

Electroweak baryogenesis in the MSSM

Electroweak baryogenesis in the MSSM

- The basics of EWBG in the MSSM
- Where do light stops (charginos) come from?
- Constraints from d_e , Ω_{CDM} , colliders ...

Baryon content of the universe

— WMAP: $\eta = \frac{n_B}{n_\gamma} = (6.1 \pm 0.4) \times 10^{-10}$

PDB 2004

- $n_{\bar{B}}$ is consistent with zero (only secondary production is known)
- no experimental (or theory) indication of large amounts of anti-matter

Genesis

— Baryo- or leptogenesis

- preexisting asymmetry $\rightarrow$ inflation $\rightarrow$ dynamic mechanism
- genesis: dynamical generation of asymmetry from symm. initial cond.s
- relies on thermodyn. phase transition (symmetric $\rightarrow$ asymmetric phase)
- has to satisfy the Sakharov conditions
 0. initially: matter-antimatter symmetric phase
 1. B is efficient before a thermodynamic phase transition
 2. C & CP interactions allow to generate asymmetry
 3. T preserves asym.: at phase transition universe falls out equilibrium, and new vacuum B conserving

— Baryo- or leptogenesis in the SM

- only CP distinguishes matter and anti-matter in the SM
- not enough CP in the SM to account for baryon asymmetry

Gavela et al '94; Huet, Sather '94

Baryogenesis

— Sakharov conditions for the MSSM in the early universe

1. ~~B~~: (classical) $B+L$ breaks anomalously

transitions between inequivalent $SU(2)_L$ gauge vacua lead to ~~B~~

2. ~~C~~ & ~~CP~~: new complex phases can arise when SUSY is softly broken

3. ~~T~~: expansion of universe $\rightarrow$ departure from equilibrium

1st order phase transition $\rightarrow$ even larger departure

— Electroweak baryogenesis

- concrete mechanism to generate baryon asymmetry
- consistent with particle physics and cosmology (inflation)
- utilizes existing phase transition: EWSB
- connected to weak scale $\rightarrow$ testable at Tevatron, LHC and ILC
- alternatives: GUT scale baryogenesis, leptogenesis, etc.

— Off the wall

- 1st order EW phase transition proceeds by nucleating bubbles

The Electroweak Phase Transition

- The order parameter for the transition is the local expectation value of the Higgs boson field, $\langle\phi\rangle$.

$$\langle\phi\rangle = 0 \Rightarrow SU(2)_L \times U(1)_Y \text{ is unbroken.}$$

$$\langle\phi\rangle \neq 0 \Rightarrow SU(2)_L \times U(1)_Y \rightarrow U(1)_{em}.$$

- $\langle\phi\rangle$ is the minimum of the effective potential at temperature T :

$$V_{eff} = (-\mu^2 + \alpha T^2)\phi^2 - \gamma T\phi^3 + \frac{\lambda}{4}\phi^4 + \dots$$

Bubble Nucleation

- First order phase transition:

$\Rightarrow$ degenerate minima at temperature T_c .

- The Universe starts in the $\langle \phi \rangle = 0$ phase.
- For $T < T_c$, the $\langle \phi \rangle \neq 0$ phase is favoured, but is blocked the potential.
- By tunnelling, small regions pass to the $\langle \phi \rangle \neq 0$ phase.
- This nucleates bubbles of $\langle \phi \rangle \neq 0$ phase.
- Bubbles expand until they fill all of space.

Off the wall mechanism (simplified)

Strongly 1st order PT $\rightarrow$ light stop (ξ higgs)

— Generation of $\eta = \frac{v_B}{v_Y}$ requires a strongly 1st order EW phase transition

- strongly 1st order EWPT $\leftrightarrow$ large order parameter: $\phi_c/T_c \gtrsim 1$
- type ξ strength of EWPT $\Leftarrow$ minimum of finite T effective potential

$$V_{\text{eff}}(\phi, T) = (-\mu^2 + \alpha T^2)\phi^2 - \gamma T \phi^3 + \frac{\lambda}{4} \phi^4 + \dots$$

- V_{eff} is minimal (for $\alpha, \mu \rightarrow 0$) if

$$\phi_c/T_c \sim \gamma/\lambda$$

$\rightarrow$ coefficient of cubic term (γ) determines order of phase transition

- γ generated by loops in (MS)SM

bosonic loops $\rightarrow \gamma \sim g^3$ (SM)

scalar loops $\rightarrow \gamma \sim y^3$ (MSSM)

tree level cubic $\rightarrow \gamma \sim A_\lambda$ (nMSSM)

- in MSSM light scalars induce strongly 1st order EW phase transition
- light, 3rd generation, right handed scalar invoked $\rightarrow$ light $t_1 \sim t_R$
- $t_2 \sim t_L > 1$ TeV needed to evade EW precision

Enough ~~CP~~ $\rightarrow$ light W_1 , small μ

— ~~CP~~ in the chargino sector

- SM: CKM phase is not enough for EWBG Gavela et al '94; Huet, Sather '94
- MSSM: additional sources of ~~CP~~ from μ term & soft SSB parameters
- charginos generate the largest ~~CP~~ contribution

— Enough ~~CP~~ if

$$M_2, \mu \lesssim 500 \text{ GeV} \text{ \& } \text{Arg}(M_2 \mu) \gtrsim 0.1$$

Carena, Seco, Quiros, Wagner 2002

$\rightarrow$ light $\tilde{W}_1$

— Minimal setup: $\text{Arg}(\mu) \gtrsim 0.1$ & $\text{Arg}(M_2) = 0$

$\leftrightarrow$ ~~CP~~ only in gaugino sector

- baryon asymmetry $\eta = \frac{n_B}{n_\gamma} \sim \sin(\text{Arg}(\mu))$

— Experimental constraints

- strongest limits from e^- EDM: $d_{e^-} \sim \sin(\text{Arg}(\mu))$
- less severe limits from $b \rightarrow s \gamma$

Electron electric dipole moment constraint

— e^- EDM is one of the most sensitive probes of EWBG

- EWBG requires complex phases $\rightarrow$ complex phases generate EDM
- EWBG requires $\text{Arg}(\mu) \gtrsim 0.1 \rightarrow 2 \times 10^{-28} e \text{ cm} \lesssim |d_e|$
- experimental limit: $|d_e| < 1.6 \times 10^{-27} e \text{ cm}$

Balázs, Carena, Menon, Morrissey, Wagner 2004

- Minimal model probed if d_e -limits improve by 10-100 (next few years)
- Escape e^- EDM: specific phase arrangements, $m_A > 1 \text{ TeV}$, non-min. models

EWBG MSSM: MSSM constrained by EWBG

- EW phase transition strongly 1st order → constraints on stop sector

$$m_{\tilde{t}_1} < m_t, \quad m_{\tilde{t}_2} \gtrsim 1 \text{ TeV},$$
$$0.3 < |X_t| / m_{\tilde{Q}_3} < 0.5,$$

constraint on h^0

$$m_h \lesssim 120 \text{ GeV}$$

- Enough $\epsilon\mu$ → constraints on charginos

$$M_2, \mu \lesssim 500 \text{ GeV},$$

$$\text{Arg}(M_2 \mu) \gtrsim 0.1$$

Carena, Seco, Quiros, Wagner 2002

- EDM limits → heavy 1st & 2nd generation scalars
- Scenario is strongly constrained by LEP2: $114 \text{ GeV} < m_{H^0}$
 - Does EWBG survive the stringent astro (collider & lowE) constraints?

The supersymmetric origin of matter

- $\tilde{t}_1$ - $\tilde{Z}_1$ coannihilation lowers the neutralino relic density to agree with WMAP where $m_{\tilde{t}_1} \sim m_{\tilde{Z}_1}$

Input parameters:

$\tan\beta = 7$, $m_A = 1000$ GeV, $\text{Arg}(\mu) = 1.571$
 $M_2 = M_1 g_2^2 / g_1^2$, $\text{Arg}(M_1) = \text{Arg}(M_2) = 0$, $M_3 = 1$ TeV
 $m_{U3} = 0$ GeV, $m_{Q3} = 1.5$ TeV, $X_t = 0.7$ TeV
 $m_{L3}, m_{E3}, m_{D3} = 1$ TeV
 $m_{L1,2}, m_{E1,2} = 10$ TeV
 $m_{Q1,2}, m_{U1,2}, m_{D1,2} = 10$ TeV

Legend:

$m_{t1} > m_{Z1}$	$m_{W1} < 103.5$ GeV
$\Omega h^2 > 0.129$	$\Omega h^2 < 0.095$
$0.095 < \Omega h^2 < 0.129$	
$\sigma_{SI} = \underline{3E-08} \quad \underline{3E-09} \quad \underline{3E-10}$ pb	
$m_{Z1} = \underline{120} \quad \underline{100} \quad \underline{80}$ GeV	
$d_e = \underline{1E-27} \quad \underline{1.2E-27} \quad \underline{1.4E-27}$ e cm	

Balázs, Carena, Menon, Morrissey, Wagner 2004

Collider implications $\rightarrow$ Caroline's & Ayres' talk

- If $\tilde{t}_1 \rightarrow c \tilde{Z}_1$ dominant
considerable part of
para. space observable
at Tevatron depending on L
- If $\tilde{t}_1 \rightarrow b \tilde{Z}_1 W$ or
 $m_{\tilde{t}_1} \lesssim 1.25 m_{\tilde{Z}_1}$
(Higgs resonance or
 $\tilde{t}_1 - \tilde{Z}_1$ coannihilation)
difficult at Tevatron
- LHC: similar situation
- ILC expected to cover
essentially all regions

Summary

- Universe carries **baryon-asymmetry**
- Baryogenesis: dynamic mechanism to explain the baryon-asymmetry
 - 1 SM anomalies lead to ~~B~~
 - 2 MSSM contains enough ~~$\mathcal{CP}$~~
 - 3 EW phase transition enhances departure from equilibrium
- Electroweak baryogenesis
 - "off the wall" mechanism satisfies **Sakharov conditions**
 - enough ~~$\mathcal{CP}$~~ $\leftrightarrow$ **light charginos**, small μ
 - strongly 1st order phase transition $\leftrightarrow$ **light stop**, (lightest) Higgs
- Experimental constraints
 - LEP2 **Higgs constraint** leaves only a small window in the MSSM
 - e^- **EDM** is one of the strongest constraint on $\text{Arg}(\mu) \leftrightarrow$ "stop split SUSY"
 - **neutralino relic abundance** narrows the parameter space to 'strips'
- **EWBG in the MSSM will be discovered/excluded by the ILC**
