

The supersymmetric origin of matter

- BMSSM = Baryogenesis + MSSM
- BMSSM $\rightarrow \Omega_{\text{WIMP}} + \eta_B$
- BMSSM benchmarks

Why do we need an ILC?

— Recent precise, direct, consistent astro observations → robust result

Supernovae, WMAP, SDSS

$$\Omega_M = 0.27 \pm 0.04$$

$$\Omega_\Lambda = 0.73 \pm 0.04$$

BBN, CMB

$$\Omega_B = 0.044 \pm 0.004 \Rightarrow$$

$$\Omega_{DM} = 0.22 \pm 0.04$$

- new form of matter: stable, non-bary., non-rel., weakly ia. → new physics

Baryon asymmetry

- BBN & WMAP: $\eta_B = \frac{n_B}{n_\gamma} = (6.1 \pm 0.4) \times 10^{-10} > 0 \rightarrow B\bar{B}$ asymmetry
- Baryo- (or lepto-) genesis has to satisfy the Sakharov conditions
 0. initial condition: matter-antimatter symmetric phase
early universe: existence of a phase transition to asymmetric phase
 1. B is efficient before the phase transition
 2. C & CP interactions allow to generate asymmetry
 3. T preserves asym.: at phase transition universe falls out equilibrium, and new vacuum B conserving
- Electroweak baryogenesis: dynamical generation of asymmetry from symmetric initial conditions
 - consistent with particle physics and cosmology (inflation)
 - utilizes existing phase transition: EWSB
 - connected to weak scale $\rightarrow$ testable at Tevatron, LHC and ILC

BMSSM: EW Baryogenesis + MSSM

- EW phase transition strongly 1st order → constraints on stop sector
 $m_{\tilde{t}_1} < m_t$, $m_{\tilde{t}_2} \gtrsim 1 \text{ TeV}$,
 $0.3 < |X_t| / m_{\tilde{Q}_3} < 0.5$,
constraint on h^0
 $m_h \lesssim 120 \text{ GeV}$
- Enough CP → constraints on charginos
 $M_2, \mu \lesssim 500 \text{ GeV}$,
 $\text{Arg}(M_2 \mu) \gtrsim 0.1$

Carena, Seco, Quiros, Wagner 2002

- EDM limits → heavy 1st & 2nd generation scalars
- Scenario is strongly constrained by LEP2: $114 \text{ GeV} < m_{h^0}$
 - Does EWBG survive the stringent astro (collider & lowE) constraints?

The origin of matter in the BMSSM

— Can SUSY explain the existence of dark matter and lack of anti-matter?

— Top-down: embed EWBG in an existing SSB model

- assume modified mSUGra: $m_0, m_{1/2}, A_0, \tan(\beta), \arg(\mu)$
- run (1-loop MSSM) RGE's up, to check unification:

$$m_{\tilde{U}_3}^2(M_{\text{GUT}}) \sim \frac{2}{3} m_{\tilde{Q}_3}^2 + 2A_t^2 + 11A_t M_1 - 53M_1^2 + O(\text{EW})$$

$$m_{\tilde{Q}_3}^2(M_{\text{GUT}}) \sim \frac{4}{3} m_{\tilde{Q}_3}^2 + A_t^2 + 5A_t M_1 - 46M_1^2 + O(\text{EW})$$

$$m_{H_1}^2(M_{\text{GUT}}) \sim -\frac{1}{12} M_1^2 + m_A^2 - \mu^2 + m_Z^2$$

$$m_{H_2}^2(M_{\text{GUT}}) \sim m_{\tilde{Q}_3}^2 + 3A_t^2 + 15A_t M_1 - 20M_1^2 + O(\text{EW})$$

- $m_{\tilde{Q}_3}^2, A_t, M_1, \mu$ constrained by EWBG $\Rightarrow$ no scalar (or gauge) unification
(~)
mSUGra, mGMSB or mAMSB (+phases) inconsistent with EWBG

— Bottom-up: let experimental data determine the low energy parameters

- assume EWBG in (n, N) MSSM (no assumption on SSB): BMSSM
- use data ($\eta_B, \Omega_{\text{WIMP}}, e^- \text{EDM}, B(b \rightarrow s\gamma), g_{\mu-2} \dots$) to narrow parameter space
- simplifying assumptions: $\tilde{Z}_1$ is LSP & only μ acquires a complex phase

The supersymmetric origin of matter

— Can baryon asymmetry & neutralino dark matter be simultaneously generated in the MSSM?

Input parameters:

$\tan\beta = 7$, $m_A = 1000$ GeV, $\text{Arg}(\mu) = 1.571$
 $M_2 = M_1 g_2^2 / g_1^2$, $\text{Arg}(M_1) = \text{Arg}(M_2) = 0$, $M_3 = 1$ TeV
 $m_{U3} = 0$ GeV, $m_{Q3} = 1.5$ TeV, $X_t = 0.7$ TeV
 $m_{L3}, m_{E3}, m_{D3} = 1$ TeV
 $m_{L1,2}, m_{E1,2} = 10$ TeV
 $m_{Q1,2}, m_{U1,2}, m_{D1,2} = 10$ TeV

Legend:

$m_{t1} > m_{z1}$	$m_{W1} < 103.5$ GeV
$\Omega h^2 > 0.129$	$\Omega h^2 < 0.095$
$0.095 < \Omega h^2 < 0.129$	
$\sigma_{SI} = \underline{3E-08} \quad \underline{3E-09} \quad \underline{3E-10} \text{ pb}$	
$m_{Z1} = \underline{120} \quad \underline{100} \quad \underline{80} \text{ GeV}$	
$d_e = \underline{1E-27} \quad \underline{1.2E-27} \quad \underline{1.4E-27} \text{ e cm}$	

Balázs, Carena, Menon, Morrissey, Wagner 2004

The supersymmetric origin of matter

- $\tilde{t}_1$ - $\tilde{Z}_1$ coannihilation lowers the neutralino relic density to agree with WMAP where $m_{\tilde{t}_1} \sim m_{\tilde{Z}_1}$

Input parameters:

$\tan\beta = 7$, $m_A = 1000$ GeV, $\text{Arg}(\mu) = 1.571$
 $M_2 = M_1 g_2^2 / g_1^2$, $\text{Arg}(M_1) = \text{Arg}(M_2) = 0$, $M_3 = 1$ TeV
 $m_{U3} = 0$ GeV, $m_{Q3} = 1.5$ TeV, $X_t = 0.7$ TeV
 $m_{L3}, m_{E3}, m_{D3} = 1$ TeV
 $m_{L1,2}, m_{E1,2} = 10$ TeV
 $m_{Q1,2}, m_{U1,2}, m_{D1,2} = 10$ TeV

Legend:

$m_{t1} > m_{Z1}$	$m_{W1} < 103.5$ GeV
$\Omega h^2 > 0.129$	$\Omega h^2 < 0.095$
$0.095 < \Omega h^2 < 0.129$	
$\sigma_{SI} = \underline{3E-08} \quad \underline{3E-09} \quad \underline{3E-10} \text{ pb}$	
$m_{Z1} = \underline{120} \quad \underline{100} \quad \underline{80} \text{ GeV}$	
$d_e = \underline{1E-27} \quad \underline{1.2E-27} \quad \underline{1.4E-27} \text{ e cm}$	

Balázs, Carena, Menon, Morrissey, Wagner 2004

The supersymmetric origin of matter

- Annihilation via the h^0 (A^0) resonance also lowers the neutralino relic abundance to agree with WMAP where $2m_{\tilde{Z}_1} \sim m_{h^0(A^0)}$

Balázs, Carena, Menon, Morrissey, Wagner 2004

Collider implications $\rightarrow$ Ayres' & Caroline's talk

- If $\tilde{t}_1 \rightarrow c \tilde{Z}_1$ dominant
considerable part of
para. space observable
at Tevatron depending on L
- If $\tilde{t}_1 \rightarrow b \tilde{Z}_1 W$ or
 $m_{\tilde{t}_1} \lesssim 1.25 m_{\tilde{Z}_1}$
(Higgs resonance or
 $\tilde{t}_1 - \tilde{Z}_1$ coannihilation)
difficult at Tevatron
- LHC: similar situation
- ILC expected to cover
essentially all regions

BMSSM Benchmarks

1 $\{|\mu|, M_1\} = \{350, 110\}$ GeV

Arg (μ) optional ($\tilde{t}_1 \tilde{Z}_1$ coann. insensitive to it)

2 $\{|\mu|, M_1\} = \{400, 60\}$ GeV

in Tevatron / LHC reach (resonance ann.)

Strategy to explore collider phenomenology

Les Houches light $\tilde{t}$ WG

(Allanach, Balázs, Galanti, Ghosh, Godbole, Guchait, Lari, Schumacher, Shepherd, Sopczak, Zhukovarena ...)

Benchmark point selection : 1, 2 and modified SPS1a (Ayres)

Benchmark point analysis

BMSSM 1

- $\tilde{t}_1 \tilde{Z}_1$ mass gap small

- no Tevatron (LHC) reach

- ILC reach → Les Houches

BMSSM 2

- Tevatron (LHC) reach?

BMSSM 3

- No Tevatron (LHC) reach

- ILC reach → Ayres

Direct CDM detection experiments

- Future **nucleon-WIMP** detection experiments will probe considerable part of all regions (including $\tilde{t}_1$ - $\tilde{Z}_1$ coannihilation)

Balázs, Carena, Menon, Morrissey, Wagner 2004

Electron electric dipole moment constraint

— e^- EDM is one of the most sensitive probes of EWBG

- EWBG requires complex phases $\rightarrow$ complex phases generate EDM
- EWBG requires $\text{Arg}(\mu) \gtrsim 0.1 \rightarrow 2 \times 10^{-28} e \text{ cm} \lesssim |d_e|$
- experimental limit: $|d_e| < 1.6 \times 10^{-27} e \text{ cm}$

Balázs, Carena, Menon, Morrissey, Wagner 2004

- Minimal model probed if d_e -limits improve by 10-100 (next few years)
- Escape e^- EDM: specific phase arrangements, $m_A > 1 \text{ TeV}$, non-min. models

Summary

- Cold dark matter seems to be out there and neutralinos are excellent candidates for it
- Baryogenesis explains the baryon asymmetry based on the electroweak phase transition in the MSSM
 - simultaneous electroweak baryogenesis and neutralino cold dark matter is viable in the MSSM $\Rightarrow$ all matter might just originate from SUSY!
- Does matter have a supersymmetric origin?
 - e^- EDM measurements are the most sensitive probes of this model
 - Tevatron has a good chance to find the light stop, but even the
 - Large Hadron Collider will not cover the full para. space
 - International Linear Collider covers most of the parameter region
 - direct dark matter searches can find the neutralino in this scenario
 - complementary collider, dark matter & low energy experiments can uncover..
