Introduction

The Standard Model is INCOMPLETE.

- Higgs boson remains undiscovered

Leaves interesting unanswered questions:

How is electro weak symmetry broken?

How do fermions get their masses?

How do the W^\pm and Z^0 get their masses?

How is unitarity preserved in $WW \rightarrow WW$
and $WZ \rightarrow WZ$ scattering?

Leads to interesting models:

Higgs-containing models

Higgs \rightarrow SUSY Higgs \rightarrow Flat Higgs hep-ph/0311349 Hanke et.al.
(1964) (1975) \rightarrow Little Higgs hep-ph/0206021 Arkani-Hamed et.al.
 \rightarrow Little SUSY Higgs hep-ph/0409142 Kitano, Takabayashi
 \rightarrow Phat Higgs hep-ph/0708329 A.S., Acharya
 \rightarrow Many others V. Dimopoulos

Technicolor models (strongly-coupled Higgsless)

Gildener & Weinberg (1970)

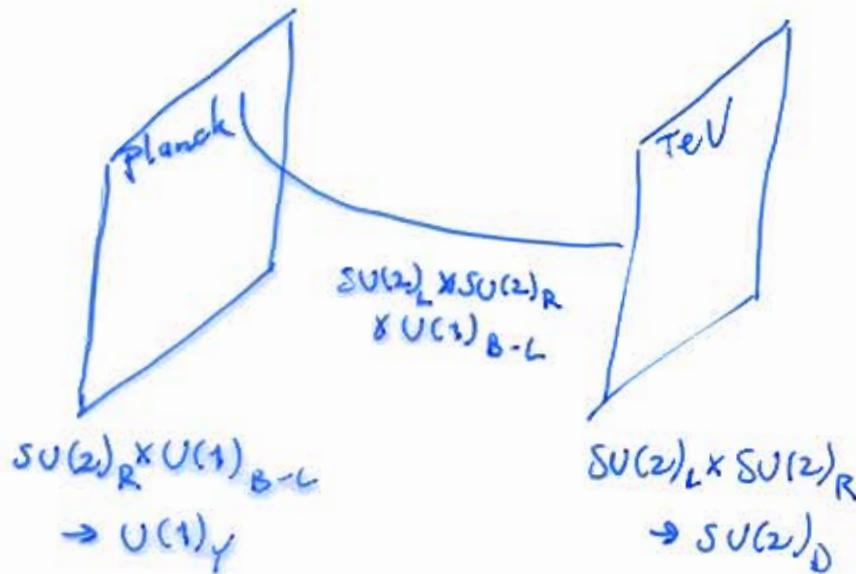

Dine, Srednicki, Wilen (1979) + many others
Still current, see Cuiyi + Okui hep-ph/0409274
and more!

'Higgsless' models (weakly coupled Higgsless)

Csaki et. al. hep-ph/0305237
hep-ph/0308038

Introduction to Higgsless

- Electroweak symmetry is broken by higher-dimensional boundary conditions, not a Higgs mechanism

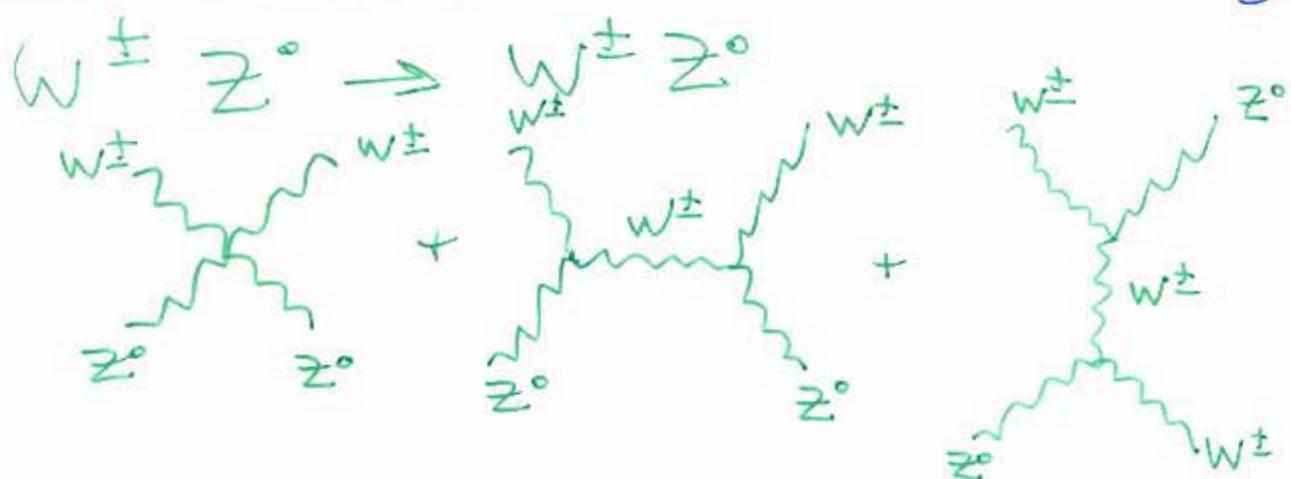

- Usual SM value of $\frac{M_W}{M_Z}$ guaranteed by $SU(2)_R$ bulk symmetry (like custodial $SU(2)$) in SM (Sikivie et.al 1979), Agashe, et.al. 2003)
- Fermion mass generation and placement is very model-dependent, we won't deal with it here.
- No Higgs, so unitarity is restored by KK gauge bosons.

Massive Gauge Boson Scattering and Unitarity

- EWSB \rightarrow massive W^\pm and Z^0
 - \rightarrow extra polarizations for W^\pm and Z^0
 - \rightarrow interesting behavior for gauge boson scattering
(we'll focus on $WZ \rightarrow WZ$)

In the Standard Model without a Higgs,

$$\begin{aligned}
 M_{\substack{\text{SM-H} \\ : (M_w^2 M_z^2)}}^{W^\pm Z W^\pm Z} &= \left(g_{WWZz} - g_{WWzz}^2 \right) / \left(c^2 - 6c - 3 \right) E^4 \\
 &+ \left(c^2 - 3c - 2 \right) M_z^2 E^2 - \left(c^2 - 9c - 4 \right) M_w^2 E^2 \\
 &+ g_{WWzz}^2 \frac{M_z^4 (1-c)}{2 M_w^2} E^2 + \mathcal{O}(E^0)
 \end{aligned}$$

c: cosine of scattering angle

E: energy of incoming W in c.m. frame

At high energy, this leads to violations of unitarity (probability > 1)!

That doesn't make any sense, so something HAS to fix it:

- underlying gauge theory forces

$$g_{WWZ} = g_{WW}^2 \quad (\text{in S.M.})$$

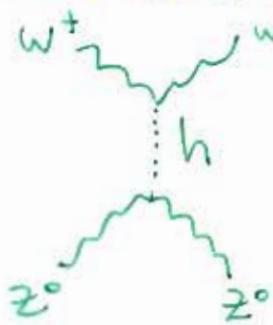

That helps!

$$\frac{\mathcal{M}_{SM-H}^{W^\pm Z W^\pm Z}}{\sqrt{M_W^2 M_Z^2}} = g_{WW}^2 \frac{M_Z^4 (1 - c)}{2 M_W^2} E^2 + \mathcal{O}(E^0)$$

Still NOT unitary (unitary: $\mathcal{M} \sim \text{const.}$)

New particles? (like the Higgs)

In the Standard Model, there is the Higgs:

This restores unitarity so that

$$\frac{M_{SM}}{\sqrt{(M_w^2 M_Z^2)}} \stackrel{w^\pm w^\pm}{=} \mathcal{O}(E^0)$$

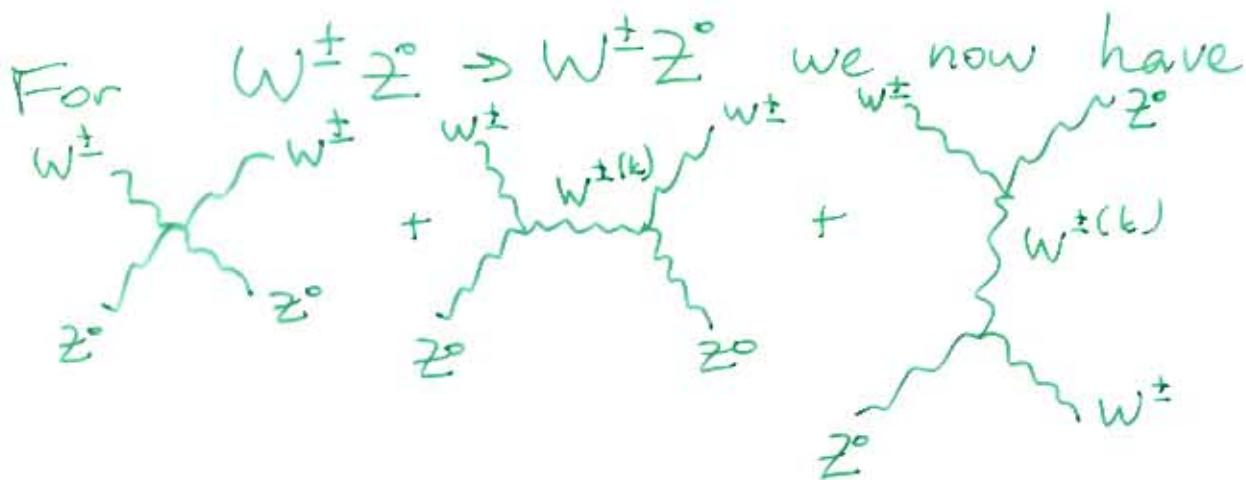

If the Higgs is absent, unitarity appears to be violated at a scale:

$$\Lambda \sim 4\pi \frac{M_W}{g} \sim 1.8 \text{ TeV}$$

If new particles (or something else?) don't appear before this scale, W^\pm , Z become strongly coupled.

What happens in these new 'Higgsless' models of EWSB?

- no Higgs, but we've got KK excitation of the W^\pm and Z and γ

For each $W^{\pm(k\pm 0)}$ we get the additional contribution

$$\frac{\Delta M_k^{W^\pm Z W^\pm Z}}{i(M_W^2 M_Z^2)} = - (g_{W^\pm Z W^\pm}^{(k)})^2 \left[(c^2 - 6c - 3) E^4 + (c^2 - 2c - 3) M_Z^2 E^2 - (c^2 - 10c - 3) M_W^2 E^2 + (1-c) \frac{3(M_{W(k)})^4 - (M_W^2 - M_Z^2)^2}{2(M_{W(k)})^2} E^2 \right] + \mathcal{O}(E^0)$$

So in order for the $W^{\pm(k\neq 0)}$'s to restore unitarity in $W^\pm Z^0 \rightarrow W^\pm Z^0$, the following sum rules must be obeyed:

$$g_{WWZ^2} = g_{WWZ}^2 + \sum_{i=1,\dots}^{\infty} (g_{W^\pm W^{(i)}}^{(i)})^2$$

$$2(g_{WWZ} - g_{WWZ}) (M_W^2 + M_Z^2) + g_{WWZ}^2 \frac{M_Z^4}{M_W^2}$$

$$= \sum_{i=1,\dots}^{\infty} (g_{W^\pm W^{(i)}}^{(i)})^2 \left[3(M_{W^{(i)}})^2 - \frac{(M_Z^2 - M_W^2)^2}{(M_{W^{(i)}})^2} \right]$$

These are satisfied exactly in 5D theories if the whole KK tower is taken into account

(required by gauge invariance and locality of the underlying theory)

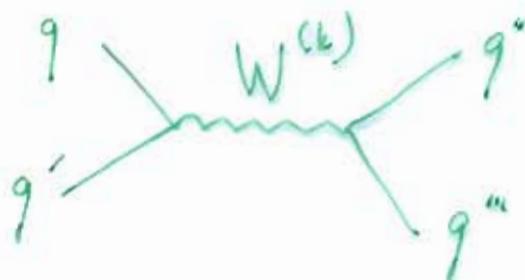

Eventually the increasing number of inelastic channels do spoil unitarity but this is delayed until

$$\Lambda_{NDA} \sim \frac{3\pi^4}{g^2} \frac{M_W^2}{M_{W^{(1)}}} \quad (\text{O}(5-10 \text{TeV}))$$

Testing the Mechanism of EWSB and Unitarity Restoration (@ the LHC)

How can we discover (or rule out) the 'Higgsless' models at the LHC?

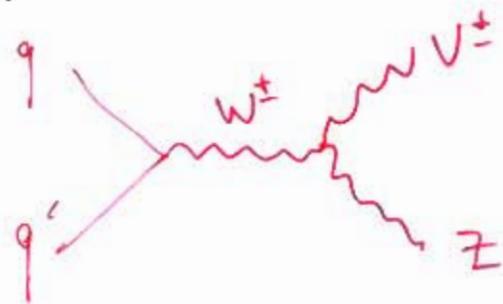

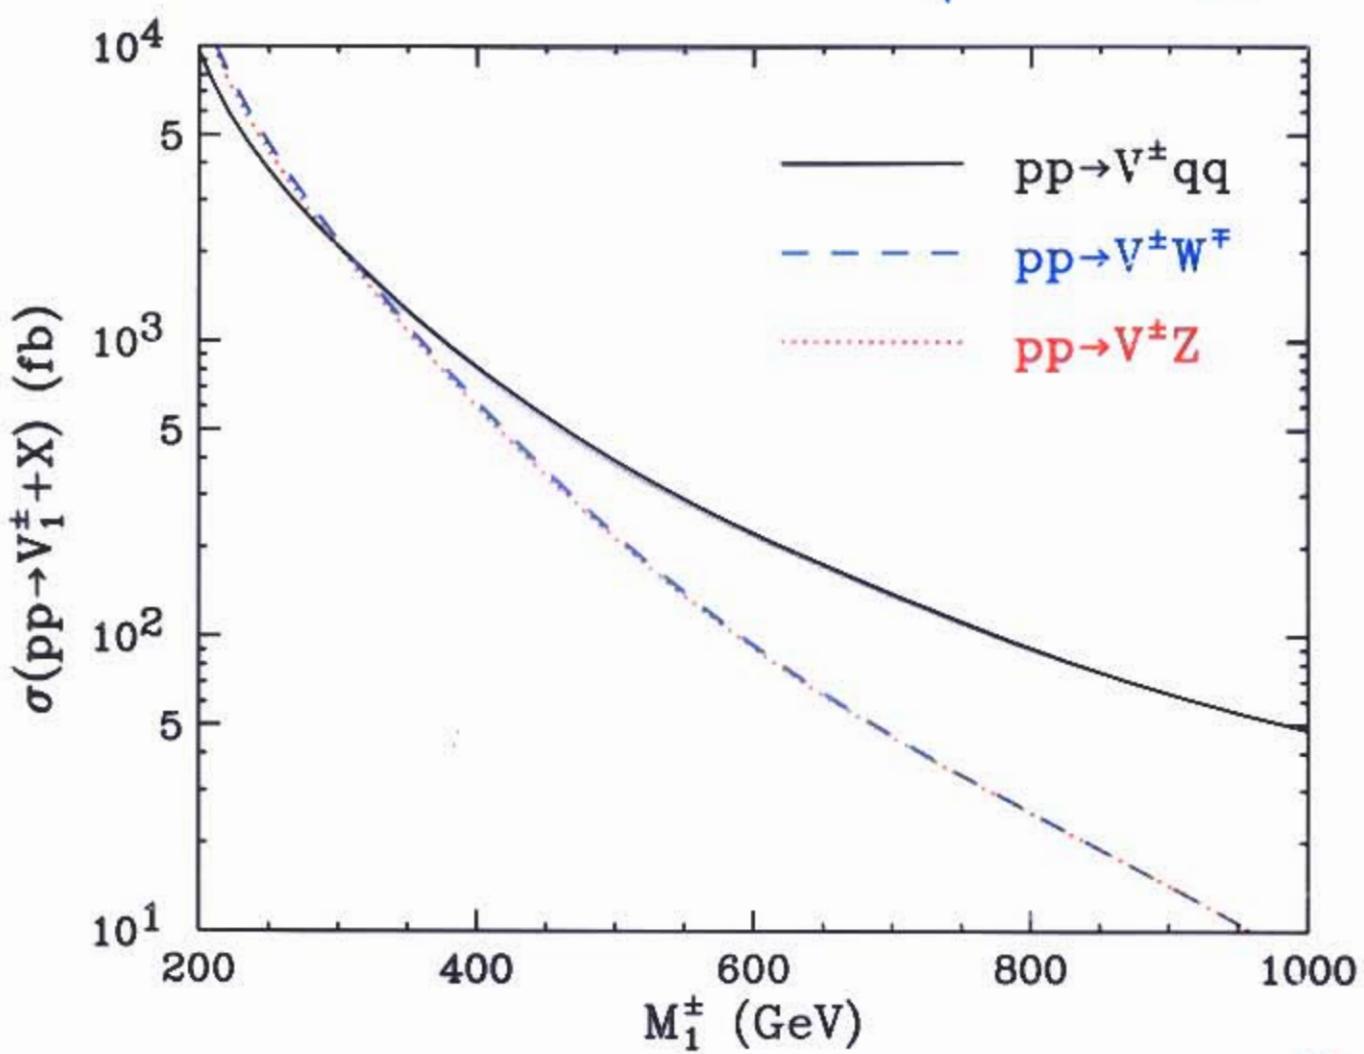

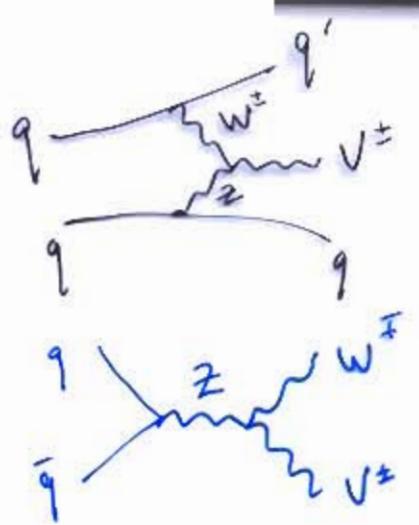

We can try to produce the new gauge bosons singly

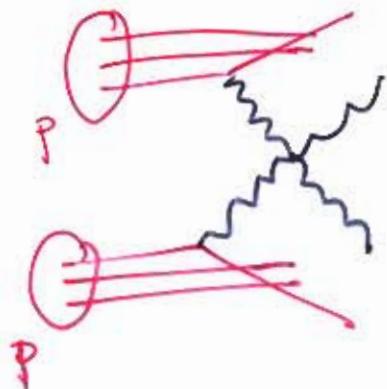

H. Davoudiasl et al. hep-ph/0512192

- Doesn't test the 'Higgsless' unitarity restoration mechanism
- $gg' W^{(k)}$ couplings are very model-dependent
(could be suppressed)

Too bad the LHC isn't a 'Massive Gauge Boson Collider'!

But it IS!

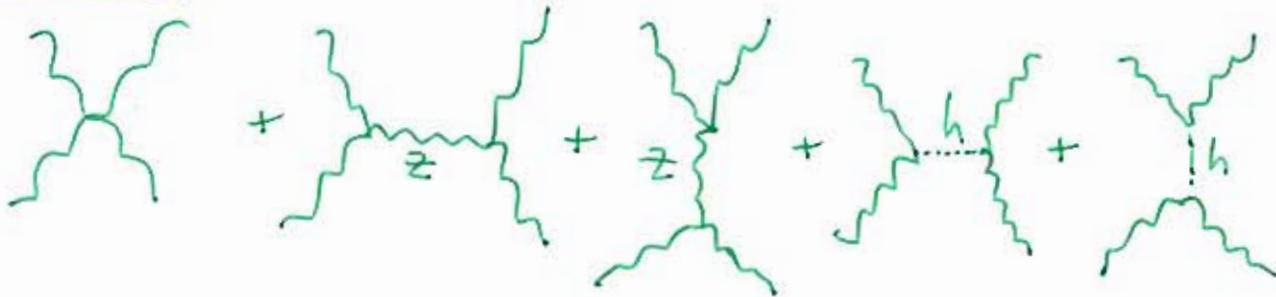

IF YOU COUNT
BREMSSTRAHUNG...

So we can actually test unitarity restoration of massive gauge boson scattering!

But what can we use to distinguish SM (with a Higgs) from Higgsless (or technicolor)?

$WW \rightarrow WW?$

SM:

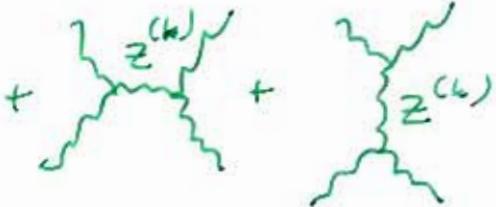

Higgsless:

"

"

"

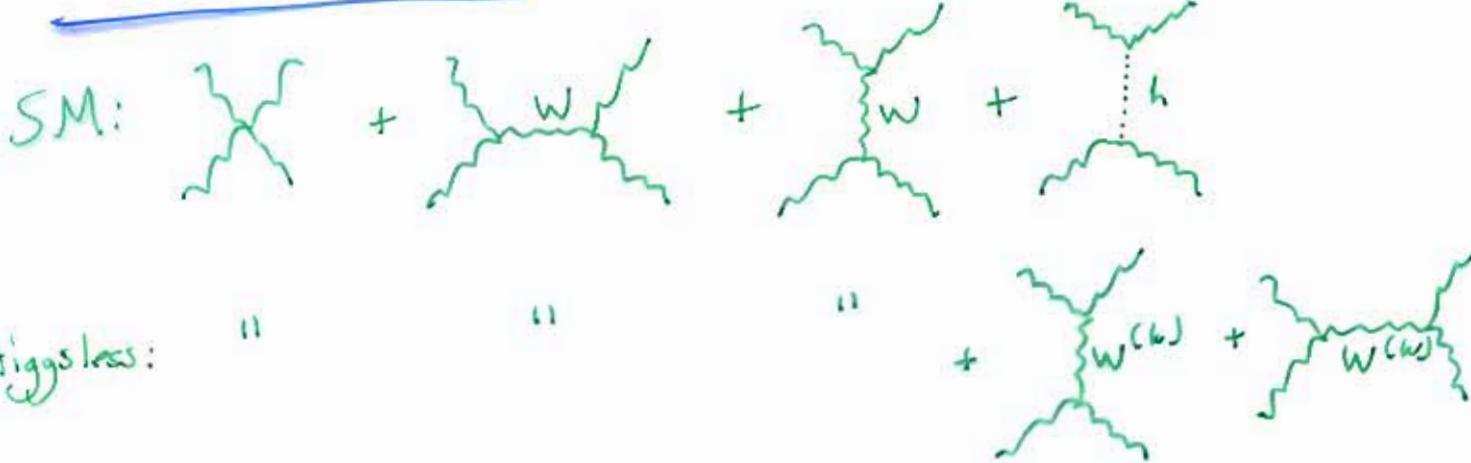

"

Hum. Same resonance structure.

Might get fooled ($m_h = m_{Z^{(w)}}$?)

$WZ \rightarrow WZ?$

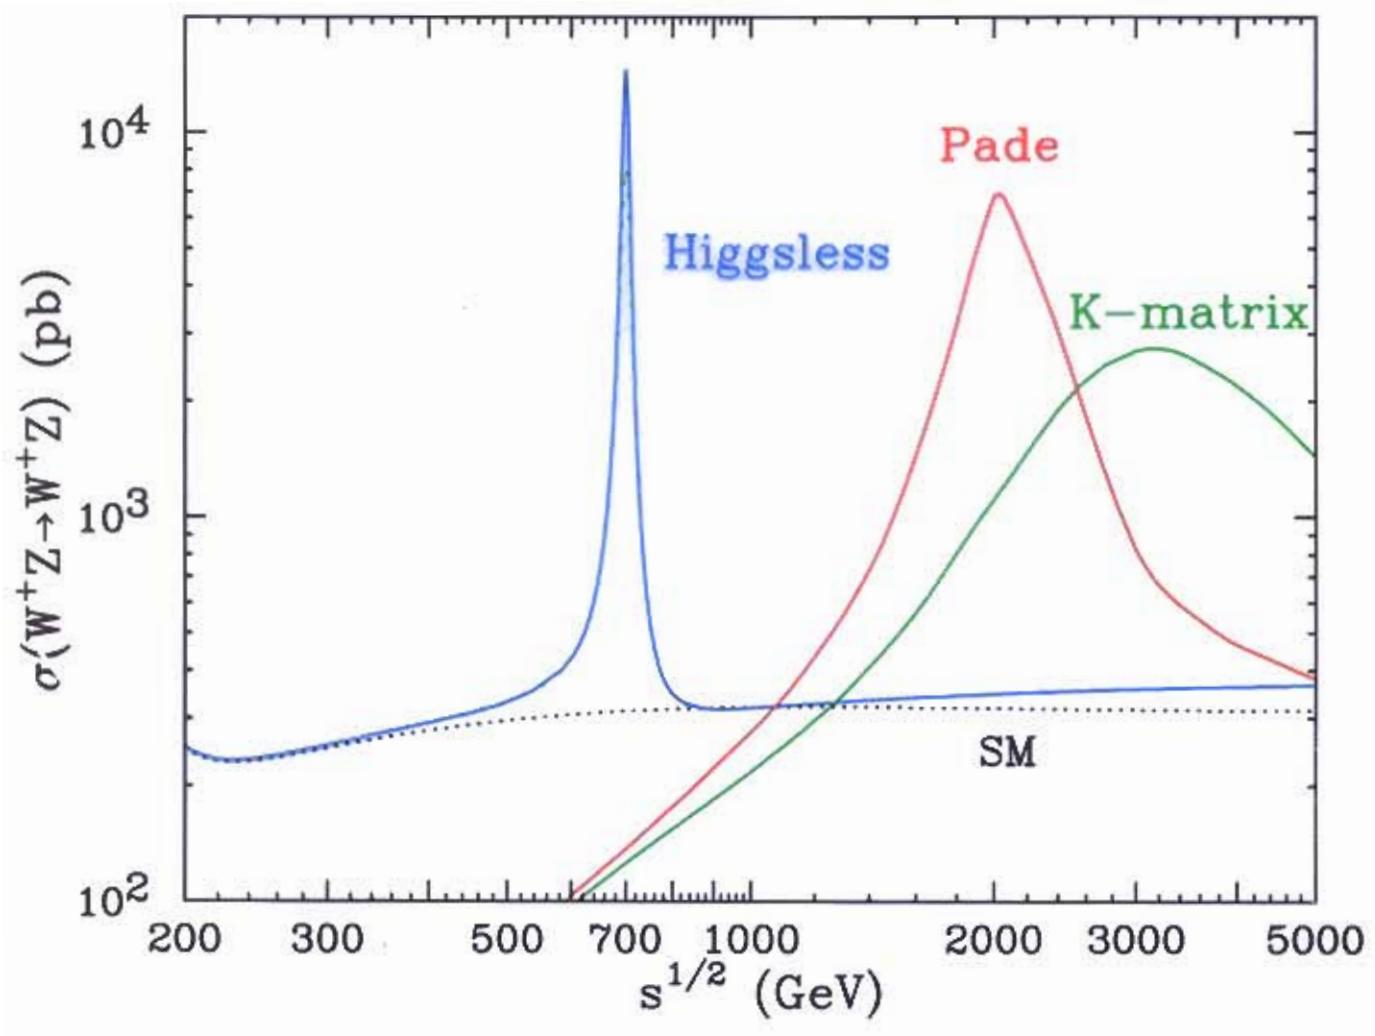

A different resonance structure!

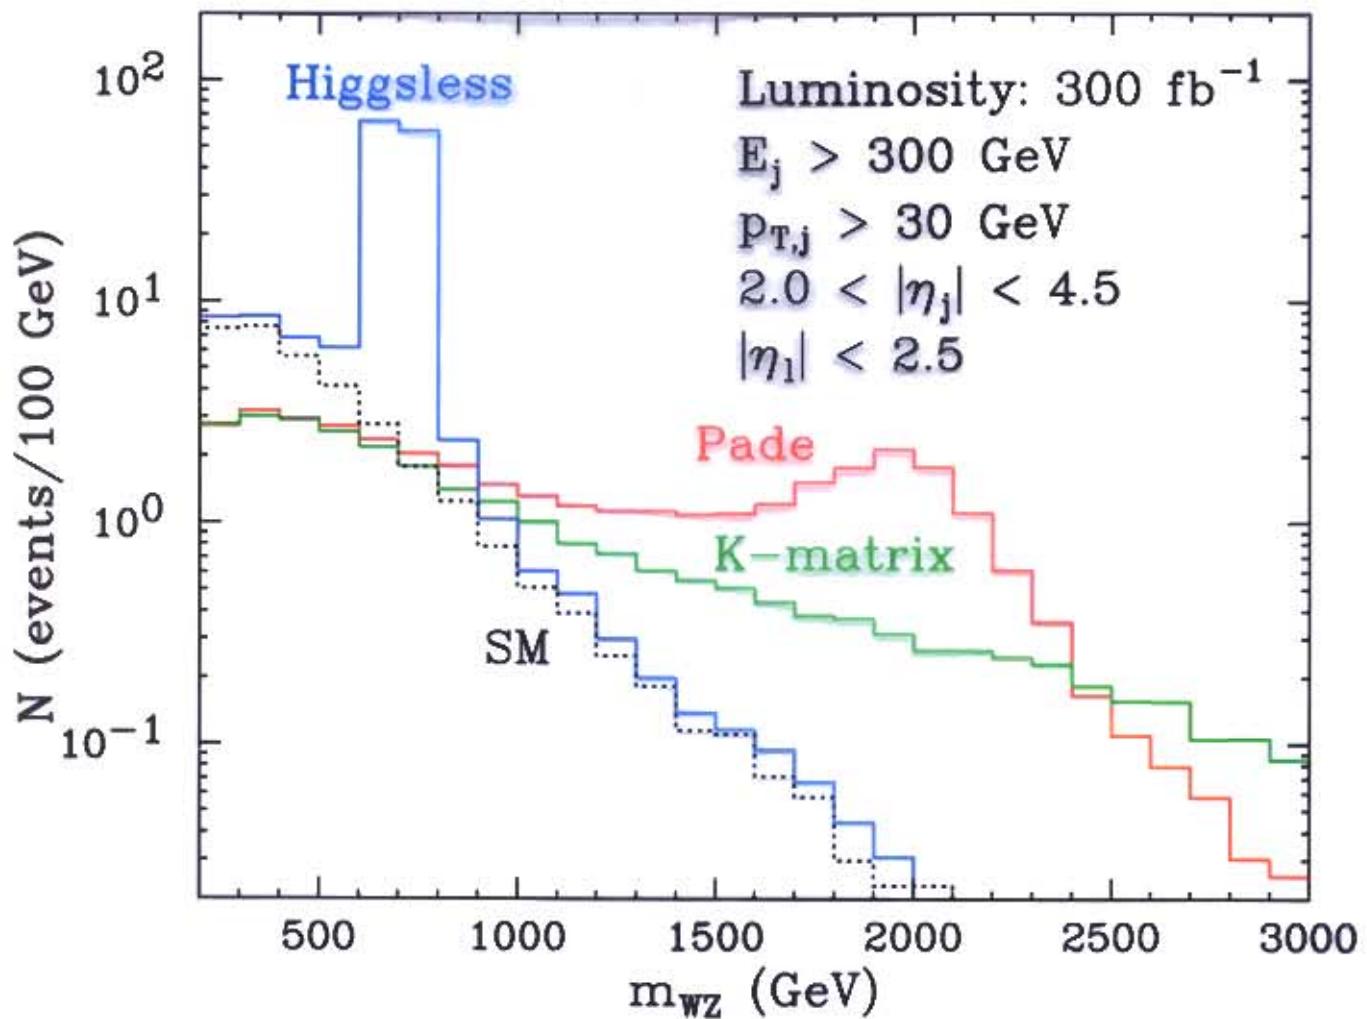

Distinguishable
s-channel
resonance?

	$WW \rightarrow WW$	$WZ \rightarrow WZ$
SM	No	No
Higgsless	No	Yes!

If we see an s-channel resonance in $WZ \rightarrow WZ$, we know it isn't the Higgs!

$2j + 3l + E_T$

Results of LHC Analysis

- 1 year of running at low luminosity:
 $(10 \text{ fb}^{-1} \text{ of data})$

LHC can probe Higgsless models up to

$$M_{\tilde{\chi}_1^{\pm}}^{\pm} \lesssim 550 \text{ GeV}$$

- To cover entire preferred range ($M_{\tilde{\chi}_1^{\pm}}^{\pm} \lesssim 1 \text{ TeV}$) requires 60 fb^{-1} of data

LHC: total luminosity $100 \text{ fb}^{-1} \sim 300 \text{ fb}^{-1}$
(expected)

Measuring $WW_{l=1}Z$ coupling

To measure $g_{WW_{l=1}}^{(i)}$, we need to determine

$$\sigma(pp \rightarrow 2j + W_{l=1}) \equiv \sigma_{\text{tot}}$$

We've only actually determined

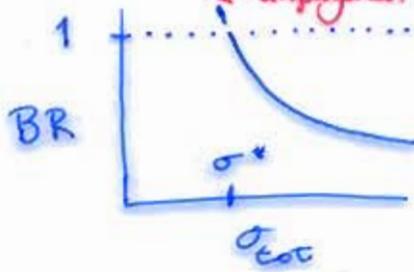

$$\sigma(pp \rightarrow 2j + 3e + \bar{\nu}_e) \rightarrow \sigma(pp \rightarrow 2j + W^{\pm} Z)$$

In the resonance region, what we observe is:

$$\text{Obs.} = \sigma_{\text{tot}} \text{BR}(W_{l=1}^{\pm} \rightarrow W^{\pm} Z) = \sigma_{\text{tot}} \frac{\Gamma(W_{l=1}^{\pm} \rightarrow W^{\pm} Z)}{\Gamma_{\text{tot}}(W_{l=1}^{\pm})}$$

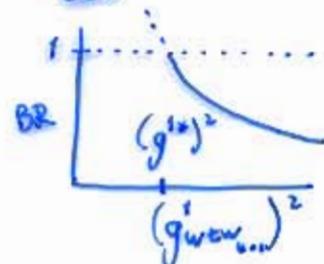

Since $\Gamma_{\text{tot}}(W_{l=1}^{\pm}) = \sum_i \Gamma(W_{l=1}^{\pm} \rightarrow \text{Final State } i)$, BR < 1

We measure one number for Obs., so Obs. = const. :

So we know $\sigma_{\text{tot}} > \sigma^*$

$$\text{Since } \sigma_{\text{tot}} \propto (g_{WW_{l=1}}^1)^2$$

we know $g_{WW_{l=1}}^1 > g^*$

From the sum rules, we have $g_{WW_{l=1}}^1 \sim \frac{g_{WW} M_Z^2}{\sqrt{3} M_{W_1}^{\pm} M_W}$

So Higgsless can be ruled out if we measure

$$g^* > \frac{g_{WW} M_Z^2}{\sqrt{3} M_{W_1}^{\pm} M_W}$$

Conclusions and Outlook

1. Higgsless Models provide a new, interesting alternative to Higgsed theories of EWSB.
2. Electroweak symmetry is broken by boundary conditions in extra dimensions. (4D realizations exist)
3. Unitarization of gauge boson scattering is achieved by KK gauge boson contributions. (Constrained by 'sum rules.')
4. The resonance structure in $W^{\pm}Z$ scattering in Higgsless models differs from that of SM, so the unitarization mechanism can be probed experimentally! (S -channel resonance in $W^{\pm}Z$ scattering is absent in S.M.)
Excellent prospects @ LHC can probe all of preferred parameter space with 60 fb^{-1} of data
5. Testing sum rules is more difficult, but some exclusion is possible.
6. Will probably help with a Linear Collider?
