of Volkov–Akulov (V-A) model [2], and Λ is the *small* cosmological constant related to the strength of the superon-vacuum coupling constant. Ω is a new scalar curvature analogous to the Ricci scalar curvature R of EGRT, whose explicit expression is obtained by just replacing $e^a{}_\mu(x)$ by $w^a{}_\mu(x)$ in Ricci scalar R. These results can be understood intuitively by observing that $w^a{}_\mu(x) = e^a{}_\mu(x) + t^a{}_\mu(x)$ defined by $\omega^a = w^a{}_\mu dx^\mu$, where ω^a is the NL SUSY invariant differential one-form of V-A [2], is invertible,

and $s^{\mu\nu}(x) \equiv w_a{}^{\mu}(x)w^{a\nu}(x)$ are a unified vierbein and a unified metric tensor in SGM space-time [1,5]. The SGM action (1) is invariant at least under the following symmetry [6]; ordinary GL(4,R), the following new NLSUSY transformation:

$$\delta^{NL}\psi(x) = \frac{1}{\kappa^2}\zeta + i\kappa^2(\bar{\zeta}\gamma^{\rho}\psi(x))\partial_{\rho}\psi(x), \qquad \delta^{NL}e^{a}{}_{\mu}(x) = i\kappa^2(\bar{\zeta}\gamma^{\rho}\psi(x))\partial_{[\rho}e^{a}{}_{\mu]}(x), \tag{3}$$

where ζ is a constant spinor and $\partial_{[\rho}e^{a}{}_{\mu]}(x) = \partial_{\rho}e^{a}{}_{\mu} - \partial_{\mu}e^{a}{}_{\rho}$, the following GL(4,R) transformations due to (3):

$$\delta_{\zeta}w^{a}{}_{\mu} = \xi^{\nu}\partial_{\nu}w^{a}{}_{\mu} + \partial_{\mu}\xi^{\nu}w^{a}{}_{\nu}, \qquad \delta_{\zeta}s_{\mu\nu} = \xi^{\kappa}\partial_{\kappa}s_{\mu\nu} + \partial_{\mu}\xi^{\kappa}s_{\kappa\nu} + \partial_{\nu}\xi^{\kappa}s_{\mu\kappa}, \tag{4}$$

where $\xi^{\rho} = i\kappa^2\bar{\zeta}\gamma^{\rho}\psi(x)$ and $s_{\mu\nu} = w^{a}{}_{\mu}w_{a\nu}$, and the following local Lorentz transformation on $w^{a}{}_{\mu}$:

$$\delta_L w^{a}{}_{\mu} = \epsilon^{a}{}_{b}w^{b}{}_{\mu} \tag{5}$$

with the local parameter $\epsilon_{ab} = (1/2)\epsilon_{[ab]}(x)$ or equivalently on ψ and $e^{a}{}_{\mu}$

$$\delta_L\psi(x) = -\frac{i}{2}\epsilon_{ab}\sigma^{ab}\psi, \qquad \delta_L e^{a}{}_{\mu}(x) = \epsilon^{a}{}_{b}e^{b}{}_{\mu} + \frac{\kappa^4}{4}\varepsilon^{abcd}\bar{\psi}\gamma_5\gamma_d\psi(\partial_{\mu}\epsilon_{bc}). \tag{6}$$

The local Lorentz transformation forms a closed algebra, for example, on $e^{a}{}_{\mu}(x)$

$$[\delta_{L_1}, \delta_{L_2}]e^{a}{}_{\mu} = \beta^{a}{}_{b}e^{b}{}_{\mu} + \frac{\kappa^4}{4}\varepsilon^{abcd}\bar{\psi}\gamma_5\gamma_d\psi(\partial_{\mu}\beta_{bc}), \tag{7}$$

where $\beta_{ab} = -\beta_{ba}$ is defined by $\beta_{ab} = \epsilon_{2ac}\epsilon_1{}^{c}{}_{b} - \epsilon_{2bc}\epsilon_1{}^{c}{}_{a}$. The commutators of two new NLSUSY transformations (3) on $\psi(x)$ and $e^{a}{}_{\mu}(x)$ are GL(4,R), i.e. new NLSUSY (3) is the square-root of GL(4,R):

$$[\delta_{\zeta_1}, \delta_{\zeta_2}]\psi = \Xi^{\mu}\partial_{\mu}\psi, \qquad [\delta_{\zeta_1}, \delta_{\zeta_2}]e^{a}{}_{\mu} = \Xi^{\rho}\partial_{\rho}e^{a}{}_{\mu} + e^{a}{}_{\rho}\partial_{\mu}\Xi^{\rho}, \tag{8}$$

where $\Xi^{\mu} = 2i(\bar{\zeta}_2\gamma^{\mu}\zeta_1) - \xi_1^{\rho}\xi_2^{\sigma}e_a{}^{\mu}(\partial_{[\rho}e^{a}{}_{\sigma]})$. They show the closure of the algebra. SGM action (1) is invariant at least under [6]

$$[\text{global NLSUSY}] \otimes [\text{local GL}(4,\text{R})] \otimes [\text{local Lorentz}], \tag{9}$$

which is isomorphic to SP whose single irreducible representation gives the group theoretical description of SGM [4].

2 Linearization of SGM

Here we just mention that the SGM action of equation (1) is a nontrivial generalization of E-H action. Interestingly, the following local spinor translation with a local parameter $\epsilon(x)$, $\delta\psi = \epsilon$, $\delta e^{a}{}_{\mu} = -i\kappa^4(\bar{\epsilon}\gamma^{a}\partial_{\mu}\psi + \bar{\psi}\gamma^{a}\partial_{\mu}\epsilon)$, gives $\delta w^{a}{}_{\mu} = 0 = \delta w_a{}^{\mu}$. However, this local spinor transformation cannot transform away the d.o.f. of ψ. Indeed, ψ seems to be transformed away if we choose $\delta\psi = \epsilon = -\psi$, but it is restored precisely in the unified vierbein $w^{a}{}_{\mu}$ by simultaneously transforming $e^{a}{}_{\mu}$, i.e., $w(e,\psi) = w(e+\delta e, \psi+\delta\psi) = w(e+t, 0)$ as indicated by $\delta w^{a}{}_{\mu} = 0$. And also the above local spinor transformation is a fake gauge transformation in a sense that, in contrast with the local Lorentz transformation on the coordinates in the vierbein formalism of EGRT, it cannot eliminate the d.o.f. of ψ since the unified vierbein $w^{a}{}_{\mu} = e^{a}{}_{\mu} + t^{a}{}_{\mu}$ is the only gauge field on SGM space-time and contains only integer spin. This confusive situation comes from the new geometrical formulation of SGM on unfamiliar SGM space-time, where

besides the Minkowski coordinates x^a, ψ is a Grassmann coordinate (i.e. the fundamental d.o.f.) defining the tangential space-time with $\mathrm{SO}(3,1) \times \mathrm{SL}(2,\mathrm{C})$ d.o.f. inspired by NLSUSY. The local spinor transformation ($\delta\psi = \epsilon(x)$) is just a coordinate transformation (redefinition) on SGM space-time. This situation can be understood easily by observing that the unified vierbein $w^a{}_\mu = e^a{}_\mu + t^a{}_\mu$ is defined by $\omega^a = dx^a + i\kappa^4\bar{\psi}\gamma^a d\psi = w^a{}_\mu dx^\mu$, where ω^a is the NLSUSY invariant differential one-form of V-A [2] and (x^a, ψ) are coordinates specifying the (SGM) flat space-time inspired by NLSUSY.

From these geometrical viewpoints (in SGM space-time) we can understand that ψ is a coordinate and would not be transformed away and the initial SGM space-time is preserved. Eliminating ψ by some arguments regarding the above local spinor translation as a gauge transformation leads to a different theory (ordinary E-H action) with a different vacuum (Minkowski flat space-time), which is another from SGM scenario assuming that the SGM space-time is an ultimate physical entity.

The linearization of such a highly nonlinear theory is interesting and inevitable for obtaining of a renormalizable field theory which is equivalent and describes the observed low energy physics.

The flat space linearization of $N = 1$ V-A model has been carried out, and it was proved that $N = 1$ V-A model is equivalent to $N = 1$ scalar supermultiplet [7] or $N = 1$ axial vector gauge supermultiplet of linear SUSY [8]. As a flat space exercise for the extended SGM linearization, we have carried out the linearization of $N = 2$ V-A model and have shown that it is equivalent to the spontaneously broken $N = 2$ linear SUSY *vector* $J^P = 1^-$ gauge supermultiplet model with SU(2) structure [9]. Interestingly, SU(2) algebraic gauge structure of the electroweak standard model (SM) may be explained for the first time provided that the electroweak gauge bosons are the composite fields of this (SGM) type in the low energy.

In these work the linearization is carried out by using the superfield formalism and/or by the heuristic and intuitive arguments on the relations between the component fields of L SUSY and NLSUSY. In either case it is crucial to discover the SUSY invariant relations, which connect the supermultiplets of L and NL theories and reproduce the SUSY transformations.

In above-mentioned cases of the global SUSY in flat space-time the SUSY invariant relations are obtained straightforwardly, for L and NL supermultiplets are well understood and the algebraic structures are the same SP.

The situation is rather different in SGM, for (i) the supermultiplet structure of the linearized theory of SGM is unknown except if it is expected to be a broken SUSY SUGRA-like theory containing graviton and a (massive) spin 3/2 field as dynamical d.o.f. and (ii) the algebraic structure (9) is changed into SP.

Therefore, by the heuristic arguments and referring to SUGRA we discuss for the moment the linearization of $N = 1$ SGM.

At first, we assume faithfully the SGM scenario that:

(i) the linearized theory should contain the spontaneously broken *global* (at least) SUSY;

(ii) graviton is an elementary field (not composite of superons corresponding to the vacuum of the Clifford algebra) in both L and NL theories;

(iii) the NLSUSY supermultiplet of SGM ($e^a{}_\mu(x)$, $\psi(x)$) should be connected to the composite supermultiplet ($\tilde{e}^a{}_\mu(e(x), \psi(x))$, $\tilde{\lambda}_\mu(e(x), \psi(x))$) for elementary graviton field and a composite (massive) spin 3/2 field of the SUGRA-like linearized theory.

From these assumptions and following the arguments used in the flat space cases we require that the SUGRA gauge transformation [10] with the global spinor parameter ζ should hold for the supermultiplet ($\tilde{e}^a{}_\mu(e, \psi)$, $\tilde{\lambda}_\mu(e, \psi)$) of the (SUGRA-like) linearized theory, i.e.,

$$\delta\tilde{e}^a{}_\mu(e, \psi) = i\kappa\bar{\zeta}\gamma^a\tilde{\lambda}_\mu(e, \psi), \tag{10}$$

$$\delta\tilde{\lambda}_\mu(e,\psi) = \frac{2}{\kappa}D_\mu\zeta = -\frac{i}{\kappa}\tilde{\omega}(e,\psi)_\mu{}^{ab}\sigma_{ab}\zeta, \tag{11}$$

where $\sigma^{ab} = \frac{i}{4}[\gamma^a,\gamma^b]$, $D_\mu = \partial_\mu - \frac{i}{2}\omega_\mu{}^{ab}(e,\psi)\sigma_{ab}$, ζ is a global spinor parameter and the variations in the left-hand side are induced by NLSUSY (3).

We put the following SUSY invariant relations, which connect $e^a{}_\mu$ to $\tilde{e}^a{}_\mu(e,\psi)$:

$$\tilde{e}^a{}_\mu(e,\psi) = e^a{}_\mu(x). \tag{12}$$

This relation (12) is the assumption (ii) and holds simply from the metric conditions. Consequently, the following covariant relation is obtained by substituting (12) into (10) and computing the variations under (3) [11]:

$$\tilde{\lambda}_\mu(e,\psi) = \kappa\gamma_a\gamma^\rho\psi(x)\partial_{[\rho}e^a{}_{\mu]}. \tag{13}$$

(As discussed later, these may be considered as the leading order of the expansions in κ of SUSY invariant relations. The expansions terminate with $(\psi)^4$. Now we see LSUSY transformation induced by (3) on the (composite) supermultiplet $(\tilde{e}^a{}_\mu(e,\psi),\ \tilde{\lambda}_\mu(e,\psi).)$

The LSUSY transformation on $\tilde{e}^a{}_\mu$ becomes as follows. The left-hand side of (10) gives

$$\delta\tilde{e}^a{}_\mu(e,\psi) = \delta^{NL}e^a{}_\mu(x) = i\kappa^2(\bar{\zeta}\gamma^\rho\psi(x))\partial_{[\rho}e^a{}_{\mu]}(x). \tag{14}$$

While substituting (13) into the right-hand side of (10) we obtain

$$i\kappa^2(\bar{\zeta}\gamma^\rho\psi(x))\partial_{[\rho}e^a{}_{\mu]}(x) + \cdots \text{ (extra terms)}. \tag{15}$$

These results show that (12) and (13) are not SUSY invariant relations and reproduce (10) with unwanted extra terms, which should be identified with the auxiliary fields. The commutator of the two LSUSY transformations induces GL(4,R) with the field dependent parameters as follows:

$$[\delta_{\zeta_1},\delta_{\zeta_2}]\tilde{e}^a{}_\mu(e,\psi) = \Xi^\rho\partial_\rho\tilde{e}^a{}_\mu(e,\psi) + \tilde{e}^a{}_\rho(e,\psi)\partial_\mu\Xi^\rho, \tag{16}$$

where $\Xi^\mu = 2i(\bar{\zeta}_2\gamma^\mu\zeta_1) - \xi_1^\rho\xi_2^\sigma e_a{}^\mu(\partial_{[\rho}e^a{}_{\sigma]})$.

On $\tilde{\lambda}_\mu(e,\psi)$, the left-hand side of (11) becomes apparently rather complicated:

$$\begin{aligned}\delta\tilde{\lambda}_\mu(e,\psi) &= \kappa\delta(\gamma_a\gamma^\rho\psi(x)\partial_{[\rho}e^a{}_{\mu]}) \\ &= \kappa\gamma_a[\delta^{NL}\gamma^\rho\psi(x)\partial_{[\rho}e^a{}_{\mu]} + \gamma^\rho\delta^{NL}\psi(x)\partial_{[\rho}e^a{}_{\mu]} + \gamma^\rho\psi(x)\partial_{[\rho}\delta^{NL}e^a{}_{\mu]}].\end{aligned} \tag{17}$$

However, the commutator of the two LSUSY transformations induces the similar GL(4,R):

$$[\delta_{\zeta_1},\delta_{\zeta_2}]\tilde{\lambda}_\mu(e,\psi) = \Xi^\rho\partial_\rho\tilde{\lambda}_\mu(e,\psi) + \tilde{\lambda}_\rho(e,\psi)\partial_\mu\Xi^\rho. \tag{18}$$

These results indicate that it is necessary to generalize (10), (11) and (13) for obtaining SUSY invariant relations and for the closure of the algebra. Furthermore, due to the complicated expression of LSUSY (17) that makes the physical and mathematical structures obscure, we can hardly guess a linearized invariant action equivalent to SGM.

Now we generalize the linearization by considering the auxiliary fields such that LSUSY transformation on the linearized fields induces SP transformation.

By comparing (11) with (17) we understand that the local Lorentz transformation plays a crucial role. As for the local Lorentz transformation on the linearized asymptotic fields corresponding to the observed particles (in the low energy), it is natural to take (irrespective of (6)) the following forms

$$\delta_L\tilde{\lambda}_\mu(x) = -\frac{i}{2}\epsilon_{ab}\sigma^{ab}\tilde{\lambda}_\mu(x), \qquad \delta_L\tilde{e^a}{}_\mu(x) = \epsilon^a{}_b\tilde{e}^b{}_\mu, \tag{19}$$

where $\epsilon_{ab} = (1/2)\epsilon_{[ab]}(x)$ is a local parameter. The relation between (6), i.e. the ultimate Lorentz invariance encoded geometrically in SGM space-time, and (19), i.e. the Lorentz invariance defined on the (composite) asymptotic field in Riemann space-time, is unclear. In SGM the local Lorentz transformations (5) and (6), i.e. the local Lorentz invariant gravitational interaction of superon, are introduced by the geometrical arguments in SGM space-time [6] following EGRT. While in SUGRA theory the local Lorentz transformation invariance (19) is realized as usual by introducing the Lorentz spin connection $\omega_\mu{}^{ab}$. And the LSUSY transformation is defined successfully by the (Lorentz) covariant derivative containing the spin connection $\tilde{\omega}_\mu{}^{ab}(e,\psi)$ as seen in (11), which causes the super-Poincaré algebra on the commutator of SUSY and is convenient for constructing the invariant action. Therefore, in the linearized (SUGRA-like) theory the local Lorentz transformation invariance is expected to be realized as usual by defining (19) and introducing the Lorentz spin connection $\omega_\mu{}^{ab}$. We investigate how the spin connection $\tilde{\omega}_\mu{}^{ab}(e,\psi)$ appears in the linearized (SUGRA-like) theory through the linearization process. This is also crucial for constructing a nontrivial (interacting) linearized action, which has manifest invariances.

We discuss the Lorentz covariance of the transformation by comparing (17) with the right-hand side of (11). The direct computation of (11) by using SUSY invariant relations (12) and (13) under (3) produces complicated redundant terms as read off from (17). The local Lorentz invariance of the linearized theory may become ambiguous and lose the manifest invariance.

For a simple restoration of the manifest local Lorentz invariance we survey the possibility that such redundant terms may be adjusted by the d.o.f. of the auxiliary fields in the linearized supermultiplet. As for the auxiliary fields it is necessary for the closure of the off-shell superalgebra to include the equal number of the fermionic and the bosonic d.o.f. in the linearized supermultiplet. As new NLSUSY is a global symmetry, $\tilde{\lambda}_\mu$ has 16 fermionic d.o.f.. Therefore at least 4 bosonic d.o.f. must be added to the off-shell SUGRA supermultiplet with 12 d.o.f. [12] and a vector field may be a simple candidate. However, counting the bosonic d.o.f. present in the redundant terms corresponding to $\tilde{\omega}_\mu{}^{ab}(e,\psi)$, we may need a bigger supermultiplet e.g. $16 + 4 \cdot 16 = 80$ d.o.f., to carry out the linearization, in which case a rank-3 tensor $\phi_{\mu\nu\rho}$ and a rank-2 tensor-spinor $\lambda_{\mu\nu}$ may be candidates for the auxiliary fields.

Now we consider the simple modification of SUGRA transformations (algebra) by adjusting the (composite) structure of the (auxiliary) fields. We take, instead of (10) and (11),

$$\delta\tilde{e}^a{}_\mu(x) = i\kappa\bar{\zeta}\gamma^a\tilde{\lambda}_\mu(x) + \bar{\zeta}\tilde{\Lambda}^a{}_\mu, \tag{20}$$

$$\delta\tilde{\lambda}_\mu(x) = \frac{2}{\kappa}D_\mu\zeta + \tilde{\Phi}_\mu\zeta = -\frac{i}{\kappa}\tilde{\omega}_\mu{}^{ab}\sigma_{ab}\zeta + \tilde{\Phi}_\mu\zeta, \tag{21}$$

where $\tilde{\Lambda}^a{}_\mu$ and $\tilde{\Phi}_\mu$ represent symbolically the auxiliary fields $80+80$ and are functionals of $e^a{}_\mu$ and ψ. We need $\tilde{\Lambda}^a{}_\mu$ term in (20) to alter (14), (16), (17) and (18) toward that of super-Poincaré algebra of SUGRA. We attempt the restoration of the manifest local Lorentz invariance order by order by adjusting $\tilde{\Lambda}^a{}_\mu$ and $\tilde{\Phi}_\mu$. In fact, the Lorentz spin connection $\omega_\mu{}^{ab}(e)$ (i.e. the leading order terms of $\tilde{\omega}_\mu{}^{ab}(e,\psi)$) of (21) is reproduced by taking the following one

$$\tilde{\Lambda}^a{}_\mu = \frac{\kappa^2}{4}[ie_b{}^\rho\partial_{[\rho}e^b{}_{\mu]}\gamma^a\psi - \partial_{[\rho}e_{|b|\sigma]}e^b{}_\mu\gamma^a\sigma^{\rho\sigma}\psi], \tag{22}$$

which holds (16). Accordingly $\tilde{\lambda}_\mu(e,\psi)$ is determined up to the first order in ψ as follows:

$$\tilde{\lambda}_\mu(e,\psi) = \frac{1}{2i\kappa}(i\kappa^2\gamma_a\gamma^\rho\psi(x)\partial_{[\rho}e^a{}_{\mu]} - \gamma_a\tilde{\Lambda}^a{}_\mu) = -\frac{i\kappa}{2}\omega_\mu{}^{ab}(e)\sigma_{ab}\psi, \tag{23}$$

which indicates the minimal Lorentz covariant gravitational interaction of superon. Substituting (23) into (21) we obtain the following new LSUSY transformation of $\tilde{\lambda}_\mu$ (after Fiertz transformations)

$$\delta\tilde{\lambda}_\mu(e,\psi) = -\frac{i\kappa}{2}\{\delta^{NL}\omega_\mu{}^{ab}(e)\sigma_{ab}\psi + \omega_\mu{}^{ab}(e)\sigma_{ab}\delta^{NL}\psi\}$$

$$= -\frac{i}{2\kappa}\omega_\mu{}^{ab}(e)\sigma_{ab}\zeta + \frac{i\kappa}{2}\{\tilde{\epsilon}^{ab}(e,\psi)\sigma_{ab}\cdot\omega_\mu{}^{cd}(e)\sigma_{cd}\psi + \cdots\}. \tag{24}$$

Remarkably, the local Lorentz transformations of $\tilde{\lambda}_\mu(e,\psi)$ (i.e. the second term) with the field dependent antisymmetric parameters $\tilde{\epsilon}^{ab}(e,\psi)$ are induced in addition to the intended ordinary global SUSY transformation. (23) are the SUSY invariant relations for $\tilde{\lambda}_\mu(e,\psi)$ in the lowest order with ψ, for the SUSY transformation of (23) gives the right hand side of (21) with the consequent auxiliary fields. Interestingly the commutator of the two LSUSY transformations on (23) induces GL(4,R):

$$[\delta_{\zeta_1},\delta_{\zeta_2}]\tilde{\lambda}_\mu(e,\psi) = \Xi^\rho\partial_\rho\tilde{\lambda}_\mu(e,\psi) + \partial_\mu\Xi^\rho\tilde{\lambda}_\rho(e,\psi), \tag{25}$$

where Ξ^ρ is the same field dependent parameter as given in (16). (16) and (25) show the closure of the algebra on SP algebra provided that the SUSY invariant relations (12) and (23) are adopted. These phenomena coincide with SGM scenario [1,4] from the algebraic point of view, i.e. they are the superon-graviton composite (eigenstates) corresponding to the linear representations of SP algebra. As for the redundant terms in (24) with $(\psi)^2$ the SUSY transformations we can recast them by considering the modified spin connection $\tilde{\omega}_\mu{}^{ab}(e,\psi)$ particularly with the contorsion terms and (the auxiliary field) $\tilde{\Phi}_\mu(e,\psi)$. In fact, we have proved that the contributions to (24) from the SUGRA-inspired contorsion terms:

$$\begin{aligned} K_{\mu ab}\sigma^{ab}\psi &= \frac{i\kappa^2}{4}(\bar{\tilde{\lambda}}_a\gamma_b\tilde{\lambda}_\mu - \bar{\tilde{\lambda}}_b\gamma_a\tilde{\lambda}_\mu + \bar{\tilde{\lambda}}_a\gamma_\mu\tilde{\lambda}_b)\sigma^{ab}\psi \\ &= \frac{i\kappa^4}{16}\{(e_a{}^\mu\bar{\psi}\sigma^{cd}\omega_{\nu cd}(e)\gamma_b\omega_{\mu fg}(e)\sigma^{fg}\psi - [a\leftrightarrow b] + \cdots\}\sigma^{ab}\psi, \end{aligned} \tag{26}$$

satisfies

$$[\delta_{\zeta_1},\delta_{\zeta_2}](K_{\mu ab}\sigma^{ab}\psi) = \Xi^\rho\partial_\rho(K_{\mu ab}\sigma^{ab}\psi) + \partial_\mu\Xi^\rho(K_{\rho ab}\sigma^{ab}\psi). \tag{27}$$

We can obtain the complete linearized (off-shell) supermultiplets of the super-Poincaré algebra by repeating the similar procedures (including the auxiliary fields $80+80$) order by order which terminates with $(\psi)^4$. The complicated procedures has been carried out successfully up to $O(\psi^2)$ [13].

Finally, we mention another way of the systematic linearization by using the superfield formalism applied to the coupled system of V-A action with SUGRA [14]. We can define on such a coupled system a local spinor gauge symmetry, which induces a super-Higgs mechanism [15] converting V-A field to the longitudinal component of massive spin 3/2 field. The consequent Lagrangian obtained may be an analogue of what we anticipated in above discussions but with the elementary spin 3/2 field.

The linearization of the new E-H type action (1) with the extra dimensions, which gives another unification framework describing the observed particles as elementary fields, is open. And the linearization of SGM action for spin 3/2 N-G fermion field [16] (with extra dimensions) may be in the same scope.

3 Discussion

Now we summarize the results as follows. Referring to SUGRA transformations we have attempted explicitly the linearization of $N=1$ SGM up to $O(\psi^2)$ in the (SUGRA-like) LSUSY transformations. The closure of the new LSUSY transformations (20) and (24) on the linearized supermultiplet, which are different from SUGRA transformations, can be proved order by order with ψ by introducing the auxiliary fields. It is interesting that the simple relation

$\lambda_\mu = e^a{}_\mu \gamma_a \psi + \cdots$, which is suggested by the flat space-time linearization, seems disfavour with the SGM linearization. As conjectured before, what LSUSY SP may be to SGM in quantum field theory, what O(4) symmetry is to the relativistic hydrogen model in quantum mechanics, which is tested by the linearization. The linearization of SGM is physically interesting in general, even if it were a existing SUGRA-like theory, for the consequent broken LSUSY theory is shown to be equivalent and gives a new insight into the fundamental structure of nature (like the relation between Landau–Ginzberg theory and BCS theory for superconductivity). The complete linearization to all orders, which can be anticipated by the systematics emerging in the present study, needs specifications of the auxiliary fields and remains to be studied. They are now in progress.

The Hamiltonian and covariant generators of κ-symmetry and extra bosonic gauge symmetries of superstring and super p-branes preserving 3/4 of the $D = 4$ $N = 1$ supersymmetry are presented.

1 Introduction

As shown in [1] exotic BPS states preserving $\frac{\mathsf{M}-1}{\mathsf{M}}$ fraction of $N = 1$ supersymmetry can be realized by static configurations of free tensionless super p-branes ($p = 1, 2, \ldots$) with the action linear in derivatives[1]. These static configurations were described by general solutions of the equations of motion of super p-branes evolving in superspace extended by tensor central charge (TCC) coordinates. Because of the $OSp(1|2\mathsf{M})$ global symmetry of the model, its static p-brane solution was formulated in terms of supertwistor previously used to formulate superparticle models [3–5] and forming a subspace of the $Sp(2\mathsf{M})$ invariant symplectic space [6, 7]. As a result, the static form of the discussed supertwistor representation of the BPS brane solution is not static in terms of the original superspace-time and TCC coordinates. It is static only modulo transformations of enhanced κ-symmetry and its accompanying local symmetries, since the supertwistor components are invariant under these gauge symmetries, as shown in [8]. In the bosonic sector the unphysical p-brane motions related to the gauge symmetries were geometrically realized as the Abelian shifts [8] of the space-time and TCC coordinates by the Lorentz bivectors (generally multivectors) generalizing vector light-like Penrose shifts of the standard space-time coordinates [9]. Being inessential on the classical level of consideration, these shifts may turn out to be essential in the quantum dynamics of strings and branes. This necessitates quantum treatment of the model [1] in the original variables that belong to the superspace extended by TCC coordinates and auxiliary spinor fields. Interest to this problem is stimulated by a conjectured relation of the tensionless strings with higher spin theories and free conformal SYM theories [10, 11, 7], as well as by the presence of higher spin states in the quantized $OSp(1|2\mathsf{M})$ invariant model of superparticle [12].

In this talk we start study of the formulated problem on the example of $D = 4$ $N = 1$ super p-brane model [1] and consider its Hamiltonian description, based on the covariant approach to the first- and second-class constraints division [13, 14], correlating with the description [15] in the fixed light-cone gauge. The covariant first-class constraints which are generators of the local symmetries of the model, as well as, its Hamiltonian are presented. Further development of the results towards the exploration of quantum dynamics and symmetries of the string/brane model is discussed.

[1] New Wess–Zumino like super p-brane models nonlinear in derivatives and preserving $\frac{\mathsf{M}-1}{\mathsf{M}}$ fraction of supersymmetry were recently proposed in [2].

2 Lagrangians for strings and branes with enhanced supersymmetry and symplectic twistor

A new simple model [1] describes tensionless strings and p-branes spreading in the symplectic superspace $\mathcal{M}^{\rm susy}_{\mathsf{M}}$. For $\mathsf{M} = 2^{[\frac{D}{2}]}$ ($D = 2, 3, 4$ mod 8) this superspace naturally associates with D-dimensional Minkowski space-time extended by the Majorana spinor θ_a ($a = 1, 2, \ldots, 2^{[\frac{D}{2}]}$) and the tensor central charge coordinates z_{ab} additively unified with the standard space-time coordinates $x_{ab} = x^m(\gamma_m C^{-1})_{ab}$ in the symmetric spin-tensor Y_{ab}. The supersymmetric and reparametrization invariant action of the model [1]

$$S_p = \frac{1}{2}\int d\tau d^p\sigma\ \rho^\mu U^a W_{\mu ab} U^b \tag{1}$$

includes the world-volume pullback

$$W_{\mu ab} = \partial_\mu Y_{ab} - 2i(\partial_\mu\theta_a\theta_b + \partial_\mu\theta_b\theta_a),$$

of the supersymmetric Cartan differential one-form $W_{ab} = W_{\mu ab}d\xi^\mu$, where $\partial_\mu \equiv \frac{\partial}{\partial\xi^\mu}$ and $\xi^\mu = (\tau, \sigma^M) \equiv (\tau, \vec{\sigma})$, ($M = 1, 2, \ldots, p$) are world-volume coordinates. The local auxiliary Majorana spinor $U^a(\tau, \sigma^M)$ parametrizes the generalized momentum $P^{ab} = \rho^\tau U^a U^b$ of the tensionless p-brane and $\rho^\mu(\tau, \sigma^M)$ is the world-volume vector density providing the reparametrization invariance of S_p. This action has $(\mathsf{M}-1)$ κ-symmetries and consequently preserves $\frac{\mathsf{M}-1}{\mathsf{M}}$ fraction of the original global supersymmetry.

By the generalized Penrose transformation of variables

$$Y_{ab}U^b = i\tilde{Y}_a + \tilde{\eta}\theta_a, \qquad \tilde{\eta} = -2i(U^a\theta_a), \tag{2}$$

where $\tilde{\eta}$ is real Goldstone fermion associated with the spontaneous breakdown of $\frac{1}{\mathsf{M}}$ supersymmetry, the differential one-form $U^aW_{ab}U^b$ is presented as

$$U^aW_{ab}U^b = i\{U^a d\tilde{Y}_a - dU^a\tilde{Y}_a + d\tilde{\eta}\tilde{\eta}\} \equiv dY^\Lambda G_{\Lambda\Sigma}Y^\Sigma. \tag{3}$$

The new object $Y^\Lambda = (iU^a, \tilde{Y}_a, \tilde{\eta})$ in (2), (3) is $OSp(1|2\mathsf{M})$ supertwistor and $G_{\Lambda\Sigma} = (-)^{\Lambda\Sigma+1}G_{\Sigma\Lambda}$ is $OSp(1|2\mathsf{M})$ invariant supersymplectic metric

$$G_{\Lambda\Sigma} = \begin{pmatrix} \omega^{(2\mathsf{M})} & 0 \\ 0 & i \end{pmatrix} = \begin{pmatrix} 0 & -\delta_a{}^b & 0 \\ \delta^a{}_b & 0 & 0 \\ 0 & 0 & i \end{pmatrix},$$

which is the supersymmetric generalization of $Sp(2\mathsf{M})$ symplectic metric $\omega^{(2\mathsf{M})}$. In view of (2) and (3), the action S_p (1) is presented in the supertwistor form

$$S_p = \frac{1}{2}\int d\tau d^p\sigma\ \rho^\mu\partial_\mu Y^\Lambda G_{\Lambda\Sigma}Y^\Sigma \tag{4}$$

that is apparently invariant under global $OSp(1|2\mathsf{M})$ symmetry. For the particular case of $D = 11$ the action (4) is invariant under $OSp(1|64)$ generalized superconformal symmetry [16].

The original action (1) is invariant under $(\mathsf{M}-1)$ κ-symmetries since the transformation parameter $\kappa_a(\tau, \vec{\sigma})$ is restricted by only one real condition

$$U^a\kappa_a = 0, \tag{5}$$

as it follows from the transformation rules of the primary variables

$$\delta_\kappa\theta_a = \kappa_a, \qquad \delta_\kappa Y_{ab} = -2i(\theta_a\kappa_b + \theta_b\kappa_a), \qquad \delta_\kappa U^a = 0. \tag{6}$$

It is easy to show [8] that all components of the supertwistor $Y^\Lambda = (iU^a, \tilde{Y}_a, \tilde{\eta})$ are invariant under κ-symmetry transformations (5), (6)

$$\delta_\kappa \tilde{Y}_a = 0, \qquad \delta_\kappa \tilde{\eta} = 0, \qquad \delta_\kappa U^a = 0,$$

so that new representation of S_p (4) includes only κ-invariant variables. Note that in 4-dimensional space-time Y^Λ contains only 9 real variables that is twice less than the number of the original variables Y_{ab}, θ_a, U^a.

3 Example of $OSp(1|8)$ string/brane. Primary constraints

$OSp(1|8)$ is the global supersymmetry of the massless fields of all spins in $D = 4$ space-time extended by TCC coordinates [6, 7]. Therefore, we study $D = 4$ example of the string/brane model (1) formulated in generalized $(4 + 6)$-dimensional space $\mathcal{M}_{4+6}$ extended by the Grassmannian Majorana bispinor θ_a. In this case the $D = 4$ $N = 1$ superalgebra

$$\{Q_a, Q_b\} = \left(\gamma^m C^{-1}\right)_{ab} P_m + i\left(\gamma^{mn} C^{-1}\right)_{ab} Z_{mn}$$

includes the TCC 2−form generator Z_{mn}, and the matrix coordinates Y_{ab} are

$$Y_{ab} = x_{ab} + z_{ab},$$

where

$$x_{ab} = x_m \left(\gamma^m C^{-1}\right)_{ab}, \qquad z_{ab} = z_{mn} \left(\gamma^{mn} C^{-1}\right)_{ab}$$

with the charge conjugation matrix C chosen to be imaginary in the Majorana representation. Here we use the same agreements about the spinor algebra as in [1]. In the Weyl basis real symmetric 4×4 matrix Y_{ab} is presented as

$$Y_a{}^b = Y_{ad} C^{db} = \begin{pmatrix} z_\alpha{}^\beta & x_{\alpha\dot{\beta}} \\ \tilde{x}^{\dot{\alpha}\beta} & \bar{z}^{\dot{\alpha}}{}_{\dot{\beta}} \end{pmatrix}, \qquad C^{ab} = \begin{pmatrix} \epsilon^{\alpha\beta} & 0 \\ 0 & \epsilon_{\dot{\alpha}\dot{\beta}} \end{pmatrix}.$$

In the $D = 4$ case the auxiliary Majorana spinor $U^a(\tau, \sigma^M)$ complemented by another auxiliary Majorana spinor $V^a(\tau, \sigma^M)$ forms a spinor basis together with the spinors $(\gamma_5 U)_a$ and $(\gamma_5 V)_a$

$$U_a = \begin{pmatrix} u_\alpha \\ \bar{u}^{\dot{\alpha}} \end{pmatrix}, \qquad V_a = \begin{pmatrix} v_\alpha \\ \bar{v}^{\dot{\alpha}} \end{pmatrix}, \qquad (U\gamma_5 V) = -2i, \qquad (UV) = 0,$$

where the γ_5-matrix is

$$\gamma_5 = \begin{pmatrix} -i\delta^\beta_\alpha & 0 \\ 0 & i\delta^{\dot{\alpha}}_{\dot{\beta}} \end{pmatrix}.$$

Respectively the linear independent Weyl spinors u^α and v^α attached to the string/brane world volume may be identified with the local Newman–Penrose dyad [9]

$$u^\alpha v_\alpha \equiv u^\alpha \varepsilon_{\alpha\beta} v^\beta = 1, \qquad u^\alpha u_\alpha = v^\alpha v_\alpha = 0.$$

In the Weyl basis the action (1) acquires the form

$$S_p = \frac{1}{2} \int d\tau d^p\sigma \ \rho^\mu \left(2u^\alpha \omega_{\mu\alpha\dot{\alpha}} \bar{u}^{\dot{\alpha}} + u^\alpha \omega_{\mu\alpha\beta} u^\beta + \bar{u}^{\dot{\alpha}} \bar{\omega}_{\mu\dot{\alpha}\dot{\beta}} \bar{u}^{\dot{\beta}}\right), \tag{7}$$

where the supersymmetric one-forms $\omega_{\mu\alpha\dot\alpha}$ and $\omega_{\mu\alpha\beta}$ are

$$\omega_{\mu\alpha\dot\alpha} = \partial_\mu x_{\alpha\dot\alpha} + 2i(\partial_\mu\theta_\alpha\bar\theta_{\dot\alpha} + \partial_\mu\bar\theta_{\dot\alpha}\theta_\alpha),$$
$$\omega_{\mu\alpha\beta} = -\partial_\mu z_{\alpha\beta} - 2i(\partial_\mu\theta_\alpha\theta_\beta + \partial_\mu\theta_\beta\theta_\alpha),$$
$$\bar\omega_{\mu\dot\alpha\dot\beta} = -\partial_\mu\bar z_{\dot\alpha\dot\beta} - 2i(\partial_\mu\bar\theta_{\dot\alpha}\bar\theta_{\dot\beta} + \partial_\mu\bar\theta_{\dot\beta}\bar\theta_{\dot\alpha}).$$

The momenta densities $\mathcal{P}^{\mathfrak{M}}(\tau,\sigma^M)$

$$\mathcal{P}^{\mathfrak{M}} = \frac{\partial L}{\partial\dot{\mathcal{Q}}_{\mathfrak{M}}} = \left(P^{\dot\alpha\alpha}, \pi^{\alpha\beta}, \bar\pi^{\dot\alpha\dot\beta}, \pi^\alpha, \bar\pi^{\dot\alpha}, P_u^\alpha, \bar P_u^{\dot\alpha}, P_v^\alpha, \bar P_v^{\dot\alpha}, P_\mu^{(\rho)}\right)$$

are canonically conjugate to the coordinates

$$\mathcal{Q}_{\mathfrak{M}} = (x_{\alpha\dot\alpha}, z_{\alpha\beta}, \bar z_{\dot\alpha\dot\beta}, u_\alpha, \bar u_{\dot\alpha}, v_\alpha, \bar v_{\dot\alpha}, \rho^\mu)$$

with respect to the Poisson brackets

$$\{\mathcal{P}^{\mathfrak{M}}(\vec\sigma), \mathcal{Q}_{\mathfrak{N}}(\vec\sigma')\}_{\text{P.B.}} = \delta^{\mathfrak{M}}_{\mathfrak{N}}\delta^p(\vec\sigma - \vec\sigma')$$

with the periodic δ-function $\delta^p(\vec\sigma - \vec\sigma')$, where $\vec\sigma = (\sigma^1, \dots, \sigma^p)$, for the case of closed string/brane studied here.

As far as S_p (7) is linear in the proper time derivatives, it is characterized by the presence of the primary constraints. These constraints may be divided into four sectors.

The bosonic Φ-sector includes the constraints $\Phi \equiv \left(\Phi^{\dot\alpha\alpha}, \Phi^{\alpha\beta}, \bar\Phi^{\dot\alpha\dot\beta}\right)$ with

$$\begin{aligned}
&\Phi^{\dot\alpha\alpha} = P^{\dot\alpha\alpha} - \rho^\tau u^\alpha\bar u^{\dot\alpha} \approx 0,\\
&\Phi^{\alpha\beta} = \pi^{\alpha\beta} + \frac{1}{2}\rho^\tau u^\alpha u^\beta \approx 0,\\
&\bar\Phi^{\dot\alpha\dot\beta} = \bar\pi^{\dot\alpha\dot\beta} + \frac{1}{2}\rho^\tau\bar u^{\dot\alpha}\bar u^{\dot\beta} \approx 0.
\end{aligned} \tag{8}$$

The constraints from the Grassmannian Ψ-sector, where $\Psi = (\Psi^\alpha, \bar\Psi^{\dot\alpha})$, are given by

$$\begin{aligned}
&\Psi^\alpha = \pi^\alpha - 2i\bar\theta_{\dot\alpha}P^{\dot\alpha\alpha} - 4i\pi^{\alpha\beta}\theta_\beta \approx 0,\\
&\bar\Psi^{\dot\alpha} = -(\Psi^\alpha)^* = \bar\pi^{\dot\alpha} - 2iP^{\dot\alpha\alpha}\theta_\alpha - 4i\bar\pi^{\dot\alpha\dot\beta}\bar\theta_{\dot\beta} \approx 0.
\end{aligned} \tag{9}$$

The dyad or (u,v)-sector is formed by the constraints

$$\begin{aligned}
&P_u^\alpha \approx 0, \qquad \bar P_u^{\dot\alpha} \approx 0, \qquad P_v^\alpha \approx 0, \qquad \bar P_v^{\dot\alpha} \approx 0,\\
&\Xi \equiv u^\alpha v_\alpha - 1 \approx 0, \qquad \bar\Xi \equiv \bar u^{\dot\alpha}\bar v_{\dot\alpha} - 1 \approx 0.
\end{aligned} \tag{10}$$

Finally, the $\rho-$sector includes the constraints

$$P_\mu^{(\rho)} \approx 0, \qquad \mu = (\tau, M), \qquad M = (1, \dots, p). \tag{11}$$

To find all local symmetries of the brane action, it is necessary to split the constraints (8)–(11) into the first- and the second-class sets. Then the first-class constraints will generate the local symmetries on the Poisson brackets in accordance with the Dirac prescription.

4 The first-class constraints

To begin with consider the first-class constraints from the Ψ-sector (9) that generate κ-symmetry transformations (6). To find their explicit form it is necessary to solve equation (5) restricting the transformation parameter $\kappa_a(\tau,\vec{\sigma})$. Taking into account its decomposition over the dyad basis

$$\kappa_\alpha = \kappa u_\alpha + \tilde{\kappa} v_\alpha, \qquad \bar{\kappa}_{\dot{\alpha}} = \bar{\kappa}\bar{u}_{\dot{\alpha}} + \bar{\tilde{\kappa}}\bar{v}_{\dot{\alpha}}$$

it follows from equation (5) that $\tilde{\kappa} = \bar{\tilde{\kappa}}$ thus $\tilde{\kappa} = \tilde{\kappa}_R$ is real. Then the 3-parametric κ-symmetry transformation laws acquire the form

$$\begin{aligned}
&\delta_\kappa\theta_\alpha = \kappa u_\alpha, \qquad \delta_\kappa\bar{\theta}_{\dot{\alpha}} = \bar{\kappa}\bar{u}_{\dot{\alpha}},\\
&\delta_\kappa x_{\alpha\dot{\alpha}} = -2i(\kappa u_\alpha\bar{\theta}_{\dot{\alpha}} + \bar{\kappa}\bar{u}_{\dot{\alpha}}\theta_\alpha), \qquad \delta_\kappa z_{\alpha\beta} = -2i\kappa(u_\alpha\theta_\beta + u_\beta\theta_\alpha);\\
&\delta_{\tilde{\kappa}_R}\theta_\alpha = \tilde{\kappa}_R v_\alpha, \qquad \delta_{\tilde{\kappa}_R}\bar{\theta}_{\dot{\alpha}} = \tilde{\kappa}_R\bar{v}_{\dot{\alpha}},\\
&\delta_{\tilde{\kappa}_R} x_{\alpha\dot{\alpha}} = -2i\tilde{\kappa}_R(v_\alpha\bar{\theta}_{\dot{\alpha}} + \bar{v}_{\dot{\alpha}}\theta_\alpha), \qquad \delta_{\tilde{\kappa}_R} z_{\alpha\beta} = -2i\tilde{\kappa}_R(v_\alpha\theta_\beta + v_\beta\theta_\alpha).
\end{aligned} \tag{12}$$

Transformations (12) are generated on the Poisson brackets by three constraints

$$\Psi^{(u)} \equiv \Psi^\alpha u_\alpha \approx 0, \qquad \bar{\Psi}^{(u)} \equiv \bar{\Psi}^{\dot{\alpha}}\bar{u}_{\dot{\alpha}} \approx 0, \qquad \Psi_R^{(v)} \equiv \Psi^\alpha v_\alpha + \bar{\Psi}^{\dot{\alpha}}\bar{v}_{\dot{\alpha}} \approx 0$$

that belong to the first-class. The Poisson brackets of these κ-symmetry generators

$$\begin{aligned}
&\{\Psi^{(u)}(\vec{\sigma}), \bar{\Psi}^{(u)}(\vec{\sigma}')\}_{\text{P.B.}} = -4i\Phi^{(u)}\delta^p(\vec{\sigma}-\vec{\sigma}') \approx 0,\\
&\{\Psi^{(u)}(\vec{\sigma}), \Psi^{(u)}(\vec{\sigma}')\}_{\text{P.B.}} = -8iT^{(u)}\delta^p(\vec{\sigma}-\vec{\sigma}') \approx 0,\\
&\{\bar{\Psi}^{(u)}(\vec{\sigma}), \bar{\Psi}^{(u)}(\vec{\sigma}')\}_{\text{P.B.}} = -8i\bar{T}^{(u)}\delta^p(\vec{\sigma}-\vec{\sigma}') \approx 0,\\
&\{\Psi_R^{(v)}(\vec{\sigma}), \Psi_R^{(v)}(\vec{\sigma}')\}_{\text{P.B.}} = -8i\tilde{T}_R^{(v)}\delta^p(\vec{\sigma}-\vec{\sigma}') \approx 0,\\
&\{\Psi_R^{(v)}(\vec{\sigma}), \Psi^{(u)}(\vec{\sigma}')\}_{\text{P.B.}} = -2i(\tilde{T}^{(+)} - i\tilde{T}^{(-)})\delta^p(\vec{\sigma}-\vec{\sigma}') \approx 0,\\
&\{\Psi_R^{(v)}(\vec{\sigma}), \bar{\Psi}^{(u)}(\vec{\sigma}')\}_{\text{P.B.}} = -2i(\tilde{T}^{(+)} + i\tilde{T}^{(-)})\delta^p(\vec{\sigma}-\vec{\sigma}') \approx 0
\end{aligned}$$

are closed by 6 bosonic first-class constraints from the Φ-sector that were chosen as follows

$$T^{(u)} \equiv u_\alpha\Phi^{\alpha\beta}u_\beta \approx 0, \qquad \bar{T}^{(u)} = (T^{(u)})^*, \tag{13}$$

$$\Phi^{(u)} \equiv u_\alpha\Phi^{\alpha\dot{\beta}}\bar{u}_{\dot{\beta}}, \tag{14}$$

$$\tilde{T}_R^{(v)} \equiv v_\alpha\Phi^{\alpha\beta}v_\beta + \bar{v}_{\dot{\alpha}}\bar{\Phi}^{\dot{\alpha}\dot{\beta}}\bar{v}_{\dot{\beta}} + \bar{v}_{\dot{\alpha}}\Phi^{\dot{\alpha}\alpha}v_\alpha \approx 0, \tag{15}$$

$$\tilde{T}^{(+)} \equiv \Phi^{\dot{\alpha}\alpha}(u_\alpha\bar{v}_{\dot{\alpha}} + v_\alpha\bar{u}_{\dot{\alpha}}) + 2\left(\Phi^{\alpha\beta}u_{\{\alpha}v_{\beta\}} + \bar{\Phi}^{\dot{\alpha}\dot{\beta}}\bar{u}_{\{\dot{\alpha}}\bar{v}_{\dot{\beta}\}}\right) \approx 0, \tag{16}$$

$$\tilde{T}^{(-)} \equiv i\left[\Phi^{\dot{\alpha}\alpha}(u_\alpha\bar{v}_{\dot{\alpha}} - v_\alpha\bar{u}_{\dot{\alpha}}) + 2\left(\Phi^{\alpha\beta}u_{\{\alpha}v_{\beta\}} - \bar{\Phi}^{\dot{\alpha}\dot{\beta}}\bar{u}_{\{\dot{\alpha}}\bar{v}_{\dot{\beta}\}}\right)\right] \approx 0. \tag{17}$$

The meaning of the constraints (13)–(17) is that they generate local shifts of space-time and TCC coordinates along the directions defined by the moving tetrade attached to super p-brane world volume [8]. Indeed, constraints (13) correspond to local shifts of TCC coordinates along the conjugate momentum

$$\delta_{T^{(u)}} z_{\alpha\beta} = \epsilon_{T^{(u)}} u_\alpha u_\beta \approx -2\frac{\epsilon_{T^{(u)}}}{\rho^\tau}\pi_{\alpha\beta}, \qquad \delta_{\bar{T}^{(u)}}\bar{z}_{\dot{\alpha}\dot{\beta}} = \bar{\epsilon}_{\bar{T}^{(u)}}\bar{u}_{\dot{\alpha}}\bar{u}_{\dot{\beta}} \approx -2\frac{\bar{\epsilon}_{\bar{T}^{(u)}}}{\rho^\tau}\bar{\pi}_{\dot{\alpha}\dot{\beta}},$$

whereas the constraint (14) generates analogous shift for ordinary space-time coordinates

$$\delta_{\Phi^{(u)}} x_{\alpha\dot{\alpha}} = \epsilon_{\Phi^{(u)}} u_\alpha\bar{u}_{\dot{\alpha}} \approx \frac{\epsilon_{\Phi^{(u)}}}{\rho^\tau}P_{\alpha\dot{\alpha}}.$$

The local symmetry generated by the constraint (15) is the shift of space-time and TCC coordinates along another light-like direction parametrized by the dyad component v_α

$$\delta_{\tilde{T}_R^{(v)}} x_{\alpha\dot{\alpha}} = \epsilon_{\tilde{T}_R^{(v)}} v_\alpha \bar{v}_{\dot{\alpha}}, \qquad \delta_{\tilde{T}_R^{(v)}} z_{\alpha\beta} = \epsilon_{\tilde{T}_R^{(v)}} v_\alpha v_\beta, \qquad \delta_{\tilde{T}_R^{(v)}} \bar{z}_{\dot{\alpha}\dot{\beta}} = \epsilon_{\tilde{T}_R^{(v)}} \bar{v}_{\dot{\alpha}} \bar{v}_{\dot{\beta}}.$$

The action (7) is invariant under this transformation due to mutual cancellation of contributions to the variation coming from space-time and TCC coordinates. Finally constraints (16), (17) correspond to local shifts of space-time coordinates along the directions transverse to the world volume

$$\delta_{\tilde{T}^{(+)}} x_{\alpha\dot{\alpha}} = \epsilon_{\tilde{T}^{(+)}} m^{(+)}_{\alpha\dot{\alpha}}, \qquad \delta_{\tilde{T}^{(-)}} x_{\alpha\dot{\alpha}} = \epsilon_{\tilde{T}^{(-)}} m^{(-)}_{\alpha\dot{\alpha}}$$

compensated by appropriate shifts of TCC coordinates

$$\delta_{\tilde{T}^{(+)}} z_{\alpha\beta} = 2\epsilon_{\tilde{T}^{(+)}} u_{\{\alpha} v_{\beta\}}, \qquad \delta_{\tilde{T}^{(+)}} \bar{z}_{\dot{\alpha}\dot{\beta}} = 2\epsilon_{\tilde{T}^{(+)}} \bar{u}_{\{\dot{\alpha}} \bar{v}_{\dot{\beta}\}};$$
$$\delta_{\tilde{T}^{(-)}} z_{\alpha\beta} = 2i\epsilon_{\tilde{T}^{(-)}} u_{\{\alpha} v_{\beta\}}, \qquad \delta_{\tilde{T}^{(-)}} \bar{z}_{\dot{\alpha}\dot{\beta}} = -2i\epsilon_{\tilde{T}^{(-)}} \bar{u}_{\{\dot{\alpha}} \bar{v}_{\dot{\beta}\}},$$

where $u_{\{\alpha} v_{\beta\}} = \frac{1}{2}(u_\alpha v_\beta + u_\beta v_\alpha)$.

In the dyad sector there present are two first-class constraints

$$P^{(u)}_v \equiv P^\alpha_v u_\alpha \approx 0, \qquad \bar{P}^{(u)}_v \equiv \bar{P}^{\dot{\alpha}}_v \bar{u}_{\dot{\alpha}} \approx 0$$

generating shifts of v_α ($\bar{v}_{\dot{\alpha}}$) dyad components along u_α ($\bar{u}_{\dot{\alpha}}$). These shifts constitute apparent local symmetry of the action (7) as S_p does not contain v_α ($\bar{v}_{\dot{\alpha}}$).

The first-class constraints of the ρ-sector are

$$P^{(\rho)}_M \approx 0, \qquad M = (1, \ldots, p).$$

They commute with all other constraints since canonically conjugate variables ρ^M do not enter the primary constraints (8)–(11). $P^{(\rho)}_M$ constraints correspond to redefinition of p space components ρ^M of the $(p+1)$-dimensional world-volume vector density $\rho^\mu(\tau, \vec{\sigma})$

$$\delta_\epsilon \rho^M = \epsilon^M(\tau, \vec{\sigma}). \tag{18}$$

The transformations (18) are new local symmetries of the action S_p due to arbitrariness in the definition of ρ^M.

The first-class constraint that includes primary ones from the different sectors is provided by the Weyl symmetry generator

$$\Delta_W \equiv (P^\alpha_u u_\alpha + \bar{P}^{\dot{\alpha}}_u \bar{u}_{\dot{\alpha}}) - (P^\alpha_v v_\alpha + \bar{P}^{\dot{\alpha}}_v \bar{v}_{\dot{\alpha}}) - 2\rho^\mu P^{(\rho)}_\mu \approx 0.$$

The local transformation generated by Δ_W is the dilation that acts only on auxiliary variables u_α, v_α and ρ^μ

$$\rho'^\mu = e^{-2\Lambda}\rho^\mu, \qquad u'_\alpha = e^\Lambda u_\alpha, \qquad v'_\alpha = e^{-\Lambda} v_\alpha,$$
$$x'_{\alpha\dot{\alpha}} = x_{\alpha\dot{\alpha}}, \; z'_{\alpha\beta} = z_{\alpha\beta}, \qquad \theta'_\alpha = \theta_\alpha. \tag{19}$$

The transformation (19) is identified with the Weyl symmetry of the p-brane action. From the string point of view, the Weyl invariants $\rho^\mu u_\alpha \bar{u}_{\dot{\alpha}}$ and $\rho^\mu u_\alpha u_\beta$ constructed from auxiliary world-volume fields are similar to conventional Weyl invariant of tensile string

$$\sqrt{-g} g^{\mu\nu} \Leftrightarrow \rho^\mu u_\alpha \bar{u}_{\dot{\alpha}},$$

but here (19) is the symmetry the tensionless super p-brane action.

Finally the set of the first-class constraints comprises p space-like reparametrization generators

$$L_M = P^{\dot\alpha\alpha}\omega_{M\alpha\dot\alpha} - \pi^{\alpha\beta}\omega_{M\alpha\beta} - \bar\pi^{\dot\alpha\dot\beta}\bar\omega_{M\dot\alpha\dot\beta} + \partial_M\theta_\alpha\Psi^\alpha + \partial_M\bar\theta_{\dot\alpha}\bar\Psi^{\dot\alpha} + (P_u^\alpha\partial_M u_\alpha + P_v^\alpha\partial_M v_\alpha) + (\bar P_u^{\dot\alpha}\partial_M\bar u_{\dot\alpha} + \bar P_v^{\dot\alpha}\partial_M\bar v_{\dot\alpha}) - \partial_M P_\nu^{(\rho)}\rho^\nu \approx 0$$

that are the secondary constraints. The remaining time-like τ-reparametrization constraint is not independent and is constructed from the constraints $T^{(u)}$ (13), $\Phi^{(u)}$ (14) for $z_{\alpha\beta}$, $x_{\alpha\dot\alpha}$ and some algebraic combinations of the other first-class constraints for the remaining generalized coordinates.

5 The Hamiltonian

Having completed the construction of the first-class constraints we present the total gauge independent Hamiltonian density of the super p-brane in the form of their linear combination

$$H_T(\tau,\vec\sigma) = \kappa_u\Psi^{(u)} + \bar\kappa_u\bar\Psi^{(u)} + \kappa_R\Psi_R^{(v)} + a_u\Phi^{(u)} + b_uT^{(u)} + \bar b_u\bar T^{(u)} + c^{(+)}\tilde T^{(+)} + c^{(-)}\tilde T^{(-)} + c_R^{(v)}\tilde T_R^{(v)} + eP_v^{(u)} + \bar e\bar P_v^{(u)} + \omega\Delta_W + f^MP_M^{(\rho)} + \tilde\rho^ML_M \approx 0,$$

where the functions κ, a, b, c, e, f, ω and $\tilde\rho$ form the set of $(9+2p)_B + 3_F$ real Lagrange multipliers. The above Hamiltonian density yields the covariant equations of motion.

6 Conclusion

The Hamiltonian of the simplest $D = 4$ $N = 1$ super p-brane model of which general solution describes the BPS state with exotic 3/4 fraction of supersymmetry was constructed. To separate the first-class constraints in the manifestly Lorentz covariant way there has been introduced additional Weyl spinor field $v_\alpha(\tau,\vec\sigma)$ forming the local Newman–Penrose dyad [9] together with $u_\alpha(\tau,\vec\sigma)$. It was shown that the model possesses 3 fermionic first-class constraints that are generators of enhanced κ-symmetry transformations and $2p+9$ bosonic first-class constraints corresponding to space-like reparametrizations (p constraints), redefinitions of p space components of the auxiliary world-volume vector density $\rho^\mu = (\rho^\tau, \rho^M)$, shifts of the dyad components v_α along u_α (2 constraints), local Weyl symmetry (1 constraint) and 6 Abelian shifts of the space-time and TCC coordinates along the directions specified by the bilinear combinations of the dyad components. The first-class constraints fix the number of physical degrees of freedom of the p-brane model to be $n_{\rm phys} = 2(4-p)_B + 1_F$ $(0 \le p \le 4)$ and encode them by the $OSp(1|8)$ supertwistor, which is invariant under $8_B + 3_F$ gauge symmetries, as was proved in [8]. So, in the supertwistor representation $8_B + 3_F$ redundant superspace-time degrees of freedom are covariantly excluded just by the variables transformation without any gauge fixing.

The results obtained here constitute a reliable basis for the covariant separation of the second-class constraints, construction of the Dirac brackets and performing the canonical quantization of super p-brane model [1]. These results are presented in the recent papers [19].

The role of the Killing–Yano tensors in the construction of the Dirac-type operators is pointed out. The general results are applied to the case of the four-dimensional Euclidean Taub–Newman–Unti–Tamburino space. Three new Dirac-type operators, equivalent to the standard Dirac operator, are constructed from the covariantly constant Killing–Yano tensors of this space. Finally the Runge–Lenz operator for the Dirac equation in this background is expressed in terms of the fourth Killing–Yano tensor that is not covariantly constant.

1 Introduction

The (skew-symmetric) Killing–Yano (K-Y) tensors that were first introduced by Yano [1] from purely mathematical reasons, are profoundly connected to the supersymmetric classical and quantum mechanics on curved manifolds where such tensors do exist [2]. The K-Y tensors play an important role in theories with spin and especially in the Dirac theory on curved space-times where they produce first order differential operators, called Dirac-type operators, which anticommute with the standard Dirac one D [3]. Another virtue of the K-Y tensors is that they enter as square roots in the structure of several second rank Stäckel–Killing tensors that generate conserved quantities in classical mechanics or conserved operators which commute with D. The construction of Carter and McLenaghan depended upon the remarkable fact that the (symmetric) Stäckel–Killing tensor $K_{\mu\nu}$ involved in the constant of motion quadratic in the four-momentum p_μ

$$Z = \frac{1}{2} K^{\mu\nu} p_\mu p_\nu \tag{1}$$

has a certain square root in terms of K-Y tensors $f_{\mu\nu}$:

$$K_{\mu\nu} = f_{\mu\lambda} f^{\lambda}_{\cdot\nu}. \tag{2}$$

The K-Y tensor here is a 2-form $f_{\mu\nu} = -f_{\nu\mu}$ which satisfies the equation

$$f_{\mu\nu;\lambda} + f_{\mu\lambda;\nu} = 0.$$

These attributes of the K-Y tensors lead to an efficient mechanism of supersymmetry, especially when the Stäckel–Killing tensor $K_{\mu\nu}$ in equation (1) is proportional to the metric tensor $g_{\mu\nu}$ and the corresponding K-Y tensors in equation (2) are covariantly constant. Then each tensor of this type f^i gives rise to a Dirac-type operator D^i representing a supercharge of the superalgebra $\{D^i, D^j\} \propto D^2 \delta_{ij}$.

The general results are applied to the case of the four-dimensional Euclidean Taub–Newman–Unti–Tamburino (Taub–NUT) space. The Euclidean Taub-NUT metric is involved in many modern studies in physics. This metric might give rise to the gravitational analog of the Yang–Mills instanton [4]. The Kaluza–Klein monopole of Gross and Perry [5] and of Sorkin [6] was

obtained by embedding the Taub–NUT gravitational instanton into five-dimensional Kaluza–Klein theory. On the other hand, in the long-distant limit, the relative motion of two monopoles is approximately described by the geodesics of this space [7].

The Euclidean Taub–NUT space which is a hyper-Kähler manifold possessing three covariantly constant K-Y tensors. By means of these covariantly constant Killing–Yano tensors it is possible to construct new Dirac-type operators [3] which anticommute with the standard Dirac operator.

We show that the representation of the whole theory can be changed using the $U(2)$ transformations among them the $SU(2)$ ones are generated just by the spin-like operators constructed using the above-mentioned three Killing–Yano tensors [8, 9]. On the basis of these results, we define the parity transformation and a discrete group with eight elements formed by the transformations that relate to each other the four Dirac operators and their parity is transformed as well. We show that this discrete group is a realization of the quaternion group which is isomorphic to the dicyclic group of order eight.

The Taub–NUT space also possesses a Killing–Yano tensor which is not covariantly constant. The corresponding non-standard operator, constructed with the general rule [3] anticommutes with the standard Dirac operator but is not equivalent to it [10]. This non-standard Dirac operator is connected to the hidden symmetries of the space allowing construction of a conserved vector operator analogous to the Runge–Lenz vector of the Kepler problem. We shall discuss the behavior of this operator under discrete transformations pointing out that the hidden symmetries are in some sense decoupled from the discrete symmetries studied here [10–15].

2 Dirac equation on a curved background

In what follows we shall consider the Dirac operator on a curved background that has the form

$$D_s = \gamma^\mu \hat{\nabla}_\mu. \tag{3}$$

In this expression the Dirac matrices γ_μ are defined in local coordinates by the anticommutation relations $\{\gamma^\mu, \gamma^\nu\} = 2g^{\mu\nu} I$ and $\hat{\nabla}_\mu$ denotes the canonical covariant derivative for spinors.

Carter and McLenaghan showed that in the theory of Dirac fermions for any isometry with Killing vector R_μ there is an appropriate operator [3]:

$$X_k = -i\left(R^\mu \hat{\nabla}_\mu - \frac{1}{4}\gamma^\mu\gamma^\nu R_{\mu;\nu}\right)$$

which commutes with the *standard* Dirac operator (3).

Moreover, each Killing–Yano tensor $f_{\mu\nu}$ produces a *non-standard* Dirac operator of the form

$$D_f = -i\gamma^\mu\left(f_\mu{}^\nu \hat{\nabla}_\nu - \frac{1}{6}\gamma^\nu\gamma^\rho f_{\mu\nu;\rho}\right)$$

which anticommutes with the standard Dirac operator D_s.

3 Dirac operators of the Taub–NUT space

Let us consider the Taub–NUT space and the chart with Cartesian coordinates x^μ ($\mu, \nu, \ldots = 1, 2, 3, 4$) having the line element

$$ds^2 = g_{\mu\nu}dx^\mu dx^\nu = \frac{1}{V}dl^2 + V(dx^4 + A_i dx^i)^2,$$

where $dl^2 = (d\vec{x})^2 = (dx^1)^2+(dx^2)^2+(dx^3)^2$ is the Euclidean three-dimensional line element and $\vec{A}$ is the gauge field of a monopole. Another chart suitable for applications is that of spherical coordinates $(r,\, \theta,\, \phi,\, \chi)$ among them the first three are the spherical coordinates commonly associated with the Cartesian space ones x^i $(i, j, \ldots = 1, 2, 3)$, while $\chi + \phi = -x^4/\mu$. The real number μ is the parameter of the theory which enters in the form of the function $1/V(r) = 1 + \mu/r$. The only non-vanishing component of the vector potential in spherical coordinates is $A_\phi = \mu(1 - \cos\theta)$. This space has the isometry group $G_s = SO(3) \otimes U(1)_4$ formed by rotations of the Cartesian space coordinates and x^4 translations. The $U(1)_4$ symmetry is important since that eliminates so called NUT singularity if x^4 has the period $4\pi\mu$.

For the theory of the Dirac operators in Cartesian charts of the Taub–NUT space, it is convenient to consider the local frames given by tetrad fields $e(x)$ and $\hat{e}(x)$ as defined in [16] while the four Dirac matrices $\gamma^{\hat{\alpha}}$ that satisfy $\{\gamma^{\hat{\alpha}},\, \gamma^{\hat{\beta}}\} = 2\delta^{\hat{\alpha}\hat{\beta}}$ have to be written in the following representation

$$\gamma^i = -i \begin{pmatrix} 0 & \sigma_i \\ -\sigma_i & 0 \end{pmatrix}, \qquad \gamma^4 = \begin{pmatrix} 0 & \mathbf{1}_2 \\ \mathbf{1}_2 & 0 \end{pmatrix}, \tag{4}$$

where all of them are self-adjoint. In addition we consider the matrix

$$\gamma^5 = \gamma^1\gamma^2\gamma^3\gamma^4 = \begin{pmatrix} \mathbf{1}_2 & 0 \\ 0 & -\mathbf{1}_2 \end{pmatrix}$$

which is denoted by γ^0 in Kaluza–Klein theory explicitly involving the time [12].

The *standard* Dirac operator of the theory without explicit mass term is defined as $D_s = \gamma^{\hat{\alpha}}\hat{\nabla}_{\hat{\alpha}}$ [12, 10] where the spin covariant derivatives with local indices $\hat{\nabla}_{\hat{\alpha}}$ depend on the momentum operators, $P_i = -i(\partial_i - A_i\partial_4)$ and $P_4 = -i\partial_4$, and spin connection [12], such that the Hamiltonian operator [12, 13]

$$H = \gamma^5 D_s = \begin{pmatrix} 0 & \alpha^* \\ \alpha & 0 \end{pmatrix}$$

can be expressed in terms of Pauli operators,

$$\alpha = \sqrt{V}\left(\vec{\sigma}\cdot\vec{P} - \frac{iP_4}{V}\right), \qquad \alpha^* = V\left(\vec{\sigma}\cdot\vec{P} + \frac{iP_4}{V}\right)\frac{1}{\sqrt{V}},$$

involving the Pauli matrices σ_i. These operators give the (scalar) Klein–Gordon operator of the Taub–NUT space [12, 13], $\Delta = -\nabla_\mu g^{\mu\nu}\nabla_\nu = \alpha^*\alpha$. We specify that here the star superscript is a mere notation that does not represent the Hermitian conjugation, because we are using a non-unitary representation of the algebra of Dirac operators. Of course, this is *equivalent* to the unitary representation where all of these operators are self-adjoint [12].

The first three Killing–Yano tensors of the Taub–NUT space [17],

$$f^i = f^i_{\hat{\alpha}\hat{\beta}}\hat{e}^{\hat{\alpha}} \wedge \hat{e}^{\hat{\beta}} = 2\hat{e}^4 \wedge \hat{e}^i + \varepsilon_{ijk}\hat{e}^j \wedge \hat{e}^k$$

are rather special since they are covariantly constant. f^i define three anticommuting complex structures of the Taub–NUT manifold, their components realizing the quaternion algebra

$$f^i f^j + f^j f^i = -2\delta_{ij}, \qquad f^i f^j - f^j f^i = -2\varepsilon_{ijk}f^k.$$

Existence of these Killing–Yano tensors is linked to the hyper-Kähler geometry of the manifold and shows directly the relation between the geometry and the $N = 4$ supersymmetric extension

of the theory [2, 18]. Moreover, we can give a *physical* interpretation of these Killing–Yano tensors defining the *spin-like* operators,

$$\Sigma_i = -\frac{i}{4} f^i_{\hat{\alpha}\hat{\beta}} \gamma^{\hat{\alpha}} \gamma^{\hat{\beta}} = \begin{pmatrix} \sigma_i & 0 \\ 0 & 0 \end{pmatrix}, \tag{5}$$

that have similar properties to those of the Pauli matrices. In the pseudo-classical description of a Dirac particle [2,18] the covariantly constant Killing–Yano tensors correspond to components of the spin which are separately conserved.

Here, since the Pauli matrices commute with the Klein–Gordon operator, the spin-like operators (5) commute with H^2. Remarkable existence of the Killing–Yano tensors allows one to construct *Dirac-type* operators [3]

$$Q_i = -i f^i_{\hat{\alpha}\hat{\beta}} \gamma^{\hat{\alpha}} \hat{\nabla}^{\hat{\beta}} = \{H, \Sigma_i\} = \begin{pmatrix} 0 & \sigma_i \alpha^* \\ \alpha \sigma_i & 0 \end{pmatrix} \tag{6}$$

that anticommute with D_s and γ^5 and commute with H [10]. Another Dirac operator can be defined using the fourth Killing–Yano tensor but this will be discussed separately in Section 6.

4 Equivalent representations

In [12] we have shown that in the massless case the operators Q_i $(i = 1, 2, 3)$ and the new supercharge $Q_0 = iD_s = i\gamma^5 H$ form the basis of a $N = 4$ superalgebra obeying the anticommutation relations

$$\{Q_A, Q_B\} = 2\delta_{AB} H^2, \qquad A, B, \ldots = 0, 1, 2, 3 \tag{7}$$

linked to the hyper-Kähler geometric structure of the Taub–NUT space. In addition, we associate to each Dirac operator Q_A its own Hamiltonian operator $\tilde{Q}_A = -i\gamma^5 Q_A$ obtaining thus another set of supercharges,

$$\tilde{Q}_0 = H, \qquad \tilde{Q}_i = i[H, \Sigma_i] \tag{8}$$

that obey the same anticommutation relations as (7). Thus we find that there are two similar superalgebras of operators with precise physical meaning. Obviously, since all of these operators must be self-adjoint we have to work only with *unitary* representations of these superalgebras, up to an equivalence.

The concrete form of these supercharges depends on the representation of the Dirac matrices which can be changed at any time with the help of a non-singular operator T such that all of the 4×4 matrix operators of the Dirac theory transform as $X \to X' = TXT^{-1}$. In this way one obtains an *equivalent* representation which preserves the commutation and the anticommutation relations. In [12] we have used such transformations for pointing out that the convenient representations where we work are equivalent to unitary one. We note that some properties of the transformations changing representations in theories with two Dirac operators and their possible new applications are discussed in [19].

For example, simple and convenient transformations of the form can be chosen:

$$U(\beta, \vec{\xi}) = \begin{pmatrix} \hat{U}(\beta, \vec{\xi}) & 0 \\ 0 & \mathbf{1}_2 \end{pmatrix},$$

where $\hat{U}(\beta, \vec{\xi}) = e^{-i\beta} \hat{U}(\vec{\xi}) \in U(2) = U(1) \otimes SU(2)$ with $\hat{U}(\vec{\xi}) \in SU(2)$. This is because among these transformations one could find those linking equivalent Dirac operators.

It is interesting to observe that the $SU(2)$ transformations are generated just by the above defined spin-like operators as

$$U(\vec{\xi}) = U(0,\vec{\xi}) = e^{-i\vec{\xi}\cdot\vec{\Sigma}/2} = \begin{pmatrix} \hat{U}(\vec{\xi}) & 0 \\ 0 & \mathbf{1}_2 \end{pmatrix}. \tag{9}$$

If we take now $\vec{\xi} = 2\varphi\,\vec{n}$ with $|\vec{n}| = 1$ and $\varphi \in [0,\pi]$, we find that

$$\hat{U}(\vec{\xi}) = e^{-i\vec{\xi}\cdot\vec{\sigma}/2} = \mathbf{1}_2\cos\varphi - i\vec{n}\cdot\vec{\sigma}\sin\varphi$$

and after a little calculation we can write the concrete action of (9) as

$$Q_0' = U(\vec{\xi})Q_0U^+(\vec{\xi}) = Q_0\cos\varphi + n_iQ_i\sin\varphi, \tag{10}$$

$$Q_i' = U(\vec{\xi})Q_iU^+(\vec{\xi}) = Q_i\cos\varphi - (n_iQ_0 + \varepsilon_{ijk}n_jQ_k)\sin\varphi. \tag{11}$$

Hereby we see that the supercharges are mixed among themselves in linear combinations involving only *real* coefficients. In addition, we observe that these transformations correspond to an irreducible representation since the supercharges transform like the real components of a Pauli spinor. In other words, the usual $SU(2)$ transformations $\psi_Q \to \psi_Q' = \hat{U}^+(\vec{\xi})\psi_Q$ of the spinor-operator

$$\psi_Q = \begin{pmatrix} Q_0 - iQ_3 \\ Q_2 - iQ_1 \end{pmatrix}$$

give just the transformations (10) and (11).

5 Discrete transformations

Let us focus now only on the transformations which transform the supercharges Q_A among themselves without affecting their form. From (10) and (11) we see that there exist particular transformations,

$$Q_k = U_kQ_0U_k^+, \qquad k = 1,2,3,$$

where the matrix $U_k = \mathrm{diag}(-i\sigma_k, \mathbf{1}_2)$ is given by $-i\sigma_k \in SU(2)$. In addition, we consider the *parity* operator $P = P^{-1} = -\gamma^5$ that changes the sign of supercharges,

$$PQ_AP = -Q_A, \qquad A = 0,1,2,3. \tag{12}$$

Then it is not hard to verify that the identity $I = \mathbf{1}_4$, P and the sets of matrices U_k and PU_k $(k = 1,2,3)$ form a discrete group of order eight, the multiplication table of which is determined by the following rules

$$\begin{aligned} &P^2 = I, \qquad PU_k = U_kP, \\ &{U_1}^2 = {U_2}^2 = {U_3}^2 = P, \\ &U_1U_2 = U_3, \qquad U_2U_1 = PU_3, \quad \ldots \quad \text{etc.} \end{aligned} \tag{13}$$

We denote this group by $\mathcal{G}_Q$ since it is a realization of the quaternion group $\mathbf{Q}$ which is isomorphic with the dicyclic group $\langle 2,2,2\rangle$ [20,21]. In the representation (4) of the γ-matrices, its operators are defined by proper unitary matrices (which satisfy $G^{-1} = G^+$ and $\det G = 1$, $\forall\, G \in \mathcal{G}_Q$) constructed using the elements $\pm\mathbf{1}_2, \pm i\sigma_1, \pm i\sigma_2, \pm i\sigma_3$ of the natural realization of $\mathbf{Q}$ as a discrete subgroup of $SU(2)$.

The group $\mathcal{G}_Q$ is interesting because it brings together the parity that produces the transformations (12) and the operators U_k giving sequences of the form

$$Q_1 = U_3^+ Q_2 U_3 = U_2 Q_3 U_2^+ = U_1 Q_0 U_1^+, \quad \dots \quad \text{etc.}$$

that leads to the conclusion that the Dirac operators and their parity transformed $\pm Q_A$ ($A = 0,1,2,3$), are equivalent among themselves. All these operators constitute the orbit $\Omega_Q = \{Q \,|\, Q = GQ_0G^+,\ \forall G \in \mathcal{G}_Q\}$ of the group $\mathcal{G}_Q$ in the algebra of the 4×4 matrix operators. A similar orbit $\tilde{\Omega}_Q$ can be constructed for the associated Hamiltonian operators $\pm\tilde{Q}_A$ defined by (8), if we start with $\tilde{Q}_0$ instead of Q_0. It is remarkable that each of these two orbits includes *only* operators representing (up to sign) supercharges obeying superalgebras of the form (7).

In the Kaluza–Klein theory with the time trivially added [12], the time dependent term of the whole massless Dirac operator commutes with all the operators of $\mathcal{G}_Q$ so as it remains unchanged when one replaces the space parts using the discrete transformations of this group. In these conditions all the Dirac operators of Ω_Q lead to equivalent Dirac equations from the physical point of view. These can be written in Hamiltonian form as $i\partial_t \psi_A^{(\pm)} = \pm\tilde{Q}_A \psi_A^{(\pm)}$ ($A = 0,1,2,3$) and produce the same energy spectrum which coincides with that of the Klein–Gordon equation as it results from the superalgebra (7) [22, 12].

The existence of this discrete symmetry among the four supercharges of the superalgebra of the Dirac and Dirac-type operators (or the corresponding Hamiltonian operators) must be understood as a consequence of the fact that the Taub-NUT space has a hyper-Kähler structure modeled on a quaternion inner-product space [23]. In other words, the Dirac theory in this space picks up the basic quaternion character of the tangent space showing it off as the discrete symmetry due to the group $\mathcal{G}_Q \sim \mathbf{Q}$, naturally related to the specific supersymmetries of this geometry.

6 Hidden symmetries and the fifth Dirac operator

In the Taub–NUT space, in addition to the above discussed covariantly constant Killing–Yano tensors, there exists a fourth Killing–Yano tensor,

$$f^Y = -\frac{x^i}{r} f^i + \frac{2x^i}{\mu V} \varepsilon_{ijk} \hat{e}^j \wedge \hat{e}^k,$$

which is not covariantly constant. The presence of f^Y is due to existence of the hidden symmetries of the Taub–NUT geometry that are encapsulated in three non-trivial Stäckel–Killing tensors. These are interpreted as the components of the so-called Runge–Lenz vector of the Taub–NUT problem and are expressed as symmetrized products of the Killing–Yano tensors f^Y and f^i ($i = 1,2,3$) [24].

As in the case of the Dirac operators (6), one can use f^Y for defining the fifth Dirac operator

$$Q_0^Y = -i\gamma^{\hat{\alpha}} \left(f^Y_{\hat{\alpha}\hat{\beta}} \hat{\nabla}^{\hat{\beta}} - \frac{1}{6} \gamma^{\hat{\beta}} \gamma^{\hat{\delta}} f^Y_{\hat{\alpha}\hat{\beta};\hat{\delta}} \right),$$

called here the *non-standard* or *hidden* Dirac operator to emphasize the connection with the hidden symmetry of the Taub–NUT problem. It is denoted by Q_0^Y instead of Q^Y as in [10] to point out its relation to the standard Dirac operator since it can be put in the form

$$Q_0^Y = i\frac{r}{\mu} \left[Q_0, \begin{pmatrix} \sigma_r & 0 \\ 0 & \sigma_r V^{-1} \end{pmatrix} \right],$$

where $\sigma_r = \vec{x} \cdot \vec{\sigma}/r$. We showed that Q_0^Y commutes with $\tilde{Q}_0 = H$ and anticommutes with Q_0 and γ^5 [10]. This operator is important because it allowed us to derive the explicit form of the Runge–Lenz operator $\vec{K}$ of the Dirac field in Taub–NUT background establishing its properties [10].

We recall that the components of the conserved total angular momentum $\vec{J}$, and the operators $R_i = F^{-1}K_i$ with $F^2 = {P_4}^2 - H^2$ are just the generators of the dynamical algebra of the Dirac theory in Taub–NUT background [13, 14].

Starting with Q_0^Y we can construct a new orbit Ω^Y of $\mathcal{G}_Q$ defining

$$Q_k^Y = U_k Q_0^Y U_k^+ = i\frac{r}{\mu}\left[Q_k, \begin{pmatrix} \sigma_k\sigma_r\sigma_k & 0 \\ 0 & \sigma_r V^{-1} \end{pmatrix}\right] \tag{14}$$

(for $k = 1, 2, 3$) and observing that $PQ_A^Y P = -Q_A^Y$, $A = 0, 1, 2, 3$.

From the explicit form (14) we deduce that, in contrast with the operators of the orbits Ω_Q and $\tilde{\Omega}_Q$, those of the orbit Ω^Y have more involved algebraic properties. We can show that calculating

$$H^2(Q_0^Y)^2 = H^4 + \frac{4}{\mu^2}H^2\left(\vec{J}^2 + \frac{1}{4}\right) + 4F^2P_4^2, \tag{15}$$

and it is worth comparing it with equation (7). The Dirac-type operators Q_A are characterized by the fact that their quantal anticommutator closes on the square of the Hamiltonian of the theory. No such expectation applies to the non-standard, hidden Dirac operators Q_A^Y which close on a combination of different conserved operators. Also from equation (15) it results that $(Q_A^Y)^2 \neq (Q_B^Y)^2$ if $A \neq B$ (because $\vec{J}^2$ does not commute with U_k). Moreover, one can show that the commutators $[Q_A^Y, Q_B^Y]$ have complicated forms that can not be expressed in terms of operators Q_A^Y. Therefore, neither the commutator nor the anticommutator of the pairs of operators of this orbit do not lead to significant algebraic results as the anticommutation relations (7) of the operators Q_A $(A = 0, 1, 2, 3)$.

7 Concluding remarks

In the study of the Dirac equation in curved spaces, it has been proved that the Killing–Yano tensors play an essential role in the construction of new Dirac-type operators. The Dirac-type operators constructed with the aid of covariantly constant Killing–Yano tensors are equivalent with the standard Dirac operator. The non-covariantly constant Killing–Yano tensors generate non-standard Dirac operators that are not equivalent to the standard Dirac operator and they are associated with the hidden symmetries of the space.

The Taub–NUT space has a special geometry where the covariantly constant Killing–Yano tensors exist by virtue of the metric being self-dual and the Dirac-type operators generated by them are equivalent to the standard one. The fourth Killing–Yano tensor f^Y that is not covariantly constant exists by virtue of the metric being of type D. The corresponding non-standard or hidden Dirac operator does not close on H as it can be seen from equation (15) and is not equivalent to the Dirac-type operators. As it was mentioned, it is associated with the hidden symmetries of the space allowing the construction of the conserved vector-operator analogous to the Runge–Lenz vector of the Kepler problem.

Let us mention that in the pseudo-classical spinning particle models in curved spaces from covariantly constant K-Y tensors $f_{\mu\nu}$ conserved quantities of the type $f_{\mu\nu}\theta^\mu\theta^\nu$ depending on the Grassmann variables $\{\theta^\mu\}$ can be constructed [24]. The Grassmann variables $\{\theta^\mu\}$ transform as a tangent space vector and describe the spin of the particle. The antisymmetric tensor $S^{\mu\nu} = -i\theta^\mu\theta^\nu$ generates the internal part of the local tangent space rotations. For example, in the spinning Euclidean Taub–NUT space such operators correspond to components of the spin that are separately conserved [18].

The construction of the new supersymmetries in the context of pseudo-classical mechanics can be carried over straightforwardly to the case of quantum mechanics by the usual replacement

of phase space coordinates by operators and Poisson–Dirac brackets by anticommutators [25]. In terms of these operators the supercharges are replaced by Dirac-type operators [26]. In both cases, the correspondence principle leads to equivalent algebraic structures making obvious the relations between these approaches [18].

Quadratic Lagrangians are obtained by adding surface terms involving the angular momentum to a free particle Lagrangian. Killing–Yano tensors corresponding to the manifold structure induced by the quadratic Lagrangians were calculated and the associated non-generic symmetries were presented.

1 Introduction

Symmetries of a Riemannian space are associated with conservation laws of geodesic motion in this space, the investigation of Killing vectors and Killing tensors are very important in classifying and understanding a space-time.

Killing tensors of rank two or higher cannot in general be interpreted as symmetries of a metric alone. But on the other hand they can be interpreted as symmetries on the phase space for single particles.

The Killing–Yano (KY) tensors of rank two or higher order [1–7] play an important role for new non-generic symmetries [8, 9] as well as the generalized KY tensors [10], which are deeply connected to generalized Runge–Lenz symmetry. Also recently, it was discovered that there is a connection between Lax tensors [11] and KY tensors of order three. KY tensors can be understood as an object generating non-generic supersymmetry, i.e. supersymmetry belonging to some specific space-times.

Within the same context of the Killing and KY tensors, the notion of geometric duality was defined and applied on Taub-NUT and Kerr–Newman space-times [12]. The direct way to construct the dual metrics is to calculate the Killing tensors [13, 14]. An alternative way is to find the KY tensor and contract two of them to find Killing tensors [15]. However, finding an explicit space-time with a physical significance admitting higher rank KY tensors is not an easy task, not only because of the complexity of the calculations, but also earlier it was found that not all metrics admit KY tensors of higher order [16].

In the last years a huge effort was devoted to analyzing of the importance of KY tensors [17–24] in several areas.

There were some attempts to find new geometries admitting KY tensors of order two or three. For example, the three- particle open Toda lattice was geometrized by a suitable canonical transformation, and it was realized as the geodesic system of a certain Riemannian geometry [25]. Adding a time-like dimension, a four-dimensional space-times admitting two Killing vector fields were found [25].

Motivated by the above results we decided to construct geometries admitting (KY) and Killing tensors by adding a surface term [26, 27] to a known free Lagrangian.

The main aim of this paper is to add, using suitable Lagrangian multipliers, the components of the angular momenta to a free Lagrangian in two or three dimensions and to study the non-generic symmetries of the induced manifolds.

2 Killing–Yano tensors and non-generic supercharges

An n^{th} rank KY tensor $f_{\nu_1\nu_2\cdots\nu_n}$, is an antisymmetric tensor fulfilling the following equations:

$$f_{\nu_1\nu_2\cdots(\nu_n;\lambda)} = 0, \tag{1}$$

where semicolon denotes the covariant derivative.

The spinning particle model was constructed to be supersymmetric [8, 28–30], therefore independent of the form of the metric there is always a conserved supercharge

$$Q_0 = \Pi_\mu \psi^\mu.$$

Here, Π_μ is the covariant momenta and ψ^μ are odd Grassmann variables. The existence of Killing–Yano tensors of valence n are related to non-generic supersymmetries described by the supercharge

$$Q_f = f_{\nu_1\nu_2\cdots\nu_r}\Pi^{\nu_1}\psi^{\nu_2}\cdots\psi^{\nu_r} \tag{2}$$

which is a superinvariant

$$\{Q_0, Q_f\} = 0.$$

The KY equation and the Jacobi identities guarantee that it is also a constant of motion

$$\{Q_f, H\} = 0 \qquad \text{with} \quad H = \frac{1}{2}g^{\mu\nu}\Pi_\mu\Pi_\nu$$

and with the appropriate definitions of the brackets.

3 Killing tensors and dual space-times

A Killing tensor of valence two is defined through the equation

$$K_{(\mu\nu;\alpha)} = 0. \tag{3}$$

Killing–Yano tensors of any valence can be considered as the square root of the Killing tensors of valence two in the sense that, their appropriate contractions yield

$$K_{\mu\nu} = g^{\alpha\beta}f_{\mu\alpha}f_{\beta\nu} \tag{4}$$

or for valence three it can be written as

$$K_{\mu\nu} = g^{\alpha\delta}g^{\beta\gamma}f_{\mu\alpha\beta}f_{\gamma\delta\nu}.$$

It has been shown in detail in reference [12] that $K^{\mu\nu}$ and $g^{\mu\nu}$ are reciprocally the contravariant components of the Killing tensors with respect to each other. If $K^{\mu\nu}$ is non-degenerate, then through the relation

$$K^{\mu\alpha}k_{\alpha\nu} = \delta^\mu{}_\nu,$$

the second rank non-degenerate tensor $k_{\mu\nu}$, can be viewed as the metric on the "dual" space. Furthermore, the notion of geometric duality extends to that of phase space. The constant of motion

$$K = \frac{1}{2}K^{\mu\nu}p_\mu p_\nu,$$

generates symmetry transformations on the phase space linear in momentum

$$\{x^\mu, K\} = K^{\mu\nu} p_\nu.$$

The Poisson brackets satisfy

$$\{H, K\} = 0,$$

where

$$H = \frac{1}{2} g^{\mu\nu} p_\mu p_\nu.$$

Thus, in the phase space there is a reciprocal model with constant of motion H and the Hamiltonian K.

4 Extended Lagrangians and their corresponding geometries

Let us assume that a given free Lagrangian $L(\dot{q}^i, q^i)$ admits a set of constants of motion denoted by L_i, $i = 1, \ldots, 3$. If we add the components of the angular momentum corresponding to L, the extended Lagrangian [31]

$$L' = L + \dot{\lambda}^i L_i, \qquad i = 1, \ldots, 3$$

can be rewritten as

$$L' = \frac{1}{2} a_{ij} \dot{q}^i \dot{q}^j.$$

Since a_{ij} is symmetric by construction, the issue is to find a way to construct induced manifolds. In other words we are looking to find whether a_{ij} is singular or not. If the matrix a_{ij} is singular, L' corresponds to a singular system [31]. Assuming that a_{ij} is a singular $n \times n$ matrix of rank $n-1$, we obtain non-singular symmetric matrices of order $(n-1) \times (n-1)$, where n will be 3, 5 and 6. The final step is to consider the obtained matrices as metrics on the extended space and to investigate their generic and non-generic symmetries.

4.1 The nonsingular case

As a starting point let us consider the following Lagrangian

$$L' = \frac{1}{2} \left(\dot{x}^2 + \dot{y}^2 \right) + \dot{\lambda_3} (x\dot{y} - y\dot{x}). \tag{5}$$

From (5) we obtain $L^{'} = \frac{1}{2} a_{ij} \dot{q}^i \dot{q}^j$, where a_{ij} is given by

$$a_{ij} = \begin{pmatrix} 1 & 0 & -y \\ 0 & 1 & x \\ -y & x & 0 \end{pmatrix}. \tag{6}$$

If a_{ij} is considered as a metric of a manifold, by direct calculations we obtain that the corresponding Killing vector [2] of (6) is given by

$$V = (y, -x, 0).$$

From (1) a KY tensor of order two is defined as

$$D_\lambda f_{\mu\nu} + D_\mu f_{\lambda\nu} = 0. \tag{7}$$

Solving (7) corresponding to (6) we obtained the following KY tensor

$$f_{12}=0, \qquad f_{23}=-Cx\sqrt{x^2+y^2}, \qquad f_{13}=Cy\sqrt{x^2+y^2}, \tag{8}$$

where C is a constant.

If a (KY) tensor exists, then a Killing tensor of order two is generated as in (4). Taking into account (4) and (8) a Killing tensor is constructed as

$$K_{ij}=\begin{pmatrix} y^2 & -xy & -y\left(y^2+x^2\right) \\ -xy & x^2 & x\left(x^2+y^2\right) \\ -y\left(y^2+x^2\right) & x\left(x^2+y^2\right) & 0 \end{pmatrix}.$$

5 The motion on a sphere and its induced geometries

It was proved in [32] that the motion on a sphere admits four constants of motion, the Hamiltonian and three components of the angular momentum. In the following using the surface term we will generate four-dimensional manifolds. In this case the Lagrangian is given by

$$\begin{aligned} L'=&\frac{1}{2}\left(1+\frac{x^2}{u}\right)\dot{x}^2+\frac{1}{2}\left(1+\frac{y^2}{u}\right)\dot{y}^2+\frac{xy}{u}\dot{x}\dot{y}-\frac{xy}{\sqrt{u}}\dot{\lambda_1}\dot{x}+\left(\frac{x^2}{\sqrt{u}}+\sqrt{u}\right)\dot{\lambda_2}\dot{x}\\ &-\left(\frac{y^2}{\sqrt{u}}+\sqrt{u}\right)\dot{\lambda_1}\dot{y}+\frac{xy}{\sqrt{u}}\dot{\lambda_2}\dot{y}+x\dot{\lambda_3}\dot{y}-y\dot{\lambda_3}\dot{x}, \end{aligned} \tag{9}$$

where $u=1-x^2-y^2$. From (9)we identify the singular matrix a_{ij} as

$$a_{ij}=\begin{pmatrix} 1+\frac{x^2}{u} & \frac{xy}{u} & -\frac{xy}{\sqrt{u}} & \frac{x^2}{\sqrt{u}}+\sqrt{u} & -y \\ \frac{xy}{u} & 1+\frac{y^2}{u} & -\frac{y^2}{\sqrt{u}}-\sqrt{u} & \frac{xy}{\sqrt{u}} & x \\ -\frac{xy}{\sqrt{u}} & -\frac{y^2}{\sqrt{u}}-\sqrt{u} & 0 & 0 & 0 \\ \frac{x^2}{\sqrt{u}}+\sqrt{u} & \frac{xy}{\sqrt{u}} & 0 & 0 & 0 \\ -y & x & 0 & 0 & 0 \end{pmatrix}. \tag{10}$$

Because (10) is a singular matrix of rank 4 we identify three symmetric minors of order four. If we treat these minors as metrics, we observe that they are not conformaly flat but their scalar curvatures are zero. The first metric is given by

$$g^{(1)}_{\mu\nu}=\begin{pmatrix} 1+\frac{x^2}{u} & \frac{xy}{u} & \sqrt{u}+\frac{x^2}{\sqrt{u}} & -y \\ \frac{xy}{u} & 1+\frac{y^2}{u} & \frac{xy}{\sqrt{u}} & x \\ \sqrt{u}+\frac{x^2}{\sqrt{u}} & \frac{xy}{\sqrt{u}} & 0 & 0 \\ -y & x & 0 & 0 \end{pmatrix}. \tag{11}$$

The Killing vectors of (11) have the following forms

$$V_1=(y,-x,0,0), \qquad V_2=\left(\sqrt{1-x^2-y^2}+\frac{x^2}{1-x^2-y^2},\frac{xy}{1-x^2-y^2},0,0\right),$$
$$V_3=\left(-\frac{xy}{1-x^2-y^2},-\sqrt{1-x^2-y^2}-\frac{y^2}{1-x^2-y^2},0,0\right).$$

The next step is to investigate its KY tensors. Solving (7) we obtain the following set of solutions:

One-solution is given by

$$f_{21} = \frac{C_1}{\sqrt{1-x^2-y^2}}, \tag{12}$$

others zero.

Two-by-two solution has the form

$$f_{31} = f_{42} = C. \tag{13}$$

Finally, three by three solution is

$$f_{21} = \frac{C_1}{\sqrt{-1+x^2+y^2}}, \qquad f_{31} = f_{42} = C, \tag{14}$$

where C and C_1 are constants.

Using (2), (12), (13) and (14) we can obtain the form of the non-generic supercharge Q_0.

From (10) two more metrics can be identified as

$$g^{(2)}_{\mu\nu} = \begin{pmatrix} 1+\frac{x^2}{u} & \frac{xy}{u} & -\frac{xy}{\sqrt{u}} & -y \\ \frac{xy}{u} & 1+\frac{y^2}{u} & -\sqrt{u}-\frac{y^2}{\sqrt{u}} & x \\ -\frac{xy}{\sqrt{u}} & -\sqrt{u}-\frac{y^2}{\sqrt{u}} & 0 & 0 \\ -y & x & 0 & 0 \end{pmatrix} \tag{15}$$

and

$$g^{(3)}_{\mu\rho} = \begin{pmatrix} 1+\frac{x^2}{u} & \frac{xy}{u} & -\frac{xy}{\sqrt{u}} & \frac{x^2}{\sqrt{u}}+\sqrt{u} \\ \frac{xy}{u} & 1+\frac{y^2}{u} & -\frac{y^2}{\sqrt{u}}-\sqrt{u} & \frac{xy}{\sqrt{u}} \\ -\frac{xy}{\sqrt{u}} & -\frac{y^2}{\sqrt{u}}-\sqrt{u} & 0 & 0 \\ \frac{x^2}{\sqrt{u}}+\sqrt{u} & \frac{xy}{\sqrt{u}} & 0 & 0 \end{pmatrix} \tag{16}$$

respectively. By direct calculations we obtained that the metrics (15) and (16) admit the same Killing vector as in (11). Solving the equation (7) corresponding to (15) and (16) we find one non-zero component of KY tensor as $f_{21} = \frac{C_1}{\sqrt{1-x^2-y^2}}$.

This talk examines Hamiltonians H that are not Hermitian but do exhibit space-time reflection ($\mathcal{PT}$) symmetry. If the ($\mathcal{PT}$) symmetry of H is not spontaneously broken, then the spectrum of H is entirely real and positive. Examples of $\mathcal{PT}$-symmetric non-Hermitian Hamiltonians are $H = p^2 + ix^3$ and $H = p^2 - x^4$. The apparent shortcoming of quantum theories arising from $\mathcal{PT}$-symmetric Hamiltonians is that the $\mathcal{PT}$ norm is not positive definite. This suggests that it may be difficult to develop a quantum theory based on such Hamiltonians. In this talk it is shown that these difficulties can be overcome by introducing a previously unnoticed underlying physical symmetry $\mathcal{C}$ of Hamiltonians having an unbroken $\mathcal{PT}$ symmetry. Using $\mathcal{C}$, it is shown how to construct an inner product whose associated norm *is* positive definite. The result is a new class of fully consistent complex quantum theories. Observables in these theories exhibit $\mathcal{CPT}$ symmetry, probabilities are positive, and the dynamics is governed by unitary time evolution.

1 Introduction

In this talk we discuss an alternative to a standard axiom of quantum mechanics; namely, that the Hamiltonian H, which incorporates the symmetries and specifies the dynamics of a quantum theory, must be Hermitian: $H = H^\dagger$. It is commonly believed that H must be Hermitian in order to ensure that the energy spectrum (the eigenvalues of H) is real and that the time evolution is unitary (probability is conserved in time). Although this axiom is sufficient to guarantee these desired properties, it is not necessary. We believe that the condition of Hermiticity is a mathematical requirement whose physical basis is obscure. We demonstrate here that there is a more physical alternative axiom, which we refer to as space-time reflection symmetry ($\mathcal{PT}$ symmetry): $H = H^{\mathcal{PT}}$. This symmetry allows for the possibility of non-Hermitian and complex Hamiltonians but still leads to a consistent theory of quantum mechanics.

We also show that because $\mathcal{PT}$ symmetry is an alternative condition to Hermiticity, it is now possible to construct infinitely many new Hamiltonians that would have been rejected in the past because they are not Hermitian. An example of such a Hamiltonian is $H = p^2 + ix^3$. It should be emphasized that we do not regard the condition of Hermiticity as wrong. Rather, the condition of $\mathcal{PT}$ symmetry offers the possibility of studying new quantum theories.

Let us recall the properties of the space reflection (parity) operator $\mathcal{P}$ and the time-reflection operator $\mathcal{T}$: $\mathcal{P}$ is *linear* and has the effect $p \to -p$ and $x \to -x$; $\mathcal{T}$ is antilinear and has the effect $p \to -p$, $x \to x$, and $i \to -i$. Note that $\mathcal{T}$ changes the sign of i because, like $\mathcal{P}$, it preserves the fundamental commutation relation of quantum mechanics, $[x, p] = i$.

It is easy to construct Hamiltonians that are not Hermitian but do possess $\mathcal{PT}$ symmetry. For example, consider the one-parameter family of Hamiltonians

$$H = p^2 + x^2(ix)^\epsilon \qquad (\epsilon \text{ real}). \tag{1}$$

While H in (1) is not symmetric under $\mathcal{P}$ or $\mathcal{T}$ separately, it is invariant under their combined operation. We say that such Hamiltonians possess space-time reflection symmetry. Other complex Hamiltonians having $\mathcal{PT}$ symmetry are $H = p^2 + x^4(ix)^\epsilon$ and $H = p^2 + x^6(ix)^\epsilon$ [1][1].

[1]These classes of Hamiltonians are all *different*. For example, the Hamiltonian obtained by continuing H in (1) along the path $\epsilon : 0 \to 8$ has a different spectrum from the Hamiltonian that is obtained by continuing

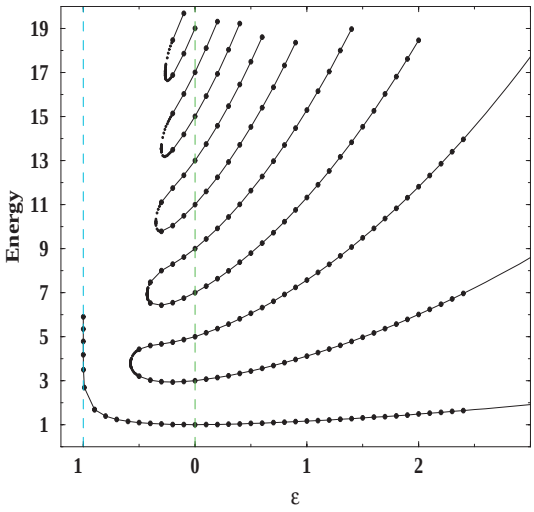

Figure 1. Energy levels of the Hamiltonian $H = p^2 + x^2(ix)^\epsilon$ as a function of the parameter ϵ. There are three regions: When $\epsilon \geq 0$, the spectrum is real and positive and the energy levels rise with increasing ϵ. The lower bound of this region, $\epsilon = 0$, corresponds to the harmonic oscillator, whose energy levels are $E_n = 2n + 1$. When $-1 < \epsilon < 0$, there is a finite number of real positive eigenvalues and an infinite number of complex conjugate pairs of eigenvalues. As ϵ decreases from 0 to -1, the number of real eigenvalues decreases; when $\epsilon \leq -0.57793$, the only real eigenvalue is the ground-state energy. As ϵ approaches -1^+, the ground-state energy becomes infinite. When $\epsilon \leq -1$ there are no real eigenvalues.

The class of $\mathcal{PT}$-symmetric Hamiltonians is larger than and includes real symmetric Hermitians because any real symmetric Hamiltonian is automatically $\mathcal{PT}$-symmetric. For example, consider the real symmetric Hamiltonian $H = p^2 + x^2 + 2x$. This Hamiltonian is time-reversal symmetric, but according to the usual definition of space reflection for which $x \to -x$, this Hamiltonian appears not to have $\mathcal{PT}$ symmetry. However, recall that the parity operator is defined only up to unitary equivalence. In this example, if we express the Hamiltonian in the form $H = p^2 + (x+1)^2 - 1$, then it is evident that H is $\mathcal{PT}$ symmetric, provided that the parity operator performs a space reflection about the point $x = -1$ rather than $x = 0$. See Ref. [2] for the construction of the relevant parity operator.

With properly defined boundary conditions the spectrum of the Hamiltonian H in (1) is *real and positive* when $\epsilon \geq 0$ [3] and the spectrum is partly real and partly complex when $\epsilon < 0$. The eigenvalues have been computed numerically to very high precision, and the real eigenvalues are plotted as functions of ϵ in Fig. 1.

We say that the $\mathcal{PT}$ symmetry of a Hamiltonian H is *unbroken* if all of the eigenfunctions of H are simultaneously eigenfunctions of $\mathcal{PT}$[2]. Here is a proof that if the $\mathcal{PT}$ symmetry of a Hamiltonian H is unbroken, then the spectrum of H is real: Assume that H possesses $\mathcal{PT}$ symmetry (that is, that H commutes with the $\mathcal{PT}$ operator), and that if ϕ is an eigenstate of H with eigenvalue E, then it is simultaneously an eigenstate of $\mathcal{PT}$ with eigenvalue λ:

$$H\phi = E\phi \qquad \text{and} \qquad \mathcal{PT}\phi = \lambda\phi. \tag{2}$$

$H = p^2 + x^6(ix)^\epsilon$ along the path $\epsilon : 0 \to 4$. This is because the boundary conditions on the eigenfunctions are different.

[2] If a system is defined by an equation that possesses a discrete symmetry, the solution to this equation need not exhibit that symmetry. For example, the differential equation $\ddot{y}(t) = y(t)$ is symmetric under time reversal $t \to -t$. The solutions $y(t) = e^t$ and $y(t) = e^{-t}$ do not exhibit time-reversal symmetry while the solution $y(t) = \cosh(t)$ is time-reversal symmetric. The same is true with a system whose Hamiltonian is $\mathcal{PT}$ symmetric. Even if the Schrödinger equation and the corresponding boundary conditions are $\mathcal{PT}$ symmetric, the wave function that solves the Schrödinger equation boundary value problem may not be symmetric under space-time reflection. When the solution exhibits $\mathcal{PT}$ symmetry, we say that the $\mathcal{PT}$ symmetry is unbroken. Conversely, if the solution does not possess $\mathcal{PT}$ symmetry, we say that the $\mathcal{PT}$ symmetry is broken.

We begin by showing that the eigenvalue λ is a pure phase. Multiply $\mathcal{PT}\phi = \lambda\phi$ on the left by $\mathcal{PT}$ and use the fact that $\mathcal{P}$ and $\mathcal{T}$ commute and that $\mathcal{P}^2 = \mathcal{T}^2 = 1$ to conclude that $\phi = \lambda^*\lambda\phi$ and thus $\lambda = e^{i\alpha}$ for some real α. Next, introduce a convention that we use throughout this talk. Without loss of generality we replace the eigenstate ϕ by $e^{-i\alpha/2}\phi$ so that its eigenvalue under the operator $\mathcal{PT}$ is unity: $\mathcal{PT}\phi = \phi$. Next, multiply the eigenvalue equation $H\phi = E\phi$ on the left by $\mathcal{PT}$ and use $[\mathcal{PT}, H] = 0$ to obtain $E\phi = E^*\phi$. Hence, $E = E^*$ and E is real.

The crucial assumption in this argument is that ϕ is simultaneously an eigenstate of H and $\mathcal{PT}$. In quantum mechanics if a linear operator X commutes with H, then the eigenstates of H are also eigenstates of X. However, the operator $\mathcal{PT}$ is not linear (it is antilinear) and thus we must make the extra assumption that the $\mathcal{PT}$ symmetry of H is unbroken; that is, that ϕ is simultaneously an eigenstate of H and $\mathcal{PT}$. This extra assumption is nontrivial because it is hard to determine *a priori* whether the $\mathcal{PT}$ symmetry of a given H is broken or unbroken. For the Hamiltonian H in (1) the $\mathcal{PT}$ symmetry is unbroken when $\epsilon \geq 0$ and broken when $\epsilon < 0$. The conventional Hermitian Hamiltonian for the quantum mechanical harmonic oscillator lies at the boundary of the unbroken and the broken regimes. Recently, Dorey *et al.* proved rigorously that the spectrum of H in (1) is real and positive [4] in the region $\epsilon \geq 0$. Many other $\mathcal{PT}$-symmetric Hamiltonians for which space-time reflection symmetry is not broken have been investigated, and the spectra of these Hamiltonians have also been shown to be real and positive [5].

While it is useful to show that a given non-Hermitian $\mathcal{PT}$-symmetric Hamiltonian operator has a positive real spectrum, the urgent question is whether such a Hamiltonian defines a physical theory of quantum mechanics. By a *physical theory* we mean that there is a Hilbert space of state vectors and that this Hilbert space has an inner product with a positive norm. In quantum mechanics we interpret the norm of a state as a probability and this probability must be positive. Furthermore, we must show that the time evolution of the theory is unitary. This means that as a state vector evolves in time the probability does not leak away.

It is not obvious whether a Hamiltonian such as H in (1) gives a consistent quantum theory. Indeed, past investigations of this Hamiltonian have shown that while the spectrum is entirely real and positive when $\epsilon \geq 0$, one inevitably encountered the severe problem of Hilbert spaces endowed with indefinite metrics [6]. We will identify a new symmetry that all $\mathcal{PT}$-symmetric Hamiltonians having an unbroken $\mathcal{PT}$-symmetry possess. We denote the operator representing this symmetry by $\mathcal{C}$ because the properties of this operator resemble those of the charge conjugation operator in particle physics. This will allow us to introduce an inner product structure associated with $\mathcal{CPT}$ conjugation for which the norms of quantum states are positive definite. We will see that $\mathcal{CPT}$ symmetry is an alternative to Hermiticity; it introduces the new concept of a *dynamically determined* inner product (one that is defined by the Hamiltonian itself). As a consequence, we will extend the Hamiltonian and its eigenstates into the complex domain so that the associated eigenvalues are real and the underlying dynamics is unitary.

2 Construction of the $\mathcal{C}$ operator

We begin by summarizing the mathematical properties of the solution to the Sturm–Liouville differential equation eigenvalue problem

$$-\phi_n''(x) + x^2(ix)^\epsilon\phi_n(x) = E_n\phi_n(x) \tag{3}$$

associated with the Hamiltonian H in (1). This differential equation must be imposed on an infinite contour in the complex-x plane. For large $|x|$ this contour lies in wedges placed symmetrically with respect to the imaginary-x axis [3]. The boundary conditions on the eigenfunctions are that $\phi(x) \to 0$ exponentially rapidly as $|x| \to \infty$ on the contour. For $0 \leq \epsilon < 2$, the contour may lie on the real axis.

When $\epsilon \geq 0$, the Hamiltonian has an unbroken $\mathcal{PT}$ symmetry. Thus, the eigenfunctions $\phi_n(x)$ are simultaneously eigenstates of the $\mathcal{PT}$ operator: $\mathcal{PT}\phi_n(x) = \lambda_n\phi_n(x)$. As we argued above, λ_n is a pure phase and, without loss of generality, for each n this phase can be absorbed into $\phi_n(x)$ by a multiplicative rescaling so that the new eigenvalue is unity:

$$\mathcal{PT}\phi_n(x) = \phi_n^*(-x) = \phi_n(x). \tag{4}$$

There is strong evidence that, when properly normalized, the eigenfunctions $\phi_n(x)$ are complete. The coordinate-space statement of completeness reads

$$\sum_n (-1)^n \phi_n(x)\phi_n(y) = \delta(x-y) \qquad (x, y \text{ real}). \tag{5}$$

This nontrivial result has been verified numerically to extremely high accuracy (twenty decimal places) [7, 8]. There is a factor of $(-1)^n$ in the sum. This unusual factor does not appear in conventional quantum mechanics. The presence of this factor is explained in the following discussion of orthonormality [see (7)].

Here is where we encounter the problem associated with non-Hermitian $\mathcal{PT}$-symmetric Hamiltonians. The obvious choice for the inner product of two functions $f(x)$ and $g(x)$ is

$$(f, g) \equiv \int dx\, [\mathcal{PT} f(x)]g(x), \tag{6}$$

where $\mathcal{PT} f(x) = [f(-x)]^*$ and the integral path is the above contour in the complex-x plane. The apparent advantage of this inner product is that the associated norm (f, f) is independent of the overall phase of $f(x)$ and is conserved in time. Phase independence is desired because in quantum mechanics the objective is to construct a space of rays to represent quantum mechanical states. With respect to this inner product the eigenfunctions $\phi_m(x)$ and $\phi_n(x)$ of H in (1) are orthogonal for $n \neq m$. However, when $m = n$ the norm is evidently *not positive*:

$$(\phi_m, \phi_n) = (-1)^n \delta_{mn}. \tag{7}$$

This result is apparently true for all values of ϵ in (3) and it has been verified numerically to extremely high precision. Because the norms of the eigenfunctions alternate in sign, the metric associated with the $\mathcal{PT}$ inner product $(\cdot, \cdot)$ is indefinite. This split signature (sign alternation) is a *generic* feature of the $\mathcal{PT}$ inner product. Extensive numerical calculations verify that the formula in (7) holds for all $\epsilon \geq 0$.

Despite the lack of positivity of the inner product, we proceed with the usual analysis that one would perform for any Sturm–Liouville problem of the form $H\phi_n = E_n\phi_n$. First, we use the inner product formula (7) to verify that (5) is the representation of the unity operator. That is, we verify that $\int dy\, \delta(x-y)\delta(y-z) = \delta(x-z)$.

Second, we reconstruct the parity operator $\mathcal{P}$ in terms of the eigenstates. The parity operator in position space is $\mathcal{P}(x, y) = \delta(x+y)$, so from (5) we get

$$\mathcal{P}(x, y) = \sum_n (-1)^n \phi_n(x)\phi_n(-y). \tag{8}$$

By virtue of (7) the square of the parity operator is unity: $\mathcal{P}^2 = 1$.

Third, we construct H in coordinate space: $H(x, y) = \sum_n (-1)^n E_n \phi_n(x)\phi_n(y)$. Using (5)–(7) we can see that this Hamiltonian satisfies $H\phi_n(x) = E_n\phi_n(x)$.

Fourth, we construct the Green's function $G(x, y) = \sum_n (-1)^n \frac{1}{E_n}\phi_n(x)\phi_n(y)$ in coordinate space. The Green's function is the functional inverse of H; that is, G satisfies

$$\int dy\, H(x, y)G(y, z) = \left[-\frac{d^2}{dx^2} + x^2(ix)^\epsilon\right] G(x, z) = \delta(x-z). \tag{9}$$

While the time-independent Schrödinger equation (3) cannot be solved analytically, the differential equation for $G(x,z)$ in (9) *can* be solved in closed form [8]. The technique is to consider the case $0<\epsilon<2$ so that we may treat x as real and then to decompose the x axis into two regions, $x>z$ and $x<z$. We can solve the differential equation in each region in terms of Bessel functions. From this representation of the Green's function we construct an exact closed-form expression for the *spectral zeta function* (sum of the inverses of the energy eigenvalues). To do so we set $y=x$ in $G(x,y)$ and use (7) to integrate over x. For all $\epsilon>0$ we obtain [8]

$$\sum_n \frac{1}{E_n} = \left[1+\frac{\cos\left(\frac{3\epsilon\pi}{2\epsilon+8}\right)\sin\left(\frac{\pi}{4+\epsilon}\right)}{\cos\left(\frac{\epsilon\pi}{4+2\epsilon}\right)\sin\left(\frac{3\pi}{4+\epsilon}\right)}\right]\frac{\Gamma\left(\frac{1}{4+\epsilon}\right)\Gamma\left(\frac{2}{4+\epsilon}\right)\Gamma\left(\frac{\epsilon}{4+\epsilon}\right)}{(4+\epsilon)^{\frac{4+2\epsilon}{4+\epsilon}}\Gamma\left(\frac{1+\epsilon}{4+\epsilon}\right)\Gamma\left(\frac{2+\epsilon}{4+\epsilon}\right)}. \tag{10}$$

Having presented these general Sturm–Liouville constructions, we now address the crucial question of whether a $\mathcal{PT}$-symmetric Hamiltonian defines a physically viable quantum mechanics or whether it merely provides an intriguing Sturm–Liouville eigenvalue problem. The apparent difficulty with formulating a quantum theory is that the vector space of quantum states is spanned by energy eigenstates, of which half have norm $+1$ and half have norm -1. Because the norm of the states carries a probabilistic interpretation in standard quantum theory, the existence of an indefinite metric in (7) seems to be a serious obstacle.

The situation here in which half of the energy eigenstates have positive norm and half have negative norm is analogous to the problem that Dirac encountered in formulating the spinor wave equation in relativistic quantum theory [9]. Following Dirac's approach, we attack the problem of an indefinite norm by finding a physical interpretation for the negative norm states. We claim that in *any* theory having an unbroken $\mathcal{PT}$ symmetry there exists a symmetry of the Hamiltonian connected with the fact that there are equal numbers of positive-norm and negative-norm states. To describe this symmetry we construct a linear operator denoted by $\mathcal{C}$ and represented in position space as a sum over the energy eigenstates of the Hamiltonian [10]:

$$\mathcal{C}(x,y)=\sum_n \phi_n(x)\phi_n(y). \tag{11}$$

As stated earlier, the properties of this new operator $\mathcal{C}$ resemble those of the charge conjugation operator in quantum field theory. For example, we can use (5)–(7) to verify that the square of $\mathcal{C}$ is unity ($\mathcal{C}^2=1$): $\int dy\,\mathcal{C}(x,y)\mathcal{C}(y,z)=\delta(x-z)$. Thus, the eigenvalues of $\mathcal{C}$ are ±1. Also, $\mathcal{C}$ commutes with the Hamiltonian H. Therefore, since $\mathcal{C}$ is linear, the eigenstates of H have definite values of $\mathcal{C}$. Specifically, if the energy eigenstates satisfy (7), then we have $\mathcal{C}\phi_n=(-1)^n\phi_n$ because

$$\mathcal{C}\phi_n(x)=\int dy\,\mathcal{C}(x,y)\phi_n(y)=\sum_m \phi_m(x)\int dy\,\phi_m(y)\phi_n(y).$$

We then use $\int dy\,\phi_m(y)\phi_n(y)=(\phi_m,\phi_n)$ according to our convention. Thus, $\mathcal{C}$ is the operator observable that represents the measurement of the signature of the $\mathcal{PT}$ norm of a state[3].

The operators $\mathcal{P}$ and $\mathcal{C}$ are distinct square roots of the unity operator $\delta(x-y)$. That is, $\mathcal{P}^2=\mathcal{C}^2=1$, but $\mathcal{P}\neq\mathcal{C}$. Indeed, $\mathcal{P}$ is real, while $\mathcal{C}$ is complex[4]. Furthermore, these two operators do not commute; in the position representation

$$(\mathcal{CP})(x,y)=\sum_n \phi_n(x)\phi_n(-y) \qquad \text{but} \qquad (\mathcal{PC})(x,y)=\sum_n \phi_n(-x)\phi_n(y), \tag{12}$$

which shows that $\mathcal{CP}=(\mathcal{PC})^*$. However, $\mathcal{C}$ *does* commute with $\mathcal{PT}$.

[3]The $\mathcal{PT}$ norm of a state determines its parity type. We can regard $\mathcal{C}$ as representing the operator that determines the $\mathcal{C}$ charge of the state. Quantum states having opposite $\mathcal{C}$ charge possess opposite parity type.

[4]The parity operator in coordinate space is explicitly real $\mathcal{P}(x,y)=\delta(x+y)$; the operator $\mathcal{C}(x,y)$ is complex because it is a sum of products of complex functions, as we see in (11). The complexity of the $\mathcal{C}$ operator can be seen explicitly in perturbative calculations of $\mathcal{C}(x,y)$ [11].

Finally, having obtained the operator $\mathcal{C}$ we define a new inner product structure having *positive definite* signature by

$$\langle f|g\rangle \equiv \int_{\rm C} dx\,[\mathcal{CPT}f(x)]g(x). \tag{13}$$

Like the $\mathcal{PT}$ inner product (6), this inner product is phase independent and conserved in time. This is because the time evolution operator, just as in ordinary quantum mechanics, is e^{iHt}. The fact that H commutes with the $\mathcal{PT}$ and the $\mathcal{CPT}$ operators implies that both inner products, (6) and (13), remain time independent as the states evolve in time. However, unlike (6), the inner product (13) is positive definite because $\mathcal{C}$ contributes -1 when it acts on states with negative $\mathcal{PT}$ norm. In terms of the $\mathcal{CPT}$ conjugate, the completeness condition (5) reads

$$\sum_n \phi_n(x)[\mathcal{CPT}\phi_n(y)] = \delta(x-y). \tag{14}$$

Unlike the inner product of conventional quantum mechanics, the $\mathcal{CPT}$ inner product (14) is *dynamically determined*; it depends implicitly on the Hamiltonian.

The operator $\mathcal{C}$ does not exist as a distinct entity in conventional quantum mechanics. Indeed, if we allow the parameter ϵ in (1) to tend to zero, the operator $\mathcal{C}$ in this limit becomes identical to $\mathcal{P}$. Thus, in this limit the $\mathcal{CPT}$ operator becomes $\mathcal{T}$, which is just complex conjugation. As a consequence, the inner product (13) defined with respect to the $\mathcal{CPT}$ conjugation reduces to the complex conjugate inner product of conventional quantum mechanics when $\epsilon \to 0$. Similarly, in this limit (14) reduces to the usual statement of completeness $\sum_n \phi_n(x)\phi_n^*(y) = \delta(x-y)$.

The $\mathcal{CPT}$ inner-product (13) is independent of the choice of integration contour C so long as C lies inside the asymptotic wedges associated with the boundary conditions for the Sturm–Liouville problem (2). Path independence follows from Cauchy's theorem and the analyticity of the integrand. In ordinary quantum mechanics, where the positive-definite inner product has the form $\int dx\, f^*(x)g(x)$, the integral must be taken along the real axis and the path of the integration cannot be deformed into the complex plane because the integrand is not analytic[5]. The $\mathcal{PT}$ inner product (6) shares with (13) the advantage of analyticity and path independence, but suffers from nonpositivity. We find it surprising that a positive-definite metric can be constructed using $\mathcal{CPT}$ conjugation without disturbing the path independence of the inner-product integral.

Finally, we explain why $\mathcal{PT}$-symmetric theories are unitary. Time evolution is determined by the operator e^{-iHt}, whether the theory is expressed in terms of a $\mathcal{PT}$-symmetric Hamiltonian or just an ordinary Hermitian Hamiltonian. To establish the global unitarity of a theory we must show that as a state vector evolves its norm does not change in time. If $\psi_0(x)$ is a prescribed initial wave function belonging to the Hilbert space spanned by the energy eigenstates, then it evolves into the state $\psi_t(x)$ at time t according to $\psi_t(x) = e^{-iHt}\psi_0(x)$. With respect to the $\mathcal{CPT}$ inner product defined in (13), the norm of the vector $\psi_t(x)$ does not change in time, $\langle\psi_t|\psi_t\rangle = \langle\psi_0|\psi_0\rangle$, because the Hamiltonian H commutes with the $\mathcal{CPT}$ operator.

Establishing unitarity at a local level is harder. Here, we must show that in coordinate space there exists a local probability density that satisfies a continuity equation so that the probability does not leak away. This is a subtle result because the probability current flows in the complex plane rather than along the real axis as in conventional Hermitian quantum mechanics. Preliminary numerical studies indeed indicate that the continuity equation is fulfilled [12].

[5]If a function satisfies a linear ordinary differential equation, then the function is analytic wherever the coefficient functions of the differential equation are analytic. The Schrödinger equation (3) is linear and its coefficients are analytic except for a branch cut at the origin; this branch cut can be taken to run up the imaginary axis. We choose the integration contour for the inner product (7) so that it does not cross the positive imaginary axis. Path independence occurs because the integrand of the inner product (7) is a product of analytic functions.

3 Illustrative example: A 2×2 matrix Hamiltonian

We illustrate the above results concerning $\mathcal{PT}$-symmetric quantum mechanics using the finite-dimensional 2×2 matrix Hamiltonian

$$H = \begin{pmatrix} re^{i\theta} & s \\ s & re^{-i\theta} \end{pmatrix}, \tag{15}$$

where the three parameters r, s, and θ are real. This Hamiltonian is not Hermitian in the usual sense, but it is $\mathcal{PT}$ symmetric, where the parity operator is [13]

$$\mathcal{P} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \tag{16}$$

and $\mathcal{T}$ performs complex conjugation.

There are two parametric regions for this Hamiltonian. When $s^2 < r^2 \sin^2\theta$, the energy eigenvalues form a complex conjugate pair. This is the region of broken $\mathcal{PT}$ symmetry. On the other hand, if $s^2 \geq r^2 \sin^2\theta$, then the eigenvalues $\varepsilon_\pm = r\cos\theta \pm \sqrt{s^2 - r^2\sin^2\theta}$ are real. This is the region of unbroken $\mathcal{PT}$ symmetry. In the unbroken region the simultaneous eigenstates of the operators H and $\mathcal{PT}$ are

$$|\varepsilon_+\rangle = \frac{1}{\sqrt{2\cos\alpha}} \begin{pmatrix} e^{i\alpha/2} \\ e^{-i\alpha/2} \end{pmatrix} \qquad \text{and} \qquad |\varepsilon_-\rangle = \frac{i}{\sqrt{2\cos\alpha}} \begin{pmatrix} e^{-i\alpha/2} \\ -e^{i\alpha/2} \end{pmatrix}, \tag{17}$$

where we set $\sin\alpha = (r/s)\sin\theta$. It is easily verified that $(\varepsilon_\pm, \varepsilon_\pm) = \pm 1$ and that $(\varepsilon_\pm, \varepsilon_\mp) = 0$, recalling that $(u, v) = (\mathcal{PT}u)\cdot v$. Therefore, with respect to the $\mathcal{PT}$ inner product, the resulting vector space spanned by energy eigenstates has a metric of signature $(+,-)$. The condition $s^2 > r^2\sin^2\theta$ ensures that $\mathcal{PT}$ symmetry is not broken. If this condition is violated, the states (17) are no longer eigenstates of $\mathcal{PT}$ because α becomes imaginary[6].

Next, we construct the operator $\mathcal{C}$:

$$\mathcal{C} = \frac{1}{\cos\alpha} \begin{pmatrix} i\sin\alpha & 1 \\ 1 & -i\sin\alpha \end{pmatrix}. \tag{18}$$

Note that $\mathcal{C}$ is distinct from H and $\mathcal{P}$ and has the key property that $\mathcal{C}|\varepsilon_\pm\rangle = \pm|\varepsilon_\pm\rangle$. The operator $\mathcal{C}$ commutes with H and satisfies $\mathcal{C}^2 = 1$. The eigenvalues of $\mathcal{C}$ are precisely the signs of the $\mathcal{PT}$ norms of the corresponding eigenstates. Using the operator $\mathcal{C}$ we construct the new inner product structure $\langle u|v\rangle = (\mathcal{CPT}u)\cdot v$. This inner product is positive definite because $\langle\varepsilon_\pm|\varepsilon_\pm\rangle = 1$. Thus, the two-dimensional Hilbert space spanned by $|\varepsilon_\pm\rangle$, with inner product $\langle\cdot|\cdot\rangle$, has a Hermitian structure with signature $(+,+)$.

Let us demonstrate explicitly that the $\mathcal{CPT}$ norm of any vector is positive. For the arbitrary vector $\psi = \binom{a}{b}$, where a and b are any complex numbers, we see that $\mathcal{T}\psi = \binom{a^*}{b^*}$, that $\mathcal{PT}\psi = \binom{b^*}{a^*}$, and that $\mathcal{CPT}\psi = \frac{1}{\cos\alpha}\binom{a^* + ib^*\sin\alpha}{b^* - ia^*\sin\alpha}$. Thus, $\langle\psi|\psi\rangle = (\mathcal{CPT}\psi)\cdot\psi = \frac{1}{\cos\alpha}[a^*a + b^*b + i(b^*b - a^*a)\sin\alpha]$. Now let $a = x + iy$ and $b = u + iv$, where x, y, u, and v are real. Then

$$\langle\psi|\psi\rangle = \left(x^2 + v^2 + 2xv\sin\alpha + y^2 + u^2 - 2yu\sin\alpha\right)/\cos(\alpha), \tag{19}$$

which is explicitly positive and vanishes only if $x = y = u = v = 0$.

Since $\langle u|$ denotes the $\mathcal{CPT}$-conjugate of $|u\rangle$, the completeness condition reads

$$|\varepsilon_+\rangle\langle\varepsilon_+| + |\varepsilon_-\rangle\langle\varepsilon_-| = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \tag{20}$$

[6]When $\mathcal{PT}$ symmetry is broken, we find that the $\mathcal{PT}$ norm of the energy eigenstate vanishes.

Furthermore, using the $\mathcal{CPT}$ conjugate $\langle\varepsilon_\pm|$, we have $\mathcal{C}$ as $\mathcal{C} = |\varepsilon_+\rangle\langle\varepsilon_+| - |\varepsilon_-\rangle\langle\varepsilon_-|$, instead of the representation in (11), which uses the $\mathcal{PT}$ conjugate.

We represent an observable in this theory by a $\mathcal{CPT}$-invariant operator; that is, one that commutes with $\mathcal{CPT}$. Thus, if $\mathcal{CPT}$ symmetry is not broken, the eigenvalues of the observable are real. The operator $\mathcal{C}$ satisfies this requirement, so it is an observable. For the two-state system, if we set $\theta = 0$, then the Hamiltonian (15) becomes Hermitian. However, $\mathcal{C}$ then reduces to the parity operator $\mathcal{P}$. As a consequence, the requirement of $\mathcal{CPT}$ invariance reduces to the standard condition of Hermiticity for a symmetric matrix, namely, that $H = H^*$. This is why the hidden symmetry $\mathcal{C}$ was not noticed previously. The operator $\mathcal{C}$ emerges only when we extend a real symmetric Hamiltonian into the complex domain.

We have also calculated the $\mathcal{C}$ operator in infinite-dimensional quantum mechanical models. For an $x^2 + ix^3$ potential $\mathcal{C}$ can be obtained from the summation in (11) using perturbative methods and for an $x^2 - x^4$ potential $\mathcal{C}$ can be calculated using nonperturbative methods [11].

4 Applications and possible observable consequences

Could non-Hermitian, $\mathcal{PT}$-symmetric Hamiltonians be used to describe experimentally observable phenomena? Non-Hermitian Hamiltonians have *already* been used to describe interacting systems. Wu showed that the ground state of a Bose system of hard spheres is described by a non-Hermitian Hamiltonian [14]. Wu found that the ground-state energy of this system is real and conjectured that all energy levels were real. Hollowood showed that even though the Hamiltonian of a complex Toda lattice is non-Hermitian, the energy levels are real [15]. Non-Hermitian Hamiltonians of the form $H = p^2 + ix^3$ also arise in various Reggeon field theory models that exhibit real positive spectra [16]. In these examples the fact that a non-Hermitian Hamiltonian had a real spectrum appeared mysterious at the time, but now we know why: In each case the non-Hermitian Hamiltonian is $\mathcal{PT}$-symmetric. In each case the Hamiltonian constructed so that the position operator x or the field operator ϕ is always multiplied by i.

An experimental signal of a complex Hamiltonian might be found in the context of condensed matter physics. Consider the complex crystal lattice whose potential is $V(x) = i\sin x$. While the Hamiltonian $H = p^2 + i\sin x$ is not Hermitian, it is $\mathcal{PT}$-symmetric, and all of the energy bands are *real*. However, at the edge of the bands the wave function of a particle in such a lattice is always bosonic (2π-periodic) and, unlike the case of ordinary crystal lattices, the wave function is never fermionic (4π-periodic) [17]. Direct observation of such a band structure would give unambiguous evidence of a $\mathcal{PT}$-symmetric Hamiltonian.

There are many opportunities for the use of non-Hermitian Hamiltonians in the study of quantum field theory. For example, a scalar quantum field theory with a cubic self-interaction described by the Lagrangian $\mathcal{L} = \frac{1}{2}(\nabla\varphi)^2 + \frac{1}{2}m^2\varphi^2 + g\varphi^3$ is physically unacceptable because the energy spectrum is not bounded below. However, the cubic scalar quantum field theory that corresponds to H in (1) with $\epsilon = 1$ is given by the Lagrangian density $\mathcal{L} = \frac{1}{2}(\nabla\varphi)^2 + \frac{1}{2}m^2\varphi^2 + ig\varphi^3$. This is a new, physically acceptable quantum field theory. Moreover, the theory that corresponds to H in (1) with $\epsilon = 2$ is described by the Lagrangian density

$$\mathcal{L} = \frac{1}{2}(\nabla\varphi)^2 + \frac{1}{2}m^2\varphi^2 - \frac{1}{4}g\varphi^4. \tag{21}$$

This "wrong-sign" field theory is remarkable because, in addition to the energy spectrum being real and positive, the one-point Green's function (the vacuum expectation value of the field φ) is *nonzero* [18]. Also, the field theory is renormalizable, and in four dimensions is asymptotically free (and thus nontrivial) [19]. Based on these features, we believe that the theory may provide a setting to describe the dynamics of the Higgs sector in the standard model.

Other field theory models whose Hamiltonians are non-Hermitian and $\mathcal{PT}$-symmetric have also been studied. For example, $\mathcal{PT}$-symmetric electrodynamics is particularly interesting because it is asymptotically free (unlike ordinary electrodynamics) and because the direction of the Casimir force is the negative of that in ordinary electrodynamics [20]. This theory is remarkable because it can determine its own coupling constant. Supersymmetric $\mathcal{PT}$-symmetric quantum field theories have also been studied [21].

We have found that $\mathcal{PT}$-symmetric quantum theories exhibit surprising and new phenomena. For example, for g sufficiently small the $-g\varphi^4$ theory described by the Lagrangian (21) possesses bound states (the conventional $g\varphi^4$ theory does not because the potential is repulsive). The bound states occur for all dimensions $0 \leq D < 3$ [22], but for purposes of illustration we describe the bound states in the context of one-dimensional quantum field theory (quantum mechanics). For the conventional anharmonic oscillator, which is described by the Hamiltonian

$$H = \frac{1}{2}p^2 + \frac{1}{2}m^2x^2 + \frac{1}{4}gx^4 \qquad (g > 0), \tag{22}$$

the small-g Rayleigh-Schrödinger perturbation series for the kth energy level E_k is

$$E_k \sim m\left[k + \frac{1}{2} + \frac{3}{4}(2k^2 + 2k + 1)\nu + \mathrm{O}\left(\nu^2\right)\right] \qquad (\nu \to 0^+), \tag{23}$$

where $\nu = g/(4m^3)$. The *renormalized mass* M is defined as the first excitation above the ground state: $M \equiv E_1 - E_0 \sim m\big[1 + 3\nu + \mathrm{O}\big(\nu^2\big)\big]$ as $\nu \to 0^+$.

To determine if the two-particle state is bound, we examine the second excitation above the ground state using (23). We define

$$B_2 \equiv E_2 - E_0 \sim m\left[2 + 9\nu + \mathrm{O}\left(\nu^2\right)\right] \qquad (\nu \to 0^+). \tag{24}$$

If $B_2 < 2M$, then a two-particle bound state exists and the (negative) binding energy is $B_2 - 2M$. If $B_2 > 2M$, then the second excitation above the vacuum is interpreted as an unbound two-particle state. From (24) we see that in the small-coupling region, where perturbation theory is valid, the conventional anharmonic oscillator does not possess a bound state. Indeed, using WKB, variational methods, or numerical calculations, one can show that there is no two-particle bound state for any value of $g > 0$. Because there is no bound state the gx^4 interaction may be considered to represent a repulsive force[7].

The perturbation series for the non-Hermitian, $\mathcal{PT}$-symmetric Hamiltonian

$$H = \frac{1}{2}p^2 + \frac{1}{2}m^2x^2 - \frac{1}{4}gx^4 \qquad (g > 0), \tag{25}$$

is obtained from the perturbation series for the conventional anharmonic oscillator by replacing $\nu \to -\nu$. Thus, while the conventional anharmonic oscillator does not possess a two-particle bound state, the $\mathcal{PT}$-symmetric oscillator does indeed possess such a state. We measure the binding energy of this state in units of the renormalized mass M and we define the *dimensionless* binding energy Δ_2 by

$$\Delta_2 \equiv (B_2 - 2M)/M \sim -3\nu + \mathrm{O}\left(\nu^2\right) \qquad (\nu \to 0^+). \tag{26}$$

This bound state disappears when ν increases beyond $\nu = 0.0465$. As ν continues to increase, Δ_2 reaches a maximum value of 0.427 at $\nu = 0.13$ and then approaches 0.28 as $\nu \to \infty$.

[7] In general, a repulsive force in a quantum field theory is represented by an energy dependence in which the energy of a two-particle state decreases with separation. The conventional anharmonic oscillator Hamiltonian corresponds to a field theory in one space-time dimension, where there cannot be any spatial dependence. In this case the repulsive nature of the force is understood to mean that the energy B_2 needed to create two particles at a given time is more than twice the energy M needed to create one particle.

In the $\mathcal{PT}$-symmetric anharmonic oscillator, there are not only two-particle bound states but also k-particle bound states for all $k \geq 2$. The dimensionless binding energies are

$$\Delta_k \equiv (B_k - kM)/M \sim -3k(k-1)\nu/2 + \mathrm{O}\left(\nu^2\right) \qquad (\nu \to 0+). \tag{27}$$

The coefficient of ν is negative. Since the dimensionless binding energy becomes negative as ν increases from 0, there is a k-particle bound state. The higher multiparticle bound states cease to be bound for smaller values of ν; starting with the three-particle bound state, the binding energy of these states becomes positive as ν increases past 0.039, 0.034, 0.030, and 0.027.

Thus, for any value of ν there are always a finite number of bound states and an infinite number of unbound states. The number of bound states decreases with increasing ν until there are no bound states at all. There is a range of ν for which there are only two- and three-particle bound states, just like the physical world in which one observes only states of two and three bound quarks. In this range of ν if one has an initial state containing a number of particles (renormalized masses), these particles will clump together into bound states, releasing energy in the process. Depending on the value of ν, the final state will consist either of two- or of three-particle bound states, whichever is energetically favored. There is a special value of ν for which two- and three-particle bound states can exist in thermodynamic equilibrium.

How does a $g\varphi^3$ theory compare with a $g\varphi^4$ theory? A $g\varphi^3$ theory has an attractive force. Bound states arising as a consequence of this force can be found by using the Bethe–Salpeter equation. However, the $g\varphi^3$ field theory is unacceptable because the spectrum is not bounded below. If we replace g by ig, the spectrum becomes real and positive, but now the force becomes repulsive and there are no bound states. The same is true for a two-scalar theory with interaction of the form $ig\varphi^2\chi$, which is a model of scalar electrodynamics that has no analog of positronium.

Another feature of $\mathcal{PT}$-symmetric quantum field theory that distinguishes it from conventional quantum field theory is the commutation relation between the $\mathcal{P}$ and $\mathcal{C}$ operators. If we write $\mathcal{C} = \mathcal{C}_{\mathrm{R}} + i\mathcal{C}_{\mathrm{I}}$, where $\mathcal{C}_{\mathrm{R}}$ and $\mathcal{C}_{\mathrm{I}}$ are real, then $\mathcal{C}_{\mathrm{R}}\mathcal{P} = \mathcal{P}\mathcal{C}_{\mathrm{R}}$ and $\mathcal{C}_{\mathrm{I}}\mathcal{P} = -\mathcal{P}\mathcal{C}_{\mathrm{I}}$. These commutation and anticommutation relations suggest the possibility of interpreting $\mathcal{PT}$-symmetric quantum field theory as describing both bosonic and fermionic degrees of freedom, an idea analogous to the supersymmetric quantum theories. The distinction here, however, is that the supersymmetry can be broken; that is, bosonic and fermionic counterparts can have different masses without breaking the $\mathcal{PT}$ symmetry. Therefore, another possible observable experimental consequence might be the breaking of the supersymmetry.

5 Concluding remarks

We have described an alternative to the axiom of standard quantum mechanics that the Hamiltonian must be Hermitian. We have shown that Hermiticity may be replaced by the more physical condition of $\mathcal{PT}$ (space-time reflection) symmetry. Space-time reflection symmetry is distinct from the condition of Hermiticity, so it is possible to consider new quantum theories, such as quantum field theories whose self-interaction potentials are $ig\varphi^3$ or $-g\varphi^4$. Such theories have previously been thought to be mathematically and physically unacceptable because the spectrum might not be real and because the time evolution might not be unitary.

These new theories are complex extensions of ordinary quantum mechanics; they are continuations of real symmetric Hamiltonians to complex Hamiltonians. The idea of analytically continuing a Hamiltonian was first discussed by Dyson, who argued heuristically that perturbation theory for quantum electrodynamics diverges [23]. Dyson's argument involves rotating the electric charge e into the complex plane $e \to ie$. Applied to the anharmonic oscillator (22), Dyson's argument goes: If the coupling constant g is continued in the complex-g plane to $-g$, then the potential is no longer bounded below, so the resulting theory has no ground state. Thus, the ground-state energy $E_0(g)$ has an abrupt transition at $g = 0$. As a series in powers

of g, $E_0(g)$ must have a zero radius of convergence because $E_0(g)$ is singular at $g = 0$. Hence, the perturbation series must diverge for all $g \neq 0$. The perturbation series does indeed diverge, but this argument is flawed because the spectrum of the Hamiltonian (25) remains ambiguous until the boundary conditions that the wave functions must satisfy are specified. The spectrum depends crucially on how this Hamiltonian with a negative coupling constant is obtained.

There are two ways to obtain H in (25). First, one can substitute $g = |g|e^{i\theta}$ into (22) and rotate from $\theta = 0$ to $\theta = \pi$. Under this rotation, the ground-state energy $E_0(g)$ becomes complex. Evidently, $E_0(g)$ is real and positive when $g > 0$ and complex when $g < 0$[8]. Second, one can obtain (25) as a limit of the Hamiltonian

$$H = \frac{1}{2}p^2 + \frac{1}{2}m^2x^2 + \frac{1}{4}gx^2(ix)^\epsilon \qquad (g > 0) \tag{28}$$

as $\epsilon : 0 \to 2$. The spectrum of this Hamiltonian is real, positive, and discrete. The spectrum of the limiting H in (25) obtained in this manner is similar in structure to that of H in (22).

How can H in (25) possess two such astonishingly different spectra? The answer lies in the boundary conditions on the wave functions $\phi_n(x)$. In the first case, in which $\theta = \arg g$ is rotated in the complex-g plane from 0 to π, $\psi_n(x)$ vanishes in the complex-x plane as $|x| \to \infty$ inside the wedges $-\pi/3 < \arg x < 0$ and $-4\pi/3 < \arg x < -\pi$. In the second case, in which the exponent ϵ ranges from 0 to 2, $\phi_n(x)$ vanishes in the complex-x plane as $|x| \to \infty$ inside the wedges $-\pi/3 < \arg x < 0$ and $-\pi < \arg x < -2\pi/3$. In this second case the boundary conditions hold in wedges that are symmetric with respect to the imaginary axis; these boundary conditions enforce the $\mathcal{PT}$ symmetry of H and are responsible for the reality of the energy spectrum.

Apart from the spectra, there is another striking difference between the two theories corresponding to H in (25). The one-point Green's function $G_1(g)$ is defined as the expectation value of the operator x in the ground-state wave function $\phi_0(x)$,

$$G_1(g) = \langle 0|x|0\rangle / \langle 0|0\rangle \equiv \int_C dx\, x\psi_0^2(x) \Big/ \int_C dx\, \psi_0^2(x), \tag{29}$$

where C is a contour that lies in the asymptotic wedges described above. The value of $G_1(g)$ for H in (25) depends on the limiting process by which we obtain H. If we substitute $g = g_0e^{i\theta}$ into the Hamiltonian (22) and rotate from $\theta = 0$ to $\theta = \pi$, we find that $G_1(g) = 0$ for all g on the semicircle in the complex-g plane. Thus, this rotation in the g plane preserves parity symmetry ($x \to -x$). However, if we define H in (25) by using the Hamiltonian in (28) and by allowing ϵ to range from 0 to 2, we find that $G_1(g) \neq 0$. Indeed, $G_1(g) \neq 0$ for *all* values of $\epsilon > 0$. Thus, in this theory $\mathcal{PT}$ symmetry (reflection about the imaginary axis, $x \to -x^*$) is preserved, but parity symmetry is permanently broken. Hence, one might be able to describe the dynamics of the Higgs sector by using a $-g\varphi^4$ quantum field theory.

We put forward the multiple point principle as a fine-tuning mechanism that can explain why the parameters of the standard model have the values observed experimentally. The principle states that the parameter values realized in Nature coincide with the surface (e.g. the point) in the action parameter space that lies in the boundary that separates the maximum number of regulator-induced phases (e.g., the lattice artifact phases of a lattice gauge theory). We argue that a mild form of non-locality – namely that embodied in allowing diffeomorphism invariant contributions to the action – seems to appear in any fine-tuning problem. We demonstrate that the multiple point principle solution to fine-tuning has the very special property of avoiding the paradoxes that can arise in the presence of non-locality.

1 Introduction

The Multiple Point Principle (MPP) states that fundamental physical parameters assume values that correspond to having a maximal number of different coexisting "phases" for the physically realized vacuum. There is phenomenological evidence suggesting that some or all of the about 20 parameters in the Standard Model (SM) that are not predicted within the framework of the SM correspond to the MPP values of these parameters [1–3]. That these parameters take on special values (i.e., the multiple point values) poses from one viewpoint a fine tuning problem (why do constants of Nature take the MPP values). From another viewpoint, assuming the MPP as a law of Nature leads to a mechanism for fine-tuning. It is the latter viewpoint that is developed here. Moreover, we shall argue that a mild form of non locality is inherent to fine-tuning problems in general. We therefore develop a model for the relationship between fine-tuning, non-locality and the MPP.

2 Fine-tuning seems to require some form of non-locality

Explaining the (dressed) value of the cosmological constant is an example of a fine-tuning problem that would seem to require the breakdown of locality at least in a mild sense. As with any fine-tuning problem, the cosmological constant problem calls for a way to make the coupling dynamical in such a way that the values of such couplings are maintained at constant values (required for translational invariance). But this leads to a problem: if a coupling (e.g., the cosmological constant) is dynamical, the demands of a strictly local theory would be that the bare coupling can only depend on the space-time point in question and indirectly on the past but certainly not on the future. However, if the bare cosmological constant (that is to be dynamically maintained at a constant value) immediately following the big bang is to already have its value fine-tuned once and for all – to say 120 decimal places – to the value that makes the dressed cosmological constant so small as suggested phenomenologically, we definitely have a problem with locality.

The problem is that the bare cosmological constant is relatable to the value of the dressed cosmological constant only if the details of the dressed cosmological constant (that did not exist when the bare value was already tuned to the valued required for the dressed vacuum) that will evolve in the future are known at the time of big bang [4]. We are forced to conclude that a strict principle of locality is not allowed if we want to have a dynamically maintained bare coupling and renormalization group corrections of a quantum field theory with a well-defined vacuum.

This suggests models with a mild form of non-locality consisting of an interaction that is the same between any pair of points in space-time independent of the distance between these points. Assuming that this sort of non-locality is manifested through a non-local action $\hat{S}_{\rm nl}$, this symmetry between any pair of space-time points (i.e., identical interaction regardless of separation) is insured by requiring the invariance of $\hat{S}_{\rm nl}$ under diffeomorphisms (reparameterization invariance). The non-local action $\hat{S}_{nl}$ is a function of functionals $I_{f_j}[\phi(x)]$: $\hat{S}_{\rm nl} = \hat{S}_{\rm nl}(\{I_{f_j}[\phi(x)\})$ where $I_{f_j}[\phi(x)] \stackrel{\rm def}{=} \int dx^4\sqrt{g(x)}f_j(\phi(x))$ and $f_j(\phi)$ might typically be a Lagrange density e.g., $f_j(\phi) = \mathcal{L}_j(\phi(x), \partial_\mu\phi(x))$. The symbol $\phi(x)$ stands for all the fields (and derivatives of same) of the theory.

An example of a nonlocal action would be any nonlinear function of the (reparameterization invariant) functionals $I_{f_i}, I_{f_j}, \ldots$; e.g., a term $\int d^4x \int d^4y\sqrt{g(x)g(y)}\phi^2(x)\phi^4(y)$. Another example of a non-local (and nonlinear) action term more relevant to this paper is associated with having fixed values $I_{\text{fixed } f_j}$ (fixed in the sense of being a law of Nature) of some extensive quantities $I_{f_j}[\phi]$. This amounts to having a δ-function term $\exp(S_{\rm nl}(\{I_{f_j}\}) = \prod_j \delta(I_{f_j}[\phi] - I_{\text{fixed } f_j})$ in the functional integration measure and results in the non-locality that, strictly speaking, is inherent to any microcanonical ensemble (but which often is "approximated away" by using a canonical ensemble when phase space volume (or functional integration measure) is a sufficiently rapidly varying function of the extensive quantities).

An extensive quantity $I_{f_j}[\phi(x)]$ has a value for each imaginable Feynman path integral history of the Universe as it evolves from Big Bang to Big Crunch. The value $I_{\text{fixed } f_j}$ is by assumption "frozen in" and cannot change during the lifetime of the Universe. This unchangeable "choice" $I_{\text{fixed } f_j}$ then singles out a subset of all possible Feynman path integral histories that is consistent with the space-time evolution of our actually realized Universe having $I_{f_j}[\phi] = I_{\text{fixed } f_j}$.

An interaction that is the same between the fields at *any* pair of space-time points – regardless of separation – would not likely be perceived as a non-local interaction. Rather such space-time omnipresent fields – a sort of background that is forever everywhere the same – would likely be interpreted as simply constants of Nature. This feature is reminiscent of baby universe theory the essence of which is that a physical constant can depend on something and still be a constant as a function of space-time.

3 The Multiple Point Principle (MPP)

The MPP was originally put forward in connection with theoretical predictions for the values of the three gauge coupling constants [1, 2]. In addition to the assumption of the MPP, we also assumed in this first application of MPP our so-called Anti-GUT gauge group $G_{\rm Anti-GUT}$ which consists of the 3-fold replication of the Standard Model Group (SMG): $G_{\rm Anti-GUT} = {\rm SMG}\otimes{\rm SMG}\otimes{\rm SMG} \stackrel{\rm def}{=} {\rm SMG}^3$ (in the extended version: $({\rm SMG}\times U(1))^3$) having one SMG factor for each generation of fermions and gauge bosons. We postulate that $G_{\rm Anti-GUT}$ is broken to the diagonal subgroup (i.e., the usual SMG) at roughly the Planck scale.

In the original context of predicting the standard model gauge couplings using MPP (originally referred to as the principle of multiple point criticality), the principle asserts that the Planck scale values of the standard model gauge group couplings coincide with the multiple point, i.e., the point that lies in the boundary separating the maximum number of phases in

the action parameter space corresponding to the gauge group $G_{\mathrm{Anti-GUT}}$. The (Planck scale) predictions for the gauge couplings are subsequently identified with the parameter values at the point in the action parameter space for the diagonal subgroup of $G_{\mathrm{Anti-GUT}}$ that is inherited from the multiple point for $G_{\mathrm{Anti-GUT}}$ after the Planck scale breakdown of the latter.

The idea was developed in the context of lattice gauge theory and the phases to which we refer are usually dismissed as lattice artifacts (e.g., a Higgsed phase, a confined or Coulomb-like phase). Such phases have been studied extensively in the literature for simple gauge groups and semi simple gauge groups with discrete subgroups (e.g. $SU(2)$ and $SU(3)$). One typically finds first order phase transitions between confined and Coulomb-like phases at critical values of the action parameters.

Taking such lattice artifact phases as physical reflects our suspicion that such phases are inherent to having a regulator. As a regulator in some form (be it a lattice, strings or whatever) is always needed for the consistency of any quantum field theory, it is consistent to assume the existence of a fundamental regulator. The "artifact" phases that arise in a theory with such a fundamental regulator (that we have chosen to implement as a fundamental lattice) are accordingly taken as ontological phases that have physical significance at the scale of the fundamental regulator (e.g., lattice). The assumption of an ontological fundamental regulator implies the existence of monopoles in terms of which the regulator induced phase can also be studied [5].

Finding the multiple point in an action parameter space corresponding to the gauge group $G_{\mathrm{Anti-GUT}}$ is more complicated than for a single $SU(2)$ or $SU(3)$ say. The boundaries between phases in the action parameter space (i.e., the phase diagram) must be sought in a high dimensional parameter space essentially because $G_{\mathrm{Anti-GUT}}$ being a non-simple group has many subgroups and invariant subgroups.

In fact, there is a distinct phase for each subgroup pair (K, H), where K is a subgroup and H is an invariant subgroup such that $H \lhd K \subseteq G_{\mathrm{Anti-GUT}}$. An element $U \in G_{\mathrm{Anti-GUT}}$ can be parameterized as $U = U(g, k, h)$ where the Higgsed (gauge) degrees of freedom are elements g of the homogeneous space $G_{\mathrm{Anti-GUT}}/K$. The (un-Higgsed) Coulomb-like and confined degrees of freedom are respectively the elements k of the factor group K/H and the elements $h \in H$.

4 A familiar analogy to the MPP as a fine-tuning mechanism

Some important features of the MPP as a fine-tuning mechanism can be illustrated using an analogy to the familiar system in which the solid, liquid and vapor phases of water coexist. This occurs at the "triple point" of water, i.e., at the "triple point" values of temperature and pressure. Because the transitions between these three phases are all first order, there is a whole range of combinations of the extensive variables energy and volume for which the system can only be realized by having the coexistence of the ice, liquid and vapor phases. But these three phases coexist only for the triple point values of temperature and pressure, so there is a whole range of combinations of energy and volume that map onto the triple point values of the conjugate intensive variables temperature and pressure with the result that these variables are fine-tuned to the triple point values. In this illustrative analogy, the triple point of water in the phase diagram spanned by the intensive parameters temperature and pressure is analogous to the multiple point. As already stated, the multiple point is the (or a) point in the phase diagram that "touches" the maximum number of phases. In a phase diagram spanned by D intensive parameters (couplings), a generic multiple point can be in contact with up to $D + 1$ phases (in the illustrative example, $D = 2$ and the triple point is in contact with the $D + 1 = 3$ phases ice, liquid and vapour). In a non-generic situation, the multiple point can be in contact with more than $D + 1$ phases (e.g., accidently or due to symmetries).

For ease of illustration, consider now an even simpler system consisting of n_{H_2O} moles of H_2O in which just the ice and liquid phases coexist (at constant pressure). Such a system is unavoidably realized (and the temperature fine-tuned to 0° C $= 273.15^\circ$ K) for *any* value of the energy density $\rho_E = E/V_{n_{H_2O}}$ (E and $V_{n_{H_2O}}$ are respectively the energy and volume of the n_{H_2O} moles of H_2O) in the *finite* interval

$$\frac{n_{H_2O}}{V_{n_{H_2O}}} \int_{0^\circ \text{ K}}^{273^\circ \text{ K}} C_{p,\text{ice}}(T)dT < \rho_E < \frac{n_{H_2O}}{V_{n_{H_2O}}} \left(\int_{0^\circ \text{ K}}^{273^\circ \text{ K}} C_{p,\text{ice}}(T)dT + (\text{molar heat of melting}) \right)$$
($C_{p,\text{ice}}$ is the molar heat capacity of ice at constant pressure (e.g., 1 atm.)). (1)

For any ρ_E in this interval, the system cannot be realized as a single phase but rather only as an equilibriated mixture of ice and liquid water. Even choosing ρ_E at random there is a finite chance of landing in this interval in which case the temperature will be fine-tuned to 273.15° K.

5 The history of our universe as a fine tuner

Consider an analogy between the (3-dimensional) ice-water system with ρ_E in the interval of equation (1) and our 4-dimensional universe with the value of an extensive variable $I_{f_j}[\phi(x)] \stackrel{\text{def}}{=} \int dx^4 \sqrt{g(x)} f_j(\phi(x))$ (with f_j any function of ϕ – see also Section 2 for notation) primordially fixed at a value $I_{\text{fixed } f_j}$ that can only be realized as a combination of two (for the sake of example – really there could be more than two) coexisting phases i.e., two degenerate vacuum states at field values that we denote as ϕ_{us} and ϕ_{other} where we take $\phi_{\text{us}} < \phi_{\text{other}}$. Here we are anticipating the introduction of an effective potential V_{eff} that has relative minima at the field values ϕ_{us} and ϕ_{other}. In 4-space, one generic possibility for having coexistent phases would be to have a phase with ϕ_{us} in an early epoch including, say, the universe as we know it and a phase with ϕ_{other} in a later epoch:

$$I_{\text{fixed } f_j} = f_j(\phi_{\text{us}})(t_{\text{ignit}} - t_{BB})V_3 + f_j(\phi_{\text{other}})(t_{BC} - t_{\text{ignit}})V_3, \tag{2}$$

where t_{ignit} is the "ignition" time (in the future) at which there is a first-order phase transition from the vacuum at ϕ_{us} to the later vacuum at ϕ_{other}. V_3 is the 3-volume of the universe. The value of the "coupling constant" conjugate to $I_{\text{fixed } f_j}$ gets fine-tuned (unavoidably by assumption of the coexistence of the two phases separated by a first order transition) by a mechanism that also depends on a phase that will first be realized in the future (at t_{ignit}). Such a mechanism is non-local. Note, in particular, that the right-hand side of equation (2) depends on t_{ignit}.

In order to formally define a "coupling constant" (intensive quantity) conjugate to some extensive quantity (e.g., $I_{\text{fixed } f_j}$), we introduce non-locality more abstractly. Let us restrict the non-local action $\hat{S}_{\text{nl}} = \hat{S}_{\text{nl}}(\{I_j[\phi(x)]\})$ to being a (also reparameterization invariant) non-local potential V_{nl} that is a function of (not necessarily independent) functionals

$$V_{\text{nl}} \stackrel{\text{def}}{=} V_{\text{nl}}(I_{f_i}[\phi], I_{f_j}[\phi], \ldots).$$

Define now an effective potential V_{eff} such that

$$\frac{\partial V_{\text{eff}}(\phi(x))}{\partial \phi(x)} \stackrel{\text{def}}{=} \frac{\delta V_{\text{nl}}(\{I_{f_j}[\phi]\})}{\delta \phi(x)}\Big|_{\text{near min}} = \sum_i \left(\frac{\partial V_{\text{nl}}(\{I_{f_j}\})}{\partial I_{f_i}} \frac{\delta I_{f_i}[\phi]}{\delta \phi(x)} \right) \Big|_{\text{near min}}$$
$$= \sum_i \frac{\partial V_{nl}(\{I_{f_j}\})}{\partial I_{f_i}}\Big|_{\text{near min}} f_i'(\phi(x)). \tag{3}$$

The subscript "near min" denotes the approximate ground state of the whole universe, up to deviations of $\phi(x)$ from its vacuum value (or vacuum values for a multi-phase vacuum) by any amount in relatively small space-time regions. The solution to equation (3) is

$$V_{\rm eff}(\phi) = \sum_i \frac{\partial V_{\rm nl}(\{I_{f_j}\})}{\partial I_{f_i}} f_i(\phi). \tag{4}$$

We can identify the $\frac{\partial V_{\rm nl}(\{I_{f_j}\})}{\partial I_{f_i}}$ as intensive quantities conjugate to the I_{f_i}.

Consider now the effective potential (4) in the special case that $V_{\rm nl}(\{I_{f_j}\}) = V_{\rm nl}(I_2, I_4) \stackrel{\rm def}{=} V_{\rm nl}(\int d^4x\sqrt{g(x)}\phi^2(x), \int d^4y\sqrt{g(y)}\phi^4(y))$ in which case, (4) becomes

$$V_{\rm eff} = \frac{\partial V_{\rm nl}(I_2, I_4)}{\partial I_2}\phi^2(x) + \frac{\partial V_{\rm nl}(I_2, I_4)}{\partial I_4}\phi^4(x) \stackrel{\rm def}{=} \frac{1}{2}m^2_{\rm Higgs}\phi^2(x) + \frac{1}{4}\lambda\phi^4(x), \tag{5}$$

where the right-hand side of this equation, which also defines the (intensive) couplings $m^2_{\rm Higgs}$ and λ, is recognised as a prototype scalar potential at the tree level. Of course, the form of $V_{\rm nl}$ is, at least *a priori*, completely unknown to us, so – for example – the coupling constant $m^2_{\rm Higgs}$ cannot be calculated from equation (5). The potential of equation (5) with $m^2_{\rm Higgs} < 0$ has an asymmetric minimum – at, say, the value $\phi_{\rm us}$ resulting in spontaneous symmetry breakdown in the familiar way. This is just standard physics (without non-locality).

Actually, we want to consider the potential $V_{\rm eff}$ having the two relative minima $\phi_{\rm us}$ and $\phi_{\rm other}$ – both at nonvanishing values of ϕ – alluded to at the beginning of this section. The second minimum comes about at a value $\phi_{\rm other} > \phi_{\rm us}$ when radiative corrections to (5) are taken into account and the top quark mass is not too large [6, 7, 3]. Which of these vacua – the one at $\phi_{\rm us}$ or $\phi_{\rm other}$ – would be the stable one in this two-minima Standard Model effective Higgs field potential, depends on the value of $m^2_{\rm Higgs}$. Since I_2 and I_4 are functions of $t_{\rm ignit}$ (as seen from equation (2) with $f_j = \phi^2$ or ϕ^4), $m^2_{\rm Higgs} \stackrel{\rm def}{=} \frac{\partial V_{\rm nl}(\{I_2, I_4\})}{\partial I_2}$ is also a function of $t_{\rm ignit}$.

Let us first use "normal physics" to see how the relative depths of the two minima of the double well are related to $m^2_{\rm Higgs}$ and to $t_{\rm ignit}$. It can be deduced from [7] that a large negative value of $m^2_{\rm Higgs}$ corresponds to the relative minimum $V_{\rm eff}(\phi_{\rm other})$ being deeper than $V_{\rm eff}(\phi_{\rm us})$ (in which by assumption the Universe starts off following Big Bang) than for smaller negative values of $m^2_{\rm Higgs}$ (see Fig. 1). It can also be argued quite plausibly that a minimum in $V_{\rm eff}$ at $\phi_{\rm other}$ much deeper than that at $\phi_{\rm us}$ would correspond to an early (small) $t_{\rm ignit}$ inasmuch as the "false" vacuum at ϕ_{us} would be very unstable. However, as the value of the potential at $\phi_{\rm other}$ approaches that at $\phi_{\rm us}$, $t_{\rm ignit}$ becomes longer and longer, and approaches infinity as the values of $V_{\rm eff}$ at $\phi_{\rm us}$ and $\phi_{\rm other}$ become the same. The development of the double well potential and $m^2_{\rm Higgs}$ as a function of $t_{\rm ignit}$ is illustrated in Fig. 1. Note that the larger the difference $|V_{\rm eff}(\phi_{\rm other}) - V_{\rm eff}(\phi_{\rm us})|$ the more the realization of, say, $I_{\rm fixed\,2}$ will in general depend on $t_{\rm ignit}$. If $V_{\rm eff}(\phi_{\rm us}) = V_{\rm eff}(\phi_{\rm other})$, $t_{\rm ignit}$ plays no role in realizing e.g. $I_{\rm fixed\,2}$, and the value of $m^2_{\rm Higgs}$ becomes independent of $t_{\rm ignit}$.

6 Avoiding paradoxes arising from non-locality

In general, the presence of non-locality leads to paradoxes. While the form of the non-local action (or potential $V_{\rm nl}$ in this discussion) is unknown to us, we make the 4 generically representative guesses portrayed as the 4 non-locality curves in Fig. 1. In particular, non-locality curves having a negative slope as a function of $t_{\rm ignit}$ lead to paradoxes in the following manner. Consider the non-locality curve in Fig. 1 drawn with bold line that is redrawn in a rotated position in Fig. 2. Let us make the assumption that $t_{\rm ignit}$ is large and see that this leads to a contradiction. Assuming that $t_{\rm ignit}$ is large, it is seen from the non-locality function in Fig. 2 (call it

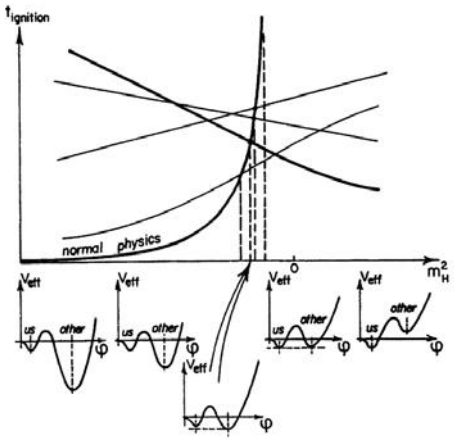

Figure 1. The development of the double well potential and $m_{\rm Higgs}$ as a function of $t_{\rm ignit}$. Note that all the more or less randomly drawn non-locality curves intersect the "normal physics" curve near where the vacua are degenerate (i.e., the MPP solution).

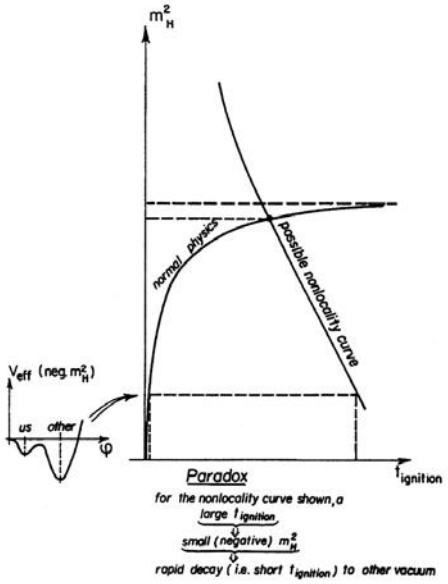

Figure 2. Many non-locality curves could lead to paradoxes similar to the "matricide" paradox. Such paradoxes are avoided if the value of $m_{\rm Higgs}$ is fine-tuned to the multiple point critical value. This corresponds to the intersection of the "normal physics" curve with the "possible non-locality" curve.

$m^2_{\rm Higgs\ nl}(t_{\rm ignit})$ to distinguish it from the "normal physics" $m^2_{\rm Higgs}(t_{\rm ignit})$) that this implies that the "normal physics" $m^2_{\rm Higgs}$ has a large negative value. But a large negative value of $m^2_{\rm Higgs}$ corresponds in "normal physics" to a (false) vacuum at $\phi_{\rm us}$ that is very unstable and therefore to a very short $t_{\rm ignit}$ corresponding to a rapid decay to the stable vacuum at $\phi_{\rm other}$. So the paradox appears: the assumption of a *large* $t_{\rm ignit}$ implies a *small* $t_{\rm ignit}$. This happens because in general $m^2_{\rm Higgs}(t_{\rm ignit}) \neq m^2_{\rm Higgs\ nl}(t_{\rm ignit})$ and is akin to the "matricide" paradox encountered for example when dealing with "time machines". It is well-known [8–10] that Nature avoids such paradoxes by choosing a very clever solution in situations where these paradoxes lure.

In the case of the paradoxes that can come about due to non-locality of the type considered here, a clever solution that avoids paradoxes is available to Nature in the form of the Multiple Point Principle (MPP). The MPP solution corresponds to the intersection of the "normal physics" curve and the "non-locality curve" in Fig. 2. because here the vacua at $\phi_{\rm us}$ and $\phi_{\rm other}$ are (essentially) degenerate. But at this intersection point, $m^2_{\rm Higgs}(t_{\rm ignit}) = m^2_{\rm Higgs\ nl}(t_{\rm ignit})$ so the paradox is avoided. So the paradox is avoided at the multiple point. But at the multiple point, an intensive parameter has its value fine-tuned for a wide range of values of the conjugate extensive quantity. Fine-tuning can therefore be understood as a consequence of Nature's way of avoiding paradoxes that can come about due to non-locality.

It should be pointed out that the paradox-free solution corresponding to the intersection of the two curves in Fig. 2 occurs for a value of $m^2_{\rm Higgs}$ corresponding to "our" vacuum at $\phi_{\rm us}$ being very slightly unstable. The value of $m^2_{\rm Higgs}$ corresponding to the vacua at $\phi_{\rm us}$ and $\phi_{\rm other}$ being (precisely) degenerate is slightly less negative than that corresponding to the multiple point value of $m^2_{\rm Higgs}$ at the intersection of the curves. Note that the multiple point value of $m^2_{\rm Higgs}$ is very insensitive to which "guess" we use for the non-local action. Indeed all the "non-locality" curves in Fig. 1 intersect the "normal physics" curve at values of $m^2_{\rm Higgs}$ that are tightly nested together. The reason for this is that $m^2_{\rm Higgs}$ is a very slowly varying function of $t_{\rm ignit}$ as

$m^2_{\rm Higgs}(t_{\rm ignit})$ approaches the value corresponding to degenerate vacua. The more nearly parallel the "normal physics" and the "non-locality" curves at the point of intersection, the smaller are the (paradoxical) effects of non-locality. For a point of intersection at values of $t_{\rm ignit}$ sufficiently large that (the "normal physics") $m^2_{\rm Higgs}(t_{\rm ignit}) \approx m^2_{\rm Higgs}(\infty)$, the non-locality effects disappear as the curves become parallel since both curves become independent of $t_{\rm ignit}$. If the curves were parallel, there would also be the possibility that these do not intersect, in which case there would be no "miraculous solution" that could avoid the paradoxes imbued in having non-locality.

If the interval $|\phi^2_{\rm other}–\phi^2_{\rm us}|$ is large (e.g. of the order of the largest physically conceivable scale (Planck?) if tuning is to be maximally effective) and if $I_{\rm fixed\,2}$ falls not too close to the ends of this interval, then $t_{\rm ignit}$ will be something of the order of half the life of the universe. Actually, the approximate degeneracy of the vacua $V_{\rm eff}(\phi_{\rm us}) \approx V_{\rm eff}(\phi_{\rm other})$ may be characteristic of the temperature of the post-Big Bang universe in the present epoch and *not* characteristic of the high temperature that prevailed immediately following the Big Bang. At high temperatures, the free energy is considerably smaller than the total energy if the entropy is large enough. A phase with a large number of light particles – for example a Coulomb-like vacuum such as the "us" phase in which we live – could very plausibly be so strongly favoured at high temperatures that other phases – for example the "other" vacuum – simply disappeared at the high temperature of the universe immediately following the Big Bang.

If this were to have depleted the universe of the phase having $\phi_{\rm other}$ at high temperatures, it would indeed be difficult to re-establish it in a lower temperature universe even if the vacuum at $\phi_{\rm us}$ were to be only meta-stable and the vacuum at $\phi_{\rm other}$ were the true vacuum at the lower temperature. Such an exchange of the true vacuum is indeed a possibility in going to lower temperatures inasmuch as the difference between the total energy and the free energy decreases in going to lower temperatures. Accordingly, this difference becomes less effective in favoring a Coulomb-like phase at the expense of a phase with heavier particles.

At this point we point out that when we say the "vacuum at $\phi_{\rm us}$" and "vacuum at $\phi_{\rm other}$" we are thinking of the approximation $\phi = \phi_{\rm us}$ and $\phi = \phi_{\rm other}$ almost everywhere, and at all times in respectively the early and late epochs of the universe in our discussion. More correctly, we should talk about vacuum densities $\langle\phi(x^0,\vec{x})\rangle_{\rm us}$ and $\langle\phi(x^0,\vec{x})\rangle_{\rm other}$ where

$$\langle\phi(x^0,\vec{x})\rangle_{\rm us} \stackrel{\rm def}{=} \frac{1}{V_{\rm us}}\int_{t_{BB}}^{t_{\rm ignit}} dx^0 \int d^3\vec{x}\sqrt{g(x)}\phi(x^0,\vec{x}),$$

where $V_{\rm us}$ denotes the the 4-volume of the universe in the first epoch. $\langle\phi(x^0,\vec{x})\rangle_{\rm other}$ is defined analogously. The more correct $\langle\phi(x^0,\vec{x})\rangle_{\rm us}$ is mentioned here so as not to confuse the reader when we talk about changes in $V_{\rm eff}(\phi_{\rm us}(x^0,\vec{x}))$ as the universe cools following Big Bang.

Recall now that the value of say of $I_{\rm fixed\,2}$ can easily (i.e. as a generic possibility) assume a value that requires that the universe to be in the "phase" with $\langle\phi(x^0,\vec{x})\rangle_{\rm other}$ during a sizeable part of its life, if the universe is to have multiple point parameters in the course of its evolution (as required for avoiding the paradoxes that accompany non-locality). How can Nature overcome the energy barrier that must be surmounted in order to bring about the decay of the slightly unstable (false) vacuum with $\langle\phi(x^0,\vec{x})\rangle_{\rm us}$ to the vacuum with $\langle\phi(x^0,\vec{x})\rangle_{\rm other}$? Even producing just a tiny "seed" of the "true" vacuum having $\langle\phi(x^0,\vec{x})\rangle_{\rm other}$ would be very difficult. What miraculously clever means can Nature devise so as to avoid deviations from a multiply critical evolution of the universe? One ingenious master plan that Nature may have implemented is the creation of life with the express "purpose" of evolving some (super intelligent?) physicists that could ignite a "vacuum bomb" by first creating in some very expensive accelerator the required "seed" of the "correct" vacuum having $\langle\phi(x^0,\vec{x})\rangle_{\rm other}$ that subsequently would engulf the universe in a (for us) cataclysmic transition to the "other" phase thereby permitting the continued evolution of a "paradox-free" universe!

7 Conclusion

We attempt to justify the assertion that fine-tuning in Nature seems to imply a fundamental form of non-local interaction. This could be manifested in a phenomenologically acceptable form as everywhere in space-time identical interactions between any pair of space-time points. This would be implemented by requiring the non-local action to be diffeomorphism invariant.

Next we put forth our multiple point principle which states that coupling parameters in the Standard Model tend to assume values that correspond to the values of action parameters lying at the junction of a maximum number of regulator induced phases (e.g., so-called "lattice artifact phases") separated from one another in action parameter space by first order transitions. The action which of course is defined on a gauge group (e.g., the non-simple SM gauge group) governs fluctuation patterns along the various subgroup combinations (K, H) with $H \lhd K \subseteq G$ that characterize the phases that come together at the multiple point. We then consider extensive quantities that are functions of functionals $I_{f_j}[\phi(x)]$ that are essentially Feymann path histories of the Universe for functions $f_j(\phi)$ of the fields $\phi(x)$ and derivatives of these fields. We then think of the generic situation in which these extensive quantities can happen to be fixed at values that require the universe to be realized as two or more coexisting phases. We draw on the analogy to the forced coexistence of ice and liquid water that occurs for a whole range of possible total energies because of the finite heat of melting (first order phase transition). With our multiple point principle, the intensive quantities (couplings) conjugate to extensive quantities fixed in this way become fine-tuned in a manner analogous to the fine tuning of temperature to 0° C when the total energy of a system of H_2O can only be realized as coexisting ice and liquid phases.

One generic way of having coexisting phases in a quantum field theory in 3+1 dimensions would be to have different phases in different epochs of the lifetime of the Universe with phase transitions occurring at various times in the course of the lifetime of the Universe. If the transitions were first order, one would have fine-tuning of (intensive) couplings conjugate to extensive quantity values that can only be realized by having coexisting (i.e., more than one) phases. But such a fine-tuning would involve non-locality: the fine-tuned values of coupling constants would depend on future phase transitions into phases that do not even exist at the time such couplings are fine-tuned.

Even non-locality of this sort (i.e., non-locally manifested as a diffeomorphism invariant non-local action) can lead to paradoxes of the "matricide paradox" type. We argue that such paradoxes are avoided when Nature chooses the multiple point principle solution to the problem of fine-tuning.

The work is devoted to the generalization of the Dirac equation for a flat locally anisotropic, i.e. Finslerian space-time. At first we reproduce the corresponding metric and a group of the generalized Lorentz transformations, which has the meaning of the relativistic symmetry group of such event space. Next, proceeding from the requirement of the generalized Lorentz invariance we find a generalized Dirac equation in its explicit form. An exact solution of the nonlinear generalized Dirac equation is also presented.

1 Introduction

In spite of the impressive successes of the unified gauge theory of strong, weak and electromagnetic interactions, known as the Standard Model, one cannot a priori rule out the possibility that Lorentz symmetry underlying the theory is an approximate symmetry of nature. This implies that at the energies already attainable today empirical evidence may be obtained in favor of violation of Lorentz symmetry. At the same time it is obvious that such effects might manifest themselves only as strongly suppressed effects of Planck-scale physics.

Theoretical speculations about a possible violation of Lorentz symmetry continue for more than forty years and they are briefly outlined in [1]. Nevertheless we note here that, along with the spontaneous breaking [2], one of the first and, as it appeared subsequently, fruitful ideas relating to a possible violation of Lorentz symmetry was the idea [3] according to which the metric of event space differs from Minkowski metric and the physically equivalent inertial reference frames are linked by some transformations which differ from Lorentz ones. In [4] such transformations were called generalized Lorentz transformations. Note also that the idea about the existence of generalized Lorentz transformations was suggested in connection with the situation in the physics of ultra-high energy cosmic rays, namely, with the absence of the Greisen–Zatsepin–Kuz'min effect (the so-called GZK cutoff) predicted [5, 6] on the basis of conventional relativistic theory. The absence of the GZK cutoff has yet not been explained convincingly and still remains the main empirical fact which indirectly speaks in favor of violation of Lorentz symmetry.

Interest in the problem of violation of Lorentz and CPT symmetries has revived in recent years [7] in connection with the construction of a phenomenological theory reffered to as the Standard-Model Extension [8].

In the present work, which is in essence devoted to the same problem, we proceed from the assumption [9] that phase transitions with breaking of gauge symmetries should be accompanied by phase transitions in the geometric structure of space-time.

Our study is based on the fact [10] that the Lorentz symmetry is not the only possible realization of the relativistic symmetry. Another admissible realization of the relativistic symmetry is obtained with the aid of nonunimodular matrices belonging to a group of the generalized Lorentz

transformations. In contrast to the conventional Lorentz transformations, the generalized ones conformally modify Minkowski metric but leave invariant the corresponding Finslerian metric which describes a flat locally anisotropic space-time. Thus, from the formal point of view the locally anisotropic space-time appeares as the necessary consequence of the existence of a group of the generalized Lorentz transformations. As for the physical nature of the anisotropy, there are some reasons to suppose that a fermion-antifermion condensate, which may arise [11] (instead of elementary Higgs condensate) in the spontaneous breaking of initial gauge symmetries, turns out to be anisotropic and its anisotropy determines the local anisotropy of event space. Obviously, verification of this hypothesis is far from being trivial. Therefore the opening investigations in this direction, as presented here, are aimed at the most fundamental problem, namely, at the generalization of the Dirac equation for the locally anisotropic space-time.

2 Flat locally anisotropic space-time as a geometric invariant of a group of the generalized Lorentz transformations

Consider the metric [4] of a flat locally anisotropic space-time

$$ds^2 = \left[\frac{(dx_0 - \boldsymbol{\nu} d\boldsymbol{x})^2}{dx_0^2 - d\boldsymbol{x}^2}\right]^r \left(dx_0^2 - d\boldsymbol{x}^2\right). \tag{1}$$

Being not a quadratic form but a homogeneous function of the coordinate differentials of degree two, this metric falls within the category of Finsler metrics [12]. It depends on two constant parameters r and $\boldsymbol{\nu}$, in which case the unit vector $\boldsymbol{\nu}$ indicates a preferred direction in 3D space while r determines the magnitude of space anisotropy, characterizing the degree of deviation of the metric (1) from the Minkowski metric. Thus the anisotropic event space (1) is the generalization of the isotropic Minkowski space of conventional special relativity theory.

The 3-parameter noncompact group of the generalized Lorentz transformations, which leave the metric (1) invariant, appears as

$$x'^i = D(\boldsymbol{v}, \boldsymbol{\nu}) R^i_j(\boldsymbol{v}, \boldsymbol{\nu}) L^j_k(\boldsymbol{v}) x^k, \tag{2}$$

where $\boldsymbol{v}$ denotes the velocities of moving (primed) inertial reference frames; the matrices $L^j_k(\boldsymbol{v})$ represent the ordinary Lorentz boosts; the matrices $R^i_j(\boldsymbol{v}, \boldsymbol{\nu})$ represent additional rotations of the spatial axes of the moving frames around the vectors $[\boldsymbol{v}\,\boldsymbol{\nu}]$ through the angles

$$\varphi = \arccos\left\{1 - \frac{\left(1 - \sqrt{1 - \boldsymbol{v}^2/c^2}\right)[\boldsymbol{v}\boldsymbol{\nu}]^2}{(1 - \boldsymbol{v}\boldsymbol{\nu}/c)\boldsymbol{v}^2}\right\}$$

of relativistic aberration of $\boldsymbol{\nu}$; and the diagonal matrices

$$D(\boldsymbol{v}, \boldsymbol{\nu}) = \left(\frac{1 - \boldsymbol{v}\boldsymbol{\nu}/c}{\sqrt{1 - \boldsymbol{v}^2/c^2}}\right)^r I,$$

the additional dilatational transformations of the event coordinates. The structure of the transformations (2) ensures the fact that in spite of a new geometry of event space the 3-velocity space remains Lobachevski space.

With the inclusion of the 1-parameter group of rotations about $\boldsymbol{\nu}$ and of the 4-parameter group of translations the inhomogeneous isometry group of the Finslerian event space (1) turns out to have eight parameters. If the third spatial axis is chosen along $\boldsymbol{\nu}$, then its generators can

be written as

$$
\begin{aligned}
X_1 &= -\left(x^1 p_0 + x^0 p_1\right) - \left(x^1 p_3 - x^3 p_1\right), \\
X_2 &= -\left(x^2 p_0 + x^0 p_2\right) + \left(x^3 p_2 - x^2 p_3\right), \\
X_3 &= -r x^i p_i - \left(x^3 p_0 + x^0 p_3\right), \\
R_3 &= x^2 p_1 - x^1 p_2; \qquad p_i = \partial/\partial x^i.
\end{aligned}
$$

These generators satisfy the commutation relations

$$
\begin{aligned}
&[X_1 X_2] = 0, && [R_3 X_3] = 0, \\
&[X_3 X_1] = X_1, && [R_3 X_1] = X_2, \\
&[X_3 X_2] = X_2, && [R_3 X_2] = -X_1; \\
&[p_i p_j] = 0; \\
&[X_1 p_0] = p_1, && [X_2 p_0] = p_2, && [X_3 p_0] = r p_0 + p_3, && [R_3 p_0] = 0, \\
&[X_1 p_1] = p_0 + p_3, && [X_2 p_1] = 0, && [X_3 p_1] = r p_1, && [R_3 p_1] = p_2, \\
&[X_1 p_2] = 0, && [X_2 p_2] = p_0 + p_3, && [X_3 p_2] = r p_2, && [R_3 p_2] = -p_1, \\
&[X_1 p_3] = -p_1, && [X_2 p_3] = -p_2, && [X_3 p_3] = r p_3 + p_0, && [R_3 p_3] = 0.
\end{aligned}
$$

As one can see the 8-parameter inhomogeneous isometry group of the space-time (1) is a subgroup of the 11-parameter extended Poincaré (similitude) group [13] whereas the homogeneous one is isomorphic to the corresponding 4-parameter subgroup (with the generators X_1, X_2, $X_3|_{r=0}$, R_3) of the homogeneous Lorentz group. It is shown in [14] that the 6-parameter homogeneous Lorentz group has no 5-parameter subgroup while the 4-parameter subgroup is unique (up to isomorphisms). Thus, the transition from Minkowski space to the Finslerian event space (1) implies a minimum of symmetry-breaking of the Lorentz symmetry. However the relativistic symmetry is maintained in the form of the generalized Lorentz symmetry.

3 Covariant formulation of the theory. Generalized relativistic point mechanics

Because of nonunimodularity of the matrices $\mathcal{L}^i_k = DR^i_j L^j_k$ representing the generalized Lorentz transformations (2), the transformational properties of some geometric entities turn out to be changed as compared with conventional special relativity theory. For instance, a 4-volume element $dx^0 d^3x$ is no longer invariant but is a scalar density of weight -1, i.e., it transforms as follows: $dx'^0 d^3x' = J^{-1} dx^0 d^3x$, where J is the Jacobian, $J = |\partial x^k/\partial x'^j| = |\mathcal{L}^{-1}{}^k_j| = D^{-4}$. Similarly, matrices η_{ik} and η^{ik} having the identical forms $\eta_{ik} = \mathrm{diag}\,(1,-1,-1,-1)$ and $\eta^{ik} = \mathrm{diag}\,(1,-1,-1,-1)$ in all frames of reference related by the transformations (2) are no longer invariant tensors but are, respectively, a covariant tensor density of weight $-1/2$ and a contravariant tensor density of weight $1/2$. This statement signifies that $\eta'_{ik} = J^{-1/2}\mathcal{L}^{-1}{}^l_i \mathcal{L}^{-1}{}^m_k \eta_{lm} = \eta_{ik}$ and $\eta'^{ik} = J^{1/2}\mathcal{L}^i_l \mathcal{L}^k_m \eta^{lm} = \eta^{ik}$. Then it is clear that $\eta_{ik}\eta^{kl} = \delta^l_i$ is a unit tensor. Later on we shall be using η_{ik} and η^{ik} to lower and raise indices. The process, however, will be accompanied by a change in weight. We shall be also in need of an entity ν^i which indicates a preferred direction in 4D space-time and whose components have the same values, $\{\nu^0 = 1, \boldsymbol{\nu}\}$, in all frames of reference related by the transformations (2). It is easy to verify that $\nu'^i = J^{(1+r)/(4r)}\mathcal{L}^i_k \nu^k = \nu^i$, i.e., that ν^i is a contravariant vector density of weight $(1+r)/(4r)$, in which case $\nu_i \nu^i = 0$ is an invariant equation.

Using the ν^i and η_{ik} one can represent the metric (1) as an explicit invariant of the transformations (2): $ds^2 = \left[(\nu_i dx^i)^2/dx_j dx^j\right]^r dx_k dx^k$. With the aid of this expression we arrive at the relativistically invariant action for a free particle in the flat anisotropic space. The action and

its variation appear as

$$S = -m\int_a^b ds, \qquad \delta S = -\int_a^b p_i\, d\delta x^i.$$

Hereafter we put $c = \hbar = 1$. The principle of least action under the condition $(\delta x^i)|_a = (\delta x^i)|_b = 0$ leads to $p_i = \text{const}$, i.e., to rectilinear inertial motion. And if one varies the coordinates of point b under the condition $p_i = \text{const}$, then $p_i = -\partial S/\partial x^i$, i.e., p_i is a canonical 4-momentum. Since η^{ik} is a contravariant tensor density of weight 1/2 and since p_k is a covariant vector it is clear that the 4-momentum $p^i = (p^0, \boldsymbol{p}) = \eta^{ik}p_k$ is transformed as a contravariant vector density of 1/2, i.e.,

$$p'^i = J^{1/2}\mathcal{L}^i_k p^k = D^{-1}R^i_l L^l_k p^k. \tag{3}$$

Thus we have arrived at the generalized Lorentz transformations for 4-momenta. Note that the dilatational transformations of p^i are inverse to those of x^i (cf. (2)). In an explicit form

$$p^i = m\left(\frac{\nu_l dx^l}{\sqrt{dx_j dx^j}}\right)^r \left((1-r)\frac{dx^i}{\sqrt{dx_a dx^a}} + r\frac{\nu^i\sqrt{dx_b dx^b}}{\nu_n dx^n}\right). \tag{4}$$

Since the direction of p^i is not aligned with the direction of dx^i we introduce (apart from p^i) the so-called kinematic 4-momentum k^i which has the same transformational properties as p^i.

$$k^i = m(1-r)\frac{dx^i}{\sqrt{dx_n dx^n}}\left(\frac{\nu_l dx^l}{\sqrt{dx_j dx^j}}\right)^r. \tag{5}$$

Taking into account the equation $\nu_i\nu^i = 0$ we obtain the following relations

$$p^i = k^i + \frac{rk_l k^l}{(1-r)k_n\nu^n}\nu^i, \qquad k^i = p^i - \frac{rp_l p^l}{(1+r)p_n\nu^n}\nu^i. \tag{6}$$

As for the 3-velocity of a particle, it is determined by the formula $\boldsymbol{v} = \boldsymbol{k}/k^0$.

The components of canonical 4-momenta satisfy the mass shell equation

$$\left[(\nu_i p^i)^2/p_j p^j\right]^{-r} p_a p^a = m^2(1-r)^{(1-r)}(1+r)^{(1+r)}. \tag{7}$$

This equation is an invariant of the transformations (3). The same mass shell but in a space of kinematic 4-momenta is described by the equation

$$\left[(\nu_i k^i)^2/k_j k^j\right]^{-r} k_a k^a = m^2(1-r)^2. \tag{8}$$

The latter two equations lead us to the important conclusion, namely, that the motion of free massless particles in anisotropic space is similar to their motion in isotropic space, i.e., massless particles do not perceive the space anisotropy whereas the motion of massive particles is analogous to that of quasiparticles in a crystalline medium.
