## Probing New Physics with Astrophysical Neutrinos

### Nicole Bell The University of Melbourne

Nicole Bell, The University of Melbourne

Neutrino 2008, Christchurch, New Zealand, 30 May 2008

1

## Introduction

New Physics -> New Particle Physics

 $\rightarrow$ 

Astrophysical Neutrinos Neutrinos from beyond the solar system

## Neutrinos detected so far:

MeV energies
 Neutrinos from the Sun and SN1987A

Up to ~ 1 TeV (SuperK and others)
 & above 1 TeV (AMANDA, Frejus)
 Only atmospheric neutrinos

Higher energies
 Upper limits on fluxes

BUT, excellent prospects for many experiments now coming on line

## Astrophysical neutrino beam

May eventually be as useful/revealing as the solar neutrino beam

But we first need to detect and calibrate it!

4

## Ngutrino Sources

Cosmic beam dumps", eg, active galactic nuclei, gamma ray bursts, supernovae remnants.

 → Optically thin sources → v, γ and CR fluxes related. (e.g. Waxman & Bahcall; Mannheim, Protheroe & Rachen.)
 → Optically thick → "hidden" sources → neutrinos only

♦ Cosmogenic (GZK) neutrinos. (Guaranteed)
Interaction of cosmic rays with the cosmic microwave background

Annihilation or decay of dark matter
 →Fluxes related to dark matter cross-sections and density distributions.

## Astrophysical flux limits

**AMANDA** collaboration 2007

## Above the electroweak scale

UHE neutrinos probe energies far above the EW scale
 Sensitivity to new physics via new contributions to cross-sections.

- Neutrino-nucleon cross-section must be extrapolated to energies where we have no experimental data points. (Ghandi, Quigg, Reno and Sarcevic)
- Suppressed cross-sections (w.r.t. simple parton model):
- → Possible new physics?
- → Saturation effects at high energy

(Growth of cross-section with energy must saturate to preserve unitarity, Froissart bound.)

- Enhanced cross-sections:
- → Exchange of towers of Kaluza Klein gravitions (Feng & Shapere)
- → Black hole production (Banks & Fischler; Giddings & Thomas; Dimopoulos & Landsberg.)
- → Electroweak Instantons (Fodor, Katz, Ringwald, & Tu.)

## $event rates \rightarrow cross sections$

- Event rates depend upon (flux)×(cross-section)
   How do we disentangle astrophysics from particle physics?
- Events rates for up and down going neutrinos depend differently on neutrino cross-sections. Kusenko & Weiler, PRL 88, 161101 (2002)

Kusenko & Weiler, PRL 88, 161101 (2002) Feng & Shapere, PRL 88, 021303 (2002)

- Enhanced cross-sections would:
- $\rightarrow$  increase down-going event rate
- $\rightarrow$  decrease up-going event rate (due to greater absorption in Earth)

Amanda already provides constraints at 6 TeV CoM energy:

$$E_{\nu} = 10^{7.25} \text{ GeV} \implies \sqrt{s} = 6 \text{ TeV}$$

## Cross-sections/fluxes at leeCube

Anchordoqui, Feng & Goldberg, PRL 96, 021101 (2006).

## Neutrino probe of SUSY

Albuquerque, Burdman and Chacko, PRL 92, 221802 (2004)

•Neutrinos make NLSP pairs in the Earth

•NLSP is charged and long lived  $\rightarrow$  long range.

Energetic NLSP pairs make a new signal in IceCube  $\rightarrow$  Two parallel charged tracks, ~ 100 m apart.

Can also use atmospheric neutrinos. Ando, Beacom, Profumo, Rainwater, JCAP 0804, 029 (2008)

## Neutrino Production

\* pp and pγ interactions produce charged and neutral pions

$$pp \rightarrow NN + \text{pions}; \quad p\gamma \rightarrow p\pi^0, \ n\pi^+$$

Neutrinos from pion decay:

$$\rightarrow \nu_{\mu} + \mu^{+} \\ \downarrow \\ \overline{\nu}_{\mu} + e^{+} + \nu_{e}$$

**\*** Expected flavor ratio at the source:  $v_e : v_\mu : v_\tau = 1:2:0$ 

♦ After oscillations:  $V_{\mu} \leftrightarrow V_{\tau}$   $V_e: V_{\mu}: V_{\tau} = 1:1:1$ 

Learned & Pakvasa

• For hadronic production,  $\phi_{_{V}} \sim \phi_{_{\gamma}}$ 

 $\pi^+$ 

## Deviations from 1:1:1 - Particle Physics

#### **Exotic neutrino properties**

- Neutrino decay (Beacom, Bell, Hooper, Pakvasa, & Weiler)
- •CPT violation (Barenboim & Quigg)
- •Oscillation to steriles (Dutta, Reno and Sarcevic)
- •Oscillations with tiny delta  $\delta m^2$  (Crocker, Melia, & Volkas; Berezinsky et al.)
- •Pseudo-Dirac mixing (Beacom, Bell, Hooper, Learned, Pakvasa, & Weiler)
- •Magnetic moment transitions (Enqvist, Keränen, Maalampi)
- •Mass varying neutrinos (Fardon, Nelson & Weiner; Hung & Pas)

• ••

## Flavor Ratios – v decay

Neutrino invisible decays are not ruled out, and would greatly alter the ratios

Other new physics can lead to different ratios

Beacom, Bell, Hooper, Pakvasa, Weiler, PRL 90, 181301 (2003); Beacom, Bell, Hooper, Pakvasa, Weiler, PRD 69, 017303 (2004)

Nicole Bell, The University of Melbourne

## Ultimate long-baseline experiment

Astrophysical sources provide baselines almost as big as the visible universe.

This allows a sensitivity to oscillations with tiny  $\delta m^2$ 

Eg. Oscillation modes that have a sub-dominant or completely negligible effect on the solar or atmospheric neutrinos may show up here.

Crocker, Melia and Volkas (2000, 2002) Berezinsky, Narayan and Vissani (2002) Keranen, Maalampi, Myyrylainen and Riittinen (2003) Beacom, Bell, Hooper, Pakvasa, Learned, and Weiler (2004)

Neutrino 2008, Christchurch, New Zealand, 30 May 2008

15

#### **Pseudo-Dirac Neutrinos**

Neutrinos appear to be Dirac, but in fact have subdominant Majorana mass terms.

 $\rightarrow$ Oscillations driven by tiny mass differences.

→ Would show up in  $\nu_{1a}, \nu_{1s}$  astro-nu flavor ratios.

## Deviations from 1:1:1 - Astrophysics

#### **Galactic** β beams:

Photo-disintegration of heavy nuclei  $\rightarrow$  neutrons $\rightarrow$  Pure  $\overline{v_e}$  flux  $v_e : v_\mu : v_\tau = 1 : 0 : 0 \rightarrow 5 : 2 : 2$  after oscillations

#### Muon-damped source: If muons loose energy before decaying: $v_e: v_\mu: v_\tau = 0: 1: 0 \rightarrow 1: 2: 2$ after oscillations

#### We can do oscillation experiments with such sources!

Measuring the 1-3 mixing angle and the CP phase:

e.g. Serpico & Kachelreiss, PRL 94, 21102 (2005); Winter, PRD 74, 033015 (2006); Blum, Nir, & Waxman, arXiv:0706.2070; Pakvasa, Rodejohann, & Weiler, arXiv:0711.4517. Measuring mixing parameters with a  $\beta$  beam source:  $v_e: v_\mu: v_\tau = 1:0:0$

## Can we measure it?

FLAVOR INFORMATION

**Muon tracks** – CC interactions of  $v_{\mu}$ 

□Showers – neutral current interactions of all flavors, plus CC interactions of  $v_e$  and  $v_{\tau}$ .

Double bang and lollipop events - only  $v_{\tau}$ 

**Glashow resonance** – only  $\overline{v}_{e}$ , at E=6.3PeV.

To determine the  $v_e I v_{\mu}$  ratio  $\rightarrow$  compare muon tracks to showers.

Shower

Nicole Bell, The University of Melbourne

**Muon Track** 

Neutrino 2008, Christchurch, New Zealand, 30 May 2008

**Double-Bang** 

#### Muons/Showers rate for different electron fractions.

(Waxman-Bahcall flux, 1yr at Icecube)

Beacom, Bell, Hooper, Pakvasa, and Weiler, PRD 68, 093005 (2003)

Nicole Bell, The University of Melbourne

Constraining Dark Matter with Neutrino Astrophysics

> Dark Matter may be a source of high energy neutrinos

Nicole Bell, The University of Melbourne

#### WIMP annihilation in the Sun/Earth

❖ WIMPS captured by the gravitational field of Sun
 ❖ Annihilation in Sun → all products absorbed except neutrinos

#### **Neutrinos and Dark Matter - indirect detection**

♦ Annihilation in our Galaxy
→ look for flux coming from Galactic center

Annihilations in galaxies throughout the universe
 cosmic diffuse flux

Despite being harder to detect than gamma rays, neutrinos provide important information and <u>strong</u> <u>bounds.</u>

# If the dark matter is the lightest new particle:

All final states except neutrinos produce gamma rays,

 $\rightarrow$ Bound the *total* cross-section with the neutrino signal limit i.e. Assume Br("invisible") = 100%

## Upper bounds on the dark matter total annihilation cross-section

Beacom, Bell, & Mack, PRL99, 231301, 2007.

Also:

Yuksel, Horiuchi, Beacom, & Ando, PRD 76, 123506, 2007.

Kachelriess and Serpico, PRD 76, 063516 (2007).

Bell, Dent, Jacques, & Weiler, arXiv:0805.3423

#### Dark matter annihilation – MeV mass

90% C.L. Super-Kamiokande bound

Palomares-Ruiz & Pascoli, PRD 77, 025025 (2008)

Nicole Bell, The University of Melbourne

## Comparison of neutrino and photon limits on dark matter annihilation

Mack, Jacques, Beacom, Bell, and Yuksel, arXiv:0803.0157

Nicole Bell, The University of Melbourne

#### Radiative corrections to neutrino processes give photons <sup>29</sup>

 $\chi \chi \rightarrow v \overline{v}$  is accompanied by:  $\chi \chi \rightarrow v \overline{v} \overline{Z} \rightarrow \text{gamma rays}$ 

#### But direct neutrino limits are stronger!

Kachelriess and Serpico, PRD 76, 063516 (2007).

Bell, Dent, Jacques, & Weiler, arXiv:0805.3423

Nicole Bell, The University of Melbourne

#### Dark Matter Lifetime

#### Photons $X \rightarrow X'\gamma$ ... strong limit

Neutrinos X→vv ... <u>model-independent</u> limit

## Outlook

 Have not yet detected astrophysical neutrinos beyond the Sun and SN1987A.

• Many new detectors coming on line, with excellent prospects of seeing a signal.

 Will have complementary data from neutrinos, gamma rays and cosmic rays.

• Flavor discrimination important for both understanding the production mechanism, and probing exotic particle physics.

• High energy neutrino observation/limits provide important and restrictive *dark matter* limits.
