Abstract

A description of Standard Model background Monte Carlo samples produced for studies related to future hadron colliders.

1 Introduction

The final missing piece of the Standard Model (SM), the Higgs boson, was discovered in 2012 by the ATLAS and CMS experiments at the Large Hadron Collider (LHC) \cite{1, 2}. However,
the SM leaves several important questions unanswered, whose explanation requires Beyond
the SM (BSM) physics. Despite the remarkable success of the LHC physics program, no
statistically significant evidence for BSM physics has been observed.

The discovery of BSM physics may be just around the corner at the LHC. Alternatively,
the mass scale of BSM physics may be outside the reach of the LHC, requiring a future
high-energy collider to uncover. A $\sqrt{s} = 100$ TeV $pp$ collider has therefore been proposed
to eventually supplant the LHC [3].

The cross sections for SM background processes such as $V(W^+/Z) + \text{jets}$ and $t\bar{t}$ are
very large at $\sqrt{s} = 100$ TeV. Accurately modeling the tails of kinematic distributions for
these processes requires production of sophisticated Monte Carlo (MC) samples with large
statistics. The production of such samples, following an approach similar to that adopted
for Snowmass 2013 [4, 5, 6], is described here.

2 Monte Carlo Simulation

High-statistic $V + \text{jets}$ and $t\bar{t}$ background Monte Carlo samples were produced for $\sqrt{s} = 13$
and 100 TeV $pp$ colliders, using MadGraph5_AMC@NLO v3.3.1 [7], Pythia8 v8.306 [8],
and Delphes v3.5.0 [9], with computing resources provided by the Open Science Grid [10].
MadGraph5_AMC@NLO was used to simulate $pp$ hard scatter matrix elements. Parton
shower and hadronization were performed with Pythia8. Delphes parameterized detector
simulation was used to account for the detector response.

2.1 Hard Scatter

Hard scatter matrix elements were computed in the four-flavor scheme at leading-order
(LO) accuracy in the strong coupling constant with MadGraph5_AMC@NLO. On-shell
heavy resonances ($V, t, H$) were treated as stable particles. Radiated partons are allowed
(with transverse momentum $p_T \geq 20$ GeV and pseudorapidity $|\eta| < 5$), up to a total of four
final state particles. The NNPDF31_nnlo_as_0118 parton distribution function was used [11].

So-called “gridpacks” were produced for streamlined operation on the OSG computing
grid using the makeGridpacks.sh script, contained within the MCProd package (git tag:
v1.2nobias).* Configuration cards can be found in the Cards directory.

2.2 Parton Shower

On-shell heavy resonances were decayed using Pythia8, neglecting spin correlation effects.
Parton shower and hadronization were also simulated with Pythia8, using the CMS CP5
tune [12]. $k_T$-MLM matching and merging of radiation from the matrix-element and parton
shower was performed using the MG5AMC_PY8_INTERFACE [13]. For the $V + \text{jets}$ ($t\bar{t}$)

*https://github.com/Snowmass21-software/MCProd/releases/tag/v1.2nobias
samples, a matching scale $X_{Q\text{CUT}} = 40$ (80) GeV was used. In both cases, $Q\text{CUT}$ is taken to be $1.5 \times X_{Q\text{CUT}}$.

### 2.3 Detector Response

The detector response was simulated using DELPHES. The parameterized detector performance is based on test beam data and full-simulation of a future FCC-hh detector [14]. The effect of pileup interactions is not simulated explicitly; instead, the parameterized efficiency and resolution for various physics objects include the expected degradation due to pileup interactions.

### 2.4 Workflow

A summary of the production workflow is shown in Fig. 1. The MadGraph5\_aMC@NLO output (a standard LHE file [15]) serves as input to Pythia8. The Pythia8 output (in HepMC format [16]) serves as input to both Rivet and Delphes. Delphes produces a standard ROOT output [17], while Rivet produces output in the YODA format [18]. In addition to storing the final outputs from this workflow, intermediate outputs are retained as well.

**Figure 1:** A summary of the production workflow.
3 Validation

Validation of the matching/merging of phase space for parton emission covered by the matrix element and parton shower is performed by studying differential jet rates. Comparison of the $\sqrt{s} = 13$ TeV samples to unfolded LHC data was performed using Rivet [18].

3.1 Matching/Merging

Suitability of the matching/merging settings is confirmed based on the differential jet rates, shown for $\sqrt{s} = 100$ TeV $W$ + jets events in Figure 2. Similar plots for $Z$ + jets and $t\bar{t}$ samples are shown in the appendix. These observables represent the scale at which an $N$-jet event transitions to an $N+1$-jet event, and exhibit a smooth transition.

3.2 Comparison to Data

The Rivet toolkit provides a convenient mechanism to compare simulated MC to unfolded collider data, using a variety of predefined analysis routines.

The $W$ + jets sample was validated using the CMS_2017_I1610623 routine, which targets $W(\rightarrow \mu\nu)$+jets production. This routine selects events with a muon and transverse mass $m_T \geq 50$ GeV. Muons are required to have $p_T \geq 25$ GeV and $|\eta| < 2.4$.

The $Z$ + jets sample was validated using the CMS_2019_I1753680 routine, which targets $Z(\rightarrow \ell\ell)$+jets production, where $\ell = e/\mu$. This routine selects events with a pair of opposite-sign electrons or muons. In both cases, electrons and muons are required to have $p_T \geq 25$ GeV and $|\eta| < 2.4$.

The $t\bar{t}$ sample was validated using the CMS_2018_I1663958 routine, which targets events with semi-leptonic decay of top pairs. This routine selects events with an electron or muon (with $p_T \geq 30$ GeV and $|\eta| < 2.4$). $W$ and $t$ candidates are formed from the lepton, jets and missing transverse energy $E_T$, by minimizing the difference between the true mass and the reconstructed mass for these candidates.

4 Results

Cross sections for $\sqrt{s} = 13$ and 100 TeV background processes are given in Table 1.

Table 1: Calculated cross sections for SM background processes at $\sqrt{s} = 13$ and 100 TeV.

A comparison of the $\sqrt{s} = 13$ TeV simulation and data is shown in Figures 3, 4, and
Figure 2: Differential jet rate distributions for $\sqrt{s} = 100$ TeV $W +$ jets events, showing log$_{10}$ of the merging scale. The upper left (right) plot represents a transition from a 0-jet event to a 1-jet (1-jet event to a 2-jet) event. The lower left (right) plot represents a transition from a 2-jet event to a 3-jet (3-jet event to a 4-jet) event.
5, for $W + \text{jets}$, $Z + \text{jets}$, and $t\bar{t}$ samples, respectively. Additional comparison plots are available on the web.\footnote{W + jets: https://jstupak.web.cern.ch/noBias/W/, Z + jets: https://jstupak.web.cern.ch/noBias/Z/, $t\bar{t}$: https://jstupak.web.cern.ch/noBias/tt/} The agreement between simulated $Z + \text{jets}$ and $t\bar{t}$ samples and data is reasonable; while the overall discrepancy is approximately 10\%, the shapes are not generally well reproduced in the simulation, leading to bin-by-bin discrepancies of up to 50\% or more in certain regions of phase space. The agreement between the simulated $W + \text{jets}$ and data is worse, at the 50\%-level overall. There is a general overproduction of jets, particularly at high $p_T$. The source of this discrepancy is under investigation. However, some event shapes are well described by the simulation.

5 Conclusion

The production of SM background MC samples for $\sqrt{s} = 13$ and 100 TeV $pp$ colliders has been described. A comparison of the $\sqrt{s} = 13$ TeV simulation to data from the LHC was performed. While the agreement between simulated $Z + \text{jets}$ and $t\bar{t}$ events and collision data is reasonable, the modeling of $W + \text{jets}$ events is not acceptable. The source of this mismodeling is under investigation. Due to the similarities in production between the $W + \text{jets}$ and $Z + \text{jets}/t\bar{t}$ samples, we do not advise using any of these samples for physics studies, until the discrepancy is understood.

ACKNOWLEDGEMENTS

This research was done using services provided by the OSG Consortium \cite{OSG}, which is supported by the National Science Foundation awards \#2030508 and \#1836650. We would also like to thank Olivier Mattelaer for significant MadGraph5_aMC@NLO assistance.
