#### Abstract

A parametric integral representation for the amplitudes of renormalized perturbation theory is developed. The result is a closed, well-defined and unique renormalized amplitude to be associated with an arbitrary Feynman graph. By unique we mean that the renormalized amplitude is explicitly independent of the initial choice of independent integration momenta and the routing of external momenta through the graph. Our prescription is applicable to conventionally unrenormalizable as well as renormalizable theories. It is shown that for renormalizable theories, our representation is formally equivalent to the usual recursive subtraction formula for writing renormalized amplitudes and hence can be interpreted in terms of mass and coupling constant renormalization. To investigate the practical advantages of this formalism, a calculation of the fourth order vacuum polarization in Quantum Electrodynamics is carried out.

## I. Introduction

Parametric integral representations of Feynman amplitudes have been used for a variety of purposes (1) ever since the beginning of modern quantum field theory. They have been especially useful in the investigation of analyticity properties in perturbation theory and in carrying out calculations in quantum electrodynamics. The purpose of the present work is to develop a parametric integral form for renormalized Feynman amplitudes which is convenient for discussing some of the formal aspects of renormalization theory and which will provide a general framework for carrying out higher order calculations in quantum electrodynamics.

With any subtraction scheme for expressing renormalized amplitudes, there are basically two formal problems. It must be shown that the subtractions lead to a unique finite renormalized amplitude and that the cutoff dependent terms which are subtracted can be related to Lagrangian counter terms and hence to renormalization effects. After presenting a definition of renormalized amplitudes, we will discuss both of these problems and then illustrate the calculational advantages of this formalism by looking at the fourth order vacuum polarization contribution in quantum electrodynamics.

In Section II, we will derive a parametric integral form for an arbitrary unsubtracted, regularized Feynman amplitude. We will employ the notation and several of the results of Nakanishi (2) to express the result in a way which is explicitly independent of the routing of external momenta through the graph and the choice of independent integration momenta. The integrand of the parametric integral will reflect only the structure of the
corresponding graph. We will list the properties of the parametric functions in the integrand and give the condition for convergence of the integral in the absence of regularization.

In Section III, a parametric integral representation for renormalized Feynman amplitudes will be established using the result of Section II as a starting point. The necessary subtractions will be made by making use of the well-known formula (3.1) for the remainder of the Taylor series. This will avoid the topological complexities associated with overlapping divergences and lead to a unique nonrecursive expression applicable to arbitrary interactions.

Section IV will be devoted to showing that the parametric integral form of renormalized amplitudes is a well-defined expression in the absence of regularization. The proof involves a careful power counting in the parametric integral and does not rely on Weinberg's proof (3) of Dyson's power counting theorem which involves an unjustified contour rotation.

In Section V, we will show that the expression for renormalized amplitudes developed here is equivalent to a recursive subtraction formula in which the subtraction terms are directly related to Lagrangian counter terms (4) and hence, in the case of renormalizable theories, to renormalization effects.

In Section VI, we will carry through a calculation of the fourth order vacuum polarization contribution in quantum electrodynamics using the formalism developed in Section III. There are several features of this formalism which together simplify the calculation considerably. First of all, since the momentum integrals have been carried out the only momentum in the problem is the external momentum and hence the trace calculations become
trivial. By the use of (3.1), the subtractions will be made at the origin of momentum space. .This will eliminate the infrared divergent terms which appear in the intermediate stages of the calculation when the subtractions are made on the mass shell. We will be primarily interested in the high energy behavior of the vacuum polarization. In this energy region, each of the graphs of Figure 6 gives contributions proportional to $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ and $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$. It is well-known from direct calculation (5) and from renormalization group techniques (6) that the $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contributions cancel and that the leading term in fourth order goes as $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$. In our approach, this cancellation occurs at an early stage of the calculation without actually carrying out the integrals giving rise to the $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contributions.

The present work is similar in some respects to the approach of Yennie and Kuo (7) which is formulated in momentum space rather than parameter space.

## II. Parametric Integral Formulas

We begin by considering an arbitrary proper Feynman graph G containing $N$ directed internal lines and $n$ independent basic circuits. The momentum of each line $r$ will be denoted by $p_{r}+q_{r}$, where $p_{r}$ is an integration momentum and $q_{r}$ is a constant momentum which will be related to the momenta external to the graph. Due to momentum conservation at each vertex, only $n$ of the $p_{r}$ will be independent integration (loop) momenta. If there are v vertices, we have

$$
\begin{equation*}
\mathrm{n}=\mathrm{N}-\mathrm{v}+1 \tag{2.1}
\end{equation*}
$$

the +1 accounting for over-all momentum conservation.
With each line in the graph will be associated a propagator of the form

$$
\begin{equation*}
\frac{i Z_{r}\left(p_{r}+q_{r}\right)}{\left(p_{r}+q_{r}\right)^{2}-m_{r}^{2}+i \epsilon} \tag{2.2}
\end{equation*}
$$

where $Z_{\mathbf{r}}$ depends upon the type of propagator. Then, apart from constant factors and vertex $\gamma$-matrices, the amplitude will be

$$
\begin{equation*}
W^{(G)}=\int \prod_{i=1}^{n} d^{4} p_{i} \prod_{r \in G}\left\{\frac{i Z_{r}\left(p_{r}+q_{r}\right)}{\left(p_{r}+q_{r}\right)^{2}-m_{r}^{2}+i \epsilon}\right\} \tag{2.3}
\end{equation*}
$$

where we have chosen a particular set of the $p_{r}$ as independent integration momenta. A convenient starting point for changing (2.3) into parametric form is to express the propagator (2.2) in the form (8)

$$
\begin{align*}
& \frac{i Z_{r}\left(p_{r}+q_{r}\right)}{\left(p_{r}+q_{r}\right)^{2}-m_{r}^{2}+i \epsilon}=  \tag{2.4}\\
& \left.\int_{0}^{\infty} d x_{r} Z_{r}\left(\frac{1}{i x_{r}} V_{\ell_{r}}\right) \exp \left[i x_{r}\left(\left(p_{r}+q_{r}\right)^{2}+\left(p_{r}+q_{r}\right) \cdot \ell_{r}-m_{r}^{2}+i \epsilon\right)\right]\right|_{\ell_{r}=0}
\end{align*}
$$

The ultra-violet divergences show up in parametric form as singularities of the integrand at the lower limit of the parametric integration. To avoid these divergences, we regularize each propagator by changing the lower limit of the parametric integration from zero to a small positive constant $\rho$. Substituting this into (2.3) gives a regularized amplitude

$$
\begin{align*}
& W_{\rho}^{(G)}=\int \prod_{i=1}^{n} d^{4} p_{i} \times \\
& \times \prod_{r \in G}\left\{\left.\int_{\rho}^{\infty} d x_{r} Z_{r}\left(\frac{1}{i x_{r}} \nabla_{\ell_{r}}\right) \exp \left[i x_{r}\left(\left(p_{r}+q_{r}\right)^{2}+\left(p_{r}+q_{r}\right) \cdot \ell_{r}-m_{r}^{2}+i \epsilon\right)\right]\right|_{\ell_{r}=0}\right\} \tag{2.5}
\end{align*}
$$

Since the propagators have been regularized, the momentum and parametric integrations in (2.5) can be interchanged and the momentum integrations can be carried out by diagonalizing the quadratic form in the exponential and repeatedly employing the formula

$$
\begin{equation*}
\int d^{4} p e^{i a p^{2}}=\frac{\pi^{2}}{\mathrm{ia}^{2}} \tag{2.6}
\end{equation*}
$$

The details of this procedure are similar to those carried out by Nakanishi (2) and so we omit them here. The result can be written in a form explicitly independent of the original choice of loop momenta.

$$
\begin{align*}
W_{\rho}^{(G)}= & \left(\frac{\pi^{2}}{i}\right)^{n} \int_{\rho}^{\infty} d x_{G} \prod_{r \in G} z_{r}\left(\frac{1}{i x_{r}} \nabla_{\ell}\right) \frac{l}{U^{2}}  \tag{2.7}\\
& \times\left.\exp \left[i \sum_{r \in G} x_{r}\left(q_{r}^{2}+q_{r} \cdot \ell_{r}-m_{r}^{2}+i \epsilon\right)-\frac{i}{T} \sum_{C} U_{C}\left(\sum_{r \in C} \pm x_{r}\left(q_{r}+\frac{l_{r}}{2}\right)\right)^{2}\right]\right|_{\ell=0}
\end{align*}
$$

where the sum $\sum_{\mathbf{C}}$ is over all possible simple closed circuits in $G$ and

$$
\begin{equation*}
\int_{\rho}^{\infty} \mathrm{dx}_{\mathrm{G}}=\prod_{\mathrm{r} \in \mathrm{G}} \int_{\rho}^{\infty} \mathrm{dx}_{\mathrm{r}} . \tag{2.8}
\end{equation*}
$$

U and $\mathrm{U}_{\mathrm{C}}$ are functions of the integration parameters only.

$$
\begin{equation*}
\mathrm{U}=\sum \mathrm{x}_{\nu_{1}} \mathrm{x}_{\nu_{2}} \ldots \mathrm{x}_{\nu_{\mathrm{n}}} \tag{2.9}
\end{equation*}
$$

where the summation is over all possible sets $\left\{\nu_{1} \ldots \nu_{n}\right\}$ such that $p_{\nu_{1}}, p_{\nu_{2}}, \ldots p_{\nu_{n}}$ is a possible set of independent integration momenta and

$$
\begin{equation*}
\mathrm{U}_{\mathrm{C}}=\sum \mathrm{x}_{\nu_{1}} \mathrm{x}_{\nu_{2}} \ldots \mathrm{x}_{\nu_{\mathrm{n}-1}} \tag{2.10}
\end{equation*}
$$

where the summation is over all possible sets $\left\{\nu_{1} \ldots \nu_{n-1}\right\}$ such that none of the corresponding lines belongs to $C$ and such that $p_{\nu_{1}}, p_{\nu_{2}} \cdots p_{\nu_{n-1}}$ is a possible set of independent integration momenta. The double sign in (2.7) corresponds to the relative direction of lines in circuit $C$.

* The initial assignment of directions to internal lines is arbitrary. However, it is convenient to use the direction of fermion propagation for the fermion lines. Then each member of a closed fermion loop or of fermion path through the graph will have the same direction. With this choice, each $\mathrm{Z}_{\mathrm{r}}$ will always be of the form $\left(+\frac{1}{\mathrm{ix}_{\mathrm{r}}} \not \ddot{\nabla}_{\ell \mathrm{r}}+\mathrm{m}_{\mathrm{r}}\right)$.

As an example, consider the self energy graph of Figure 1.

A simple self energy graph.

Figure 1
where circuit A is composed of lines 1,2, and 3 and circuit B is composed of lines 3,4 , and 5 . Then

$$
\begin{align*}
& \mathrm{U}=\left(\mathrm{x}_{1}+\mathrm{x}_{2}\right)\left(\mathrm{x}_{4}+\mathrm{x}_{5}\right)+\mathrm{x}_{3}\left(\mathrm{x}_{1}+\mathrm{x}_{2}+\mathrm{x}_{4}+\mathrm{x}_{5}\right)  \tag{2.11}\\
& \mathrm{U}_{\mathrm{A}}=\mathrm{x}_{4}+\mathrm{x}_{5}
\end{align*}
$$

Expression (2.7) still seems to depend upon how the external momenta are routed through the graph since this determines the values of the various $q_{r}$ 's. To see that this is not the case, we interchange orders of summation in (2.7) and re-express it in the form

$$
\begin{align*}
W_{\rho}^{(G)}= & \left(\frac{\pi^{2}}{i}\right)^{n} \int_{\rho}^{\infty} d x_{G} \prod_{r \in G} Z_{r}\left(\frac{1}{i x_{r}} \nabla_{\ell}\right) \frac{1}{U^{2}} \\
& \times\left.\exp \left[i\left(V+\sum_{r \in G} x_{r} \ell_{r} \cdot Y_{r}-\frac{1}{4} \sum_{r, S \in G} x_{r} x_{s} \ell_{r} \cdot \ell_{S} x_{r s}\right)-i \sum_{r \in G} x_{r}\left(m_{r}^{2}-i \epsilon\right)\right]\right|_{\ell=0} \tag{2.19}
\end{align*}
$$

where

$$
\begin{align*}
V & =\sum_{r \in G} x_{r} q_{r}^{2}-\frac{1}{U} \sum_{C} U_{C}\left(\sum_{r \in C} \pm x_{r} q_{r}\right)^{2}  \tag{2.13a}\\
Y_{r \mu} & =q_{r \mu}-\frac{1}{U} \sum_{C \in C(r)} U_{C}\left(\sum_{s \in C} \pm x_{s} q_{s \mu}\right)  \tag{2.13b}\\
x_{r s} & =\frac{1}{U} \sum_{C \in C(r, s)} \pm U_{C} \tag{2.13c}
\end{align*}
$$

$C(r)$ is the set of all simple closed circuits in $G$ containing line $r$ and $C(r, s)$ is the set of all simple closed circuits containing both line r and line s . The double sign in (2.13b) and (2.13c) corresponds to the relative direction of lines $r$ and $s$ on circuit $C$.

The functions $\mathrm{V}, \mathrm{Y}_{\mathrm{r} \mu}$, and $\mathrm{X}_{\mathrm{rs}}$ appear in a somewhat different form in the work of Nakanishi (2) and, as he shows, $\mathrm{Y}_{\mathrm{r} \mu}$ and V can be written in terms of the external momenta in a way which is explicitly route-independent. The reader is referred to the paper of Nakinishi for a proof of this, and the results are simply reproduced here.

We first consider the case when $G$ is a self energy graph. Then $V$ and $Y_{r \mu}$ are given by

$$
\begin{array}{r}
\therefore \therefore \therefore \quad \therefore \quad \therefore \quad \frac{W}{U} k^{2} \\
Y_{r \mu}=\left(\frac{1}{U} \sum_{C \in C(0, r)} \pm W_{C}\right) k_{\mu} \tag{2.14h}
\end{array}
$$

where $\mathrm{k}_{\mu}$ is the external momentum and W and $\mathrm{W}_{\mathrm{C}}$ are defined as follows. From the self energy graph $G$, we form a graph $G^{\prime}$ by connecting the external lines of $G$ and label the new line as 0 with parameter $x_{0}$.

Graph formed by joining the external lines of the self energy graph $\mathrm{G}^{\prime}$.

Figure 2

Then $W$ is just the $U$ function of the graph $G^{\prime}$ with $x_{0}$ set equal to zero and $W_{C}$ is the $U_{C}$ function of the graph $C \quad$ The double sign in (2.14b) corresponds to the relative direction of lines $0 \mathrm{ar}:$ on circuit $C$. Clearly the forms (2.14a) and (2.14b) are independent of the routing of $k_{\mu}$ through the graph.

* The direction of external lines is defined by the momentum labeling.

As an example, we return to the self energy graph of Figure 2. For this graph,

$$
\begin{gather*}
\mathrm{W}=\mathrm{x}_{1} \mathrm{x}_{2}\left(\mathrm{x}_{3}+\mathrm{x}_{4}+\mathrm{x}_{5}\right)+\mathrm{x}_{4} \mathrm{x}_{5}\left(\mathrm{x}_{1}+\mathrm{x}_{2}+\mathrm{x}_{3}\right)+\mathrm{x}_{3}\left(\mathrm{x}_{1} \mathrm{x}_{5} \div \mathrm{x}_{2} \mathrm{x}_{4}\right) \\
\mathrm{Y}_{1 \mu} \tag{2.15}
\end{gather*}=\frac{1}{\mathrm{U}}\left[\left(\mathrm{x}_{2} \mathrm{x}_{3}+\mathrm{x}_{2} \mathrm{x}_{5}+\mathrm{x}_{3} \mathrm{x}_{5}\right)+\mathrm{x}_{2} \mathrm{x}_{4}\right] \mathrm{k}_{\mu},
$$

and similarly for the other $\mathrm{Y}_{\mathrm{r}}$ 's.
We next consider the general case when $G$ has $l$ external momenta $k_{1}, k_{2}, \ldots, k_{\ell}$ which we take to be directed inward. Then by momentum conservation,

$$
\begin{equation*}
\sum_{i=1}^{\ell} k_{\ell}=0 \tag{2.16}
\end{equation*}
$$

For this graph, V is given by

$$
\begin{equation*}
V=\frac{1}{U} \sum_{i>j} w^{i j}\left(-k_{i} \cdot k_{j}\right) \tag{2.17}
\end{equation*}
$$

where $W^{i j}$ is the $W$ function for the self energy graph formed from $G$ by setting $\mathrm{k}_{\mathrm{i}}=-\mathrm{k}_{\mathrm{j}}$ and all others equal to zero. Similarly, $\mathrm{Y}_{\mathrm{r} \mu}$ is given by

$$
\begin{equation*}
\mathrm{Y}_{\mathrm{r} \mu}=\sum_{\mathrm{i}=1}^{\ell-1} \mathrm{Y}_{\mathrm{r} \mu}^{\ell \mathrm{i}} \tag{2.18}
\end{equation*}
$$

where $\mathrm{Y}_{\mathrm{r} \mu}^{\ell \mathrm{i}}$ is the $\mathrm{Y}_{\mathrm{r} \mu}$ frunction for the self energy graph formed from G by setting $k_{\ell}=-k_{i}$ and all others equal to zero.

Equation (2.12) is the representation of an arbitrary unsubtracted, regularized ampitude which we shall use as a staiting point for defining a renormalized amplitude. If each field in the theory is a spin zero field and if there are no derivative couplings, then each $Z_{r}$ is equal to one and (2.12) becomes simply

$$
\begin{equation*}
\mathrm{w}_{\rho}^{(\mathrm{G})}=\left(\frac{\pi^{2}}{\mathrm{i}}\right)^{\mathrm{n}} \int_{\rho}^{\infty} \mathrm{dx}_{\mathrm{G}} \frac{1}{\mathrm{U}^{2}} \exp \left[\mathrm{iV}-\mathrm{i} \sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right] \tag{2.19}
\end{equation*}
$$

This simplified form will be used in the discussions of Sections IV and V.
In developing a parametric form for renormalized amplitudes, it will be necessary to know the properties of the parametric functions appearing in the integrand in (2.12). To this end, we will list several of these properties here. The first six follow immediately from the definitions and the proof of the seventh is given by Nakanishi (2).

1) The functions $U, U_{C}, W^{i j}$ and $W_{C}^{i j}$ are homogeneous polynomials in the $\mathrm{x}_{\mathrm{r}}$ with the following order:

$$
\begin{array}{cl}
\mathrm{U}: n \text {-th order } & \mathrm{W}^{\mathrm{ij}}:(n+1) \text {-th order } \\
\mathrm{U}_{\mathrm{C}}:(\mathrm{n}-1) \text {-th order } & \mathrm{W}_{\mathrm{C}}^{\mathrm{ij}}: n \text {-th order }
\end{array}
$$

2) The functions $V, Y_{r}$ and $X_{r s}$ are homogeneous with respect to the $\mathrm{x}_{\mathrm{r}}$ with the following order:

$$
\mathrm{V}: \text { first order } \quad \mathrm{Y}_{\mathrm{r}}: \text { O-th order } \quad \mathrm{X}_{\mathrm{rs}}:(-1) \text {-th order }
$$

3) The functions $U, U_{C}, W^{i j}$ and $W_{C}^{i j}$ are all non-negative definite in the region of integration.

$$
\mathrm{U}, \mathrm{U}_{\mathrm{C}}, \mathrm{w}^{\mathrm{ij}}, \mathrm{w}_{\mathrm{C}}^{\mathrm{ij}} \geq 0 \text { in } \mathrm{x}_{\mathrm{r}} \geq 0, \mathrm{r}=1,2, \ldots, \mathrm{~N}
$$

4) $V$ vanishes only when $x_{r}=0$, for all $r \in C^{\prime}$, where $C^{\prime}$ is any closed circuit in $G$. The same holds for $U_{C}$ for all $C^{\prime}$ in $G$ except $C^{\prime}=C$. $W^{i j}$ vanishes only when $x_{r}=0$, for all $r \in C^{\prime}$ where $C^{\prime}$ is any closed circuit in $G$ or any path through $G$ connecting external lines $i$ and $j$. The same holds for $W_{C}^{i j}$ for all $C^{\prime}$ in $G$ except $C^{\prime}=C$.
5) Let H be a collection of lines in $G$ containing $m$ independent closed circuits. Then $U$ has an $m$-th order zero at $x_{r}=0$, for all $r \in H$. The same holds for $U_{C}$ apart from the circuit. $C$. For $W^{i j}$ and $W_{C}^{i j}$, the order of the zero in $\mathrm{m}+1$ if H includes a path through the graph connecting lines i and $j$, and $m$ if it does not.
6) $X_{r s}$ has a first order pole only when $x_{t}=0$, for all $t \in C$, where $C \in C(r, s)$.
7) Let $H$ be a union of $m$ independent circuits in $G$. Let $R$ be the graph formed from $G$ by shrinking each line of $H$ to a point. Denote the $U$ function for $G,(H, R)$ by $U_{G},\left(U_{H}, U_{R}\right)$. Then

$$
\begin{equation*}
\mathrm{U}_{\mathrm{G}}=\mathrm{U}_{\mathrm{H}} \mathrm{U}_{\mathrm{R}}+\mathrm{U}_{\mathrm{G}}^{\prime} \tag{2.20}
\end{equation*}
$$

where $U_{G}^{\prime}$ is at least of order $m+1$ in $x_{r}, r \in H$. Similarly for $W_{G}^{i j}$,

$$
\begin{equation*}
W_{G}^{i j}=U_{H} W_{R}^{i j}+W_{G}^{i j}{ }^{\prime} \tag{2.21}
\end{equation*}
$$

where $W_{G}^{i j}$ ' is at least of order $m+1$ in $x_{r}, r \in H$. We will only use subscripts
on the parametric functions when it is necessary to avoid confusion.
$\because$ The limit $\rho \rightarrow 0$ in $W_{\rho}^{(\mathrm{G})}$ may not exist due to the existence of nonintegrable poles of the integrand at the lower limit of the parametric integration. These divergences correspond to the "ultra-violet" divergences of the momentum space representation of Feynman amplitudes. At the upper end of the integration, the integrand dies off exponentially due to the negative imaginary part associated with each mass.

To make this more precise, we first look at the momentum representation (2.5) of the amplitude. We consider a particular sub-integration corresponding to some proper subgraph $S_{i}$ consisting of $N_{i}$ lines and $n_{i}$ independent circuits. Let $z_{r}$ be the power of the momentum in the numerator factor $Z_{r}$. The degree of divergence $d_{i}$ for the subgraph $S_{i}$ is defined to be the power of the integration momenta internal to $S_{i}$ in the numerator minus the power of the integration momenta internal to $S_{i}$ in the denominator:

$$
\begin{equation*}
d_{i}=4 n_{i}+\sum_{r \in S_{i}} z_{r}-2 N_{i} \tag{2.22}
\end{equation*}
$$

According to Dyson's power counting theorem, the limit $\rho \rightarrow 0$ in $\mathrm{W}_{\rho}^{(\mathrm{G})}$ will exist providing that $\mathrm{d}_{\mathrm{i}}<0$ for all proper subgraphs $\mathrm{S}_{\mathrm{i}}$ of G .

The same condition holds for the existence of the limit $\rho \rightarrow 0$ in the parametric form (2.12). According to property 5 , $U$ will have an $n_{i}$-th order zeroat $x_{r}=0$, for all $r \in S_{i} . T^{\prime} \nabla_{l}$ operators will bring $Y_{r}$ and $X_{r S}$ factors into the numerator. $Y_{r}$ is zeroth order in any subset of the parameters while $\mathrm{X}_{\mathrm{rs}}$ has poles given by property 6. By inspection of (2.12), the order of the pole introduced by the $V_{\ell}$ operators is

$$
\begin{align*}
& \because \frac{1}{2} \sum_{r \in S_{i}} z_{r} \text { for } \sum_{r \in S_{i}} z_{r} \text { even }  \tag{2.23}\\
& \frac{1}{2}\left(\sum_{r \in S_{i}} z_{r}-1\right) \text { for } \sum_{r \in S_{i}} z_{r} \text { odd }
\end{align*}
$$

It follows that the numerator will contain sufficient powers of the parameters $\mathbf{x}_{\mathbf{r}}, \mathbf{r} \in \mathrm{S}_{\mathbf{i}}$ to make the corresponding sub-integration converge provided that

$$
\begin{equation*}
2 N_{i}>4 n_{i}+\sum_{r \in S_{i}} z_{r} \tag{2.24}
\end{equation*}
$$

This is just the condition $d_{i}<0$. A rigorous proof of the power counting theorem can easily be constructed using the parametric form and, in fact, it will be a special case of the proof of finiteness for renormalized amplitudes to be presented in Section IV.

## III. Renormalized Amplitudes

Using the power counting theorem as a guide, we will define the renormalized amplitude corresponding to a Feymman graph $G$ by locating those proper subgraphs $S_{i}$ of $G$ for which $d_{i} \geq 0$ and performing a sufficient number of subtractions to make the corresponding sub-integration convergent in the limit $\rho \rightarrow 0$. These subtractions can conveniently be made by using the well-known formula for the remainder of a Taylor series

$$
\begin{equation*}
f(x)-f(0)-\cdots-\frac{f^{(n)}(0)}{n!} x^{n}=\int_{0}^{1} d \xi \frac{(1-\xi)^{n}}{n!}\left(\frac{\partial}{\partial \xi}\right)^{n+1} f(\xi x) \tag{3.1}
\end{equation*}
$$

Combining this method of performing subtractions with the parametric integral form of Feynman amplitudes will yield our parametric integral form for renormalized amplitudes.

We consider an arbitrary Feynman graph $G$ and begin by performing the subtractions corresponding to a particular subgraph $S_{i}$ for which $d_{i} \geq 0$. Working in the momentum representation, we choose a set of integration momenta for $G$ so that exactly $n_{i}$ of them are internal to $S_{i}$. Let the external momenta of $S_{i}$ be $k_{1}, k_{2}, \ldots, k_{l_{i}}$. They will depend upon the integration momenta of $G$ not internal to $S_{i}$ and the external momenta of $G$. The unsubtracted regularized amplitude is

$$
\begin{equation*}
\mathrm{w}_{\rho}^{(\mathrm{G})}\left[\mathrm{w}_{\rho}^{\left(\mathrm{S}_{\mathrm{i}}\right)}\left(\mathrm{k}_{1} \ldots \mathrm{k}_{\ell_{\mathrm{i}}}\right)\right] \tag{3.2}
\end{equation*}
$$

where the functional dependence of $W_{\rho}^{(G)}$ upon $W_{\rho}^{\left(S_{i}\right)}$ is denoted by the square
brackets. We subtract from $W_{\rho}^{\left(S_{i}\right)}$ all terms up to order $d_{i}$ in its Taylor expansion about the point $k_{1}=k_{2}=\cdots=k_{l}=0$. Using (3.1), this gives

$$
\begin{equation*}
W_{\rho}^{(G)}\left[\int_{0}^{1} d \xi_{i} \frac{\left(1-\xi_{i}\right)^{d_{i}}}{d_{i}!}\left(\frac{\partial}{\partial \xi_{i}}\right)^{d_{i}+1} W_{\rho}^{\left(S_{i}\right)}\left(\xi_{i} k_{1}, \ldots \xi_{i} k_{\ell_{i}}\right)\right] \tag{3.3}
\end{equation*}
$$

The steps leading from (2.5) to (2.12) can then be carried out keeping track of the $\xi_{i}$ parameter. This leads to an expression which can be formed from (2.12) by inserting the $\xi_{i}$ parameter into the parametric functions, $U, V, Y_{r}$ and $X_{r s}$ in a simple way and applying the operator

$$
\begin{equation*}
\int_{0}^{1} d \xi_{i} \frac{\left(1-\xi_{i}\right)^{d_{i}}}{d_{i}!}\left(\frac{\partial}{\partial \xi_{i}}\right)^{d_{i}+1} \tag{3.4}
\end{equation*}
$$

to the integrand. Rather than bore the reader with this bookkeeping or even its result, we shall simply present the more general result of the fully renormalized amplitude.

The renormalized amplitude is defined by starting with (2.12) and performing the above operations for a large enough class of subgraphs to insure the convergence of (2.12) in the limit $\rho \rightarrow 0$. Let $\mathscr{S}$ denote the set of proper subgraphs $S_{i}$ of $G$ which
(a) are superficially divergent, $\mathrm{d}_{\mathrm{i}} \geq 0$
(b) cannot be formed from another superficially divergent graph by simply opening one line.
Note that for Quantum Electrodynamics, condition (b) is automatically satisfied by superficially divergent graphs, however, this is not so in general. With each member $\mathrm{S}_{\mathrm{i}}$ of $\mathscr{S}$, we associate a parameter $\xi_{\mathrm{i}}$. If $\mathrm{d}_{\mathrm{G}} \geq 0$, we
let $G=S_{0}$ and associate $\xi_{0}$ with it. Then the renormalized amplitude is

$$
\begin{align*}
& W_{R}^{(G)}=\lim _{\rho \rightarrow 0} W_{R \rho}^{(G)}=\left(\frac{\pi^{2}}{i}\right)^{n} \int_{0}^{\infty} d x_{G} \prod_{S_{i} \in \mathscr{S}} \int_{0}^{1} d \xi_{i} \prod_{S_{j} \in \mathscr{P}} \frac{\left(1-\xi_{j}\right)^{\mathrm{d}}}{\mathrm{~d}_{\mathrm{j}}!}\left(\frac{\partial}{\partial \xi_{j}}\right)^{\mathrm{d}_{\mathrm{j}}+1} . \\
& \times\left.\prod_{r \in G} Z_{r}\left(\frac{1}{i x_{r}} \nabla_{\ell}\right) \frac{1}{\bar{U}^{2}} \exp \left[i\left(\bar{V}+\sum_{r \in G} \hat{x}_{r} \ell_{r} \bar{Y}_{r}-\frac{1}{4} \sum_{r, S \in G} \hat{x}_{r} \hat{x}_{s} \ell_{r} \cdot \ell_{S} \bar{X}_{r s}\right)-i \sum_{r \in G} x_{r}\left(m_{r}^{2}-i \epsilon\right)\right]\right|_{\ell=0} \tag{3.5}
\end{align*}
$$

where $\overline{\mathrm{U}}, \overline{\mathrm{V}}, \overline{\mathrm{Y}}_{\mathrm{r}}, \overline{\mathrm{X}}_{\mathrm{rs}}$ and $\hat{\mathrm{x}}_{\mathrm{r}}$ are defined in the following way:
Def: $\bar{U}$ is formed by multiplying each term in $U$ which is of order $n_{i}+m$ in $\mathrm{x}_{\mathrm{r}}, \mathrm{r} \in \mathrm{S}_{\mathrm{i}}$ by $\xi_{\mathrm{i}}^{2 \mathrm{~m}}$. This is done for each $\mathrm{S}_{\mathrm{i}} \in \mathscr{P}$.
Def: $\bar{W}^{\mathrm{ij}}$ is defined in the same way and then

$$
\begin{equation*}
V=\frac{1}{\bar{U}} \sum_{i>j} \bar{W}^{i j}\left(-k_{i} \cdot k_{j}\right) \tag{3.6}
\end{equation*}
$$

Def: $\overline{\mathrm{U}}_{\mathrm{C}}$ and $\overline{\mathrm{W}}_{\mathrm{C}}^{\mathrm{ij}}$ are also defined in the same way as $\overline{\mathrm{U}}$ and then

$$
\begin{equation*}
\overline{\mathrm{x}}_{\mathrm{rs}}=\frac{1}{\overline{\mathrm{U}}} \sum_{\mathrm{C} \in \mathrm{C}(\mathrm{r}, \mathrm{~s})} \pm \overline{\mathrm{U}}_{\mathrm{C}} \tag{3.7a}
\end{equation*}
$$

and

$$
\begin{equation*}
\overline{\mathrm{Y}}_{r \mu}=\sum_{i=1}^{\ell-1}\left(\frac{1}{\overline{\mathrm{U}}} \sum_{\mathrm{C} \in \mathrm{C}(0, \mathrm{r})} \pm \overline{\mathrm{W}}_{\mathrm{C}}^{i \ell}\right) \mathrm{k}_{i \mu} \tag{3.7b}
\end{equation*}
$$

Def: For each line $r$, denote the subset of $\mathscr{S}$ whose members contain $r$ by $\mathscr{S}_{r}$. Then

$$
\begin{equation*}
\hat{\mathrm{x}}_{\mathrm{r}}=\prod_{\mathrm{S}_{\mathrm{i}} \in \mathscr{P}_{\mathrm{r}}} \xi_{\mathrm{i}} \mathrm{x}_{\mathrm{r}} \tag{3.8}
\end{equation*}
$$

We wish to make several observations concerning the definition (3.5) of the renormalized amplitude. First of all; we note that it is a nonrecursive expression, applicable to arbitrary interactions which is explicitly independent of the choice of independent integration momenta and the routing of external momenta through the graph. It will be shown in the next section that (3.5) is an absolutely convergent integral. The members of $\mathscr{S}$ can be either disjoint, nested or overlapping, however, the ordering of the $\xi$ integrations, both among themselves and relative to the $x$ integrations, is irrelevant. The subtractions in (3.5) have been made at the origin of momentum space. There is no fundamental reason for doing this but such a choice for the subtraction point yields a simple form for the renormalized amplitude. This choice will, of course, necessitate finite renormalizations to insure that propagators have poles on the physical mass shell but will also simplify calculations somewhat since it eliminates infra-red divergence problems. These things will be discussed in Sections V and VI. Finally, we might mention that as far as the parameter $\xi_{0}$ corresponding to the entire graph is concerned, the effect of rules for forming $\bar{U}, \bar{V}, \bar{Y}_{r}, \bar{X}_{r s}$ and $\hat{x}_{r}$ is simply to multiply each external momentum by $\xi_{0}$. This is certainly expected.

When each $\mathrm{Z}_{\mathrm{r}}$ is equal to one, (3.5) simplifies a great deal just as (2.12) simplified to give (2.19). It becomes

$$
\begin{align*}
W_{R}^{(G)}= & \left(\frac{\pi^{2}}{i}\right)^{n} \int_{0}^{\infty} d x_{G} \prod_{S_{i} \in \mathscr{P}} \int_{0}^{1} d \xi_{i} \prod_{S_{j} \in \mathscr{S}} \frac{\left(1-\xi_{j}\right)^{-d_{j}}}{d_{j}!}\left(\frac{\partial}{\partial \xi_{j}}\right)^{d_{j}+1} \\
& \times \frac{1}{\bar{U}^{2}} \operatorname{cxp}\left[i\left(\bar{V}-\sum_{r \in G} x_{r}\left(m_{r}^{2}-i \epsilon\right)\right)\right] \tag{3.9}
\end{align*}
$$

The condition $\mathrm{d}_{\mathrm{i}} \geq 0$ which the members of $\mathscr{P}$ must satisfy is now

$$
\begin{equation*}
\nu_{i}=\frac{d_{i}}{2}=2 n_{i}-N_{i} \geq 0 \tag{3.10}
\end{equation*}
$$

since $z_{r}=0$ for all $r \in G$. Since each $\xi_{i}$ parameter appears only in the form $\xi_{i}^{2}$, the formula

$$
\begin{equation*}
\int_{0}^{1} d x \frac{(1-x)^{2 n}}{2 n!}\left(\frac{\partial}{\partial x}\right)^{2 n+1} f\left(x^{2}\right)=\int_{0}^{1} d y \frac{(1-y)^{n}}{n!}\left(\frac{\partial}{\partial y}\right)^{n+1} f(y) \tag{3.11}
\end{equation*}
$$

can be applied for each $\mathrm{S}_{\mathrm{i}} \in \mathscr{S}$ and using (3.10) we get

$$
\begin{align*}
\mathrm{W}_{\mathrm{R}}^{(\mathrm{G})}= & \left(\frac{\pi^{2}}{i}\right)^{\mathrm{n}_{\mathrm{G}}} \int_{0}^{\infty} \mathrm{dx}{ }_{\mathrm{G}}^{S_{\mathrm{i}} \in \mathscr{P}_{0}} \int_{\mathrm{d}} \int_{S_{j} \in \mathscr{P}}^{1} \frac{\left(1-\xi_{\mathrm{j}}\right)^{\nu}}{\nu_{\mathrm{j}}!}\left(\frac{\partial}{\partial \xi_{\mathrm{j}}}\right)^{\nu_{\mathrm{j}}+1} \\
& \times \frac{1}{\hat{U}^{2}} \exp \left[\mathrm{i} \hat{v}-\mathrm{i} \sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right] . \tag{3.12}
\end{align*}
$$

$\hat{U}$ is defined by multiplying each term in $U$ which is of order $n_{i}+m$ in $x_{r}, r \in S_{i}$ by $\xi_{i}^{m} . \hat{W}^{i j}$ is defined in the same way and then $\hat{V}$ is given by

$$
\begin{equation*}
\hat{\mathrm{V}}=\frac{1}{\hat{\mathrm{U}}} \sum_{\mathrm{i}>\mathrm{j}}^{\ell} \hat{\mathrm{w}}^{\mathrm{ij}}\left(-\mathrm{k}_{\mathrm{i}} \cdot \mathrm{k}_{\mathrm{j}}\right) \tag{3.13}
\end{equation*}
$$

The $\xi$ operations were constructed to produce subtractions at the origin of momentum space. To see how this works in the parametric form, we consider the simple case of a graph $G$ for which each $Z_{r}$ is equal to one and for which $\mathscr{T}$ contains only one member $S$ with $\nu_{S}=0$. Then the regularized
renormalized amplitude is

$$
\begin{align*}
& \mathrm{W}_{\mathrm{Rp}}^{(\mathrm{G})}=\left(\frac{\pi^{2}}{\mathrm{i}}\right)^{\mathrm{n}} \int_{\rho}^{\infty} \mathrm{dx}_{\mathrm{G}} \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{1}{\hat{U}_{\mathrm{G}}^{2}} \exp \left[\mathrm{i} \hat{\mathrm{~V}}_{\mathrm{G}}-1 \sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right] \\
&=\left(\frac{\pi^{2}}{\mathrm{i}}\right)^{\mathrm{n}}{ }^{\mathrm{G}} \int_{\rho}^{\infty} \mathrm{dx}_{\mathrm{G}}\left\{\frac{1}{\hat{U}_{\mathrm{G}}^{2}(\xi=1)} \exp \left[\mathrm{i} \hat{\mathrm{~V}}_{\mathrm{G}}(\xi=1)-\mathrm{i} \sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{r}^{2}-\mathrm{i} \epsilon\right)\right]\right.  \tag{3.14}\\
&\left.-\frac{1}{\hat{U}_{\mathrm{G}}^{2}(\xi=1)} \exp \left[\mathrm{i} \hat{\mathrm{~V}}_{\mathrm{G}}(\xi=0)-\mathrm{i} \sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right]\right\}
\end{align*}
$$

The G subscript has been-included on the parametric functions. Clearly

$$
\begin{equation*}
\hat{\mathrm{U}}_{\mathrm{G}}(\xi=1)=\mathrm{U}_{\mathrm{G}} \tag{3.15a}
\end{equation*}
$$

and

$$
\begin{equation*}
\hat{\mathrm{V}}_{\mathrm{G}}(\xi=1)=\mathrm{V}_{\mathrm{G}} . \tag{3.15b}
\end{equation*}
$$

From the definitions of $\hat{\mathrm{U}}_{\mathrm{G}}$ and $\hat{\mathrm{V}}_{\mathrm{G}}$ and Eqs. (2.20) and (2.21), we have

$$
\begin{equation*}
\hat{\mathrm{U}}_{\mathrm{G}}(\xi=0)=\mathrm{U}_{\mathrm{S}} \mathrm{U}_{\mathrm{R}} \tag{3.16a}
\end{equation*}
$$

and

$$
\begin{equation*}
\hat{\mathrm{V}}_{\mathrm{G}}(\xi=0)=\mathrm{V}_{\mathrm{R}} \tag{3.16b}
\end{equation*}
$$

where $R$ is the graph formed from $G$ by shrinking each line of $S$ to a point. Using' (3.15) and (3.16), expression (3.14) becomes

$$
\begin{aligned}
W_{R \rho}^{(G)} & =w_{\rho}^{(G)}\left\{\left(\frac{\pi^{2}}{i}\right)^{n} S \int_{\rho}^{\infty} d x_{S} \frac{1}{U_{S}^{2}} \exp \left[-i \sum_{r \in S} \dot{x}_{r}\left(m_{r}^{2}-i \epsilon\right)\right]\right\} \\
& \times\left\{\left(\frac{\pi^{2}}{i}\right)^{n}{ }^{R} \int_{\rho}^{\infty} d x_{R} \frac{1}{U_{R}^{2}} \exp \left[i V_{R}-i \sum_{r \in R} x_{r}^{\left(m_{r}^{2}-i \epsilon\right)}\right]\right\} \\
= & W_{\rho}^{(G)}-W_{\rho}^{(S)}(0) w_{\rho}^{(R)}
\end{aligned}
$$

as expected.
IV. Finiteness of the Renormalized Amplitude

The renormalized amplitude is defined in Section III by using the subtraction operator (3.4). In order to prove that it is a well-defined expression, we will carry out the derivatives appearing in the subtraction operators and then investigate the remaining integral over the x and $\xi$ parameters. In order to keep things as simple as possible, we will restrict ourselves to the case of spin zero propagators and no derivative couplings for which the renormalized amplitude is given by (3.12).

The result of doing the $\xi$-derivatives in (3.12) is an expression of the form

$$
\begin{equation*}
\int_{0}^{\infty} d x_{G} \int_{0}^{1} \prod_{S_{i} \in \mathscr{S}} d \xi_{i} \sum_{\sigma} S_{\sigma}(k) \frac{R_{\sigma}(x, \xi)}{\hat{U}^{2+} p_{\sigma}} \exp \left[i \hat{V}-i \sum_{r \in G} x_{r}\left(m_{r}^{2}-i \epsilon\right)\right] \tag{4.1}
\end{equation*}
$$

where the summation is over the terms generated by carrying out the derivative operators. $S_{\sigma}(k)$ depends only upon the invariants formed from the external momenta and $R_{\sigma}(x, \xi)$ is a produce of $x_{r}{ }^{\prime} \mathrm{s}$ and $\xi_{i}{ }^{\prime} \mathrm{s}$. The integrand of (4.1) decreases exponentially at infinity and the only possible poles occur at the zeros of $\hat{U}$. From its definition, we know that

$$
\begin{equation*}
\hat{\mathrm{U}} \geq 0 \tag{4.2}
\end{equation*}
$$

and that it vanishes only when some subset of the $x_{r}$ 's and $\xi_{i}$ 's is set equal to zero. Let H be a collection of lines in the graph G under consideration with $\mathrm{N}_{\mathrm{H}}$ members and let $\mathscr{S}^{\prime}$ be a subset of $\mathscr{S}$ with $\mathrm{S}^{\prime}$ members. Let $\mathrm{n}\left(\mathscr{S}^{\prime}, \mathrm{H}\right),\left(\mathrm{m}_{\sigma}\left(\mathscr{P}^{\prime}, \mathrm{H}\right)\right)$ denote the order of the zero of $\hat{\mathrm{U}},\left(\mathrm{R}_{\sigma}(\mathrm{x}, \xi)\right)$ when
$\mathrm{X}_{\mathrm{r}}=0, \mathrm{r} \in \mathrm{H}$ and $\xi_{\mathrm{i}}=0, \mathrm{~S}_{\mathrm{i}} \in \mathscr{F}^{\prime}$. Then in order to show that (4.1) is welldefined, it is sufficient to show that for any H , any $\mathscr{P}$ ? and any term in the sum over $\sigma$,

$$
\begin{equation*}
\mathrm{N}_{\mathrm{H}}+\mathrm{S}^{\prime}+\mathrm{m}_{\sigma}\left(\mathscr{F}^{\prime}, \mathrm{H}\right)>\mathrm{n}\left(\mathscr{P}^{\prime}, \mathrm{H}\right)\left(\mathrm{p}_{\sigma}+2\right) \tag{4.3}
\end{equation*}
$$

We first consider the zeros of $\hat{\mathrm{U}}$. When $\mathscr{P}^{\prime}$ is empty, $\mathrm{n}\left(\mathscr{S}^{\prime}, \mathrm{H}\right)$ is given simply by $n_{H}$. This follows from the properties of the parametric functions listed in Section II. When $\mathscr{S}^{\prime}$ is not empty, the situation becomes substantially more complicated and the general result is given by the following theorem.

Theorem 1: Let $\mathscr{P}^{\prime}=\left\{\mathrm{S}_{1}, \mathrm{~S}_{2}, \ldots \mathrm{~S}_{\mathrm{S}^{\prime}}\right\}$. These graphs may overlap in various ways and we construct from them a sequence of nested sets of lines. We define $S(i)$ to be the set of lines in $G$ which belong to at least i members of $\left\{S_{1}, S_{2}, \ldots S_{S^{\prime}}\right\}$. Then $S\left(S^{\prime}\right) \subset S\left(S^{\prime}-1\right) \subset \ldots \subset S(1) \subset S(0) \equiv G$. We define $R(i)$ to be the set of lines formed from $S(i)$ by shrinking all the lines of $S(i+1)$ to a point and $\dot{n}_{H \cap R(i)}$ to be the number of independent closed loops formed by. the lines of H in $\mathrm{R}(\mathrm{i})$. Then

$$
\begin{equation*}
\mathrm{n}\left(\mathscr{P}^{\prime}, \mathrm{H}\right)=\mathrm{n}_{\mathrm{H} \cap \mathrm{R}\left(\mathrm{~S}^{\prime}\right)}+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}\left(\mathrm{~S}^{\prime}-1\right)}+\ldots \mathrm{n}_{\mathrm{H} \cap \mathrm{R}(1)}+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}(0)}+\ell_{\mathscr{P}} \tag{4.4}
\end{equation*}
$$

where

$$
\begin{equation*}
\ell_{\mathscr{P}^{\prime}}=\sum_{i=1}^{S^{\prime}} \mathrm{n}_{\mathrm{S}(\mathrm{i})}-\sum_{\mathrm{j}=1}^{\mathrm{S}^{\prime}} \mathrm{n}_{\mathrm{S}_{\mathrm{i}}} \tag{4.5}
\end{equation*}
$$

This theorem will be proved in Appendix A. The desired result (4.3) will then follow from the next theorem concerning the zeros of $R_{\sigma}(x, \xi)$ which will also be proved in Appendix A.

Theorem 2: For any term in the sum over $\sigma$,
$m_{\sigma}\left(\mathscr{P}^{\prime}, \mathrm{H}\right)>\left[\mathrm{n}_{\mathrm{H} \cap \mathrm{R}\left(\mathrm{S}^{\prime}\right)}+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}\left(\mathrm{S}^{\prime}-1\right)}+\ldots+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}(0)}+\ell_{\mathscr{P}^{\prime}}\right]\left(\mathrm{p}_{\sigma}+2\right)-\mathrm{N}_{\mathrm{H}}-\mathrm{S}^{\prime}$

The general proofs of these theorems are somewhat tedious and it would probably be helpful to first look at a simple example. We consider the graph of Figure 3 which arises in the $\phi^{4}$ theory.

Vertex graph in the $\phi^{4}$ theory with overlapping vertex subgraphs.
Figure 3

The set $\mathscr{S}$ contains four members; the entire graph $\mathrm{S}_{0}$, the graph $\mathrm{S}_{1}$ consisting of lines $1,2,3$ and 4 , the graph $\mathrm{S}_{2}$ consisting of lines $3,4,5$ and 6 , and the graph $S_{3}$ consisting of lines 3 and 4 . For each of these, $\nu_{i}=0$ and the renormalized amplitude is given by

$$
\begin{align*}
&\left(\frac{\pi^{2}}{i}\right)^{3} \int_{0}^{\infty} d_{x_{1}} \ldots d_{x_{6}} \int_{0}^{1} d \xi_{0} \ldots d \xi \prod_{i=0}^{3} \frac{\partial}{\partial \xi_{k}} \frac{1}{\hat{U}^{2}} \times \\
& \times \exp \left[i \frac{\hat{W}}{\hat{U}}\left(k_{1}+k_{2}\right)^{2}-i\left(m^{2}-i \epsilon\right)\left(x_{1}+\ldots+x_{6}\right)\right] \tag{4.7}
\end{align*}
$$

where

$$
\begin{equation*}
\hat{\mathrm{U}}=\left[\xi_{3} \xi_{1} \mathrm{x}_{3} \mathrm{x}_{4}\left(\mathrm{x}_{1}+\mathrm{x}_{2}\right)+\xi_{2} \mathrm{x}_{3} \mathrm{x}_{4}\left(\mathrm{x}_{5}+\mathrm{x}_{6}\right)\right]+\left(\mathrm{x}_{3}+\mathrm{x}_{4}\right)\left(\mathrm{x}_{1}+\mathrm{x}_{2}\right)\left(\mathrm{x}_{5}+\mathrm{x}_{6}\right) \tag{4.8a}
\end{equation*}
$$

$$
\begin{align*}
\hat{\mathrm{w}}= & \xi_{0} \xi_{3} \mathrm{x}_{3} \mathrm{x}_{4}\left[\xi_{1}^{2} \mathrm{x}_{1} \mathrm{x}_{2}+\xi_{1} \xi_{2}\left(\mathrm{x}_{1} \mathrm{x}_{6}+\mathrm{x}_{2} \dot{\mathrm{x}}_{5}\right)+\xi_{2}^{2} \mathrm{x}_{5} \mathrm{x}_{6}\right] \\
& +\xi_{0}\left(\mathrm{x}_{3}+\mathrm{x}_{4}\right)\left[\xi_{1} \mathrm{x}_{1} \mathrm{x}_{2}\left(\mathrm{x}_{5}+\mathrm{x}_{6}\right)+\xi_{2} \mathrm{x}_{5} \mathrm{x}_{6}\left(\mathrm{x}_{1}+\mathrm{x}_{2}\right)\right] \tag{4.8b}
\end{align*}
$$

Suppose that $H$ consists of lines 5 and 6 and $\mathscr{P}^{\prime}$ consists of one member $S_{1}$.
Then $\ell_{\mathscr{P}^{\prime}}=0, R(0)=G / S_{1}$ and

$$
\begin{equation*}
\mathrm{n}\left(\mathscr{S}^{\prime}, \mathrm{H}\right)=\mathrm{n}_{\mathrm{H} \cap \mathrm{R}(0)}=1 \tag{4.9}
\end{equation*}
$$

In addition, $\mathrm{N}_{\mathrm{H}}=2$ and $\mathrm{S}^{\prime}=1$ and by inspection, one can see that the condition of Theorem 2,

$$
\begin{equation*}
\mathrm{m}_{\sigma}\left(\mathscr{S}^{\prime}, \mathrm{H}\right)>\left(\mathrm{P}_{\sigma}+2\right)-3 \tag{4.10}
\end{equation*}
$$

holds for each tern in the sum over $\sigma$.

Finally, we wish to briefly discuss the limit $\epsilon \rightarrow+0$ in (3.12). To do.this, we transform it-into the Feynman denominator form. This is done by inserting the factor

$$
\int_{0}^{\infty} \frac{\dot{d} \lambda}{\lambda} \delta\left(1-\frac{1}{\lambda} \sum_{r \in G} \mathbf{x}_{r}\right)=1
$$

into (3.12), rescaling $x_{r} \rightarrow \lambda x_{r}$ for all $r \in G$ and doing the $\lambda$ integration. For the case $2 n_{G}-N_{G}<0$, the result is

$$
\begin{align*}
\mathrm{w}_{\mathrm{R}}^{(\mathrm{G})} \sim & \int_{0}^{\infty} \mathrm{dx}_{\mathrm{G}} \delta\left(1-\sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\right) \prod_{\mathrm{S}_{\mathrm{i}} \in \mathscr{S}} \int_{0}^{1}{\mathrm{~d} \xi_{\mathrm{i}}}^{\prod_{\mathrm{j}} \in \mathscr{S}} \prod_{\mathrm{j}} \frac{\left(1-\xi_{\mathrm{j}}\right)^{\nu}}{\nu_{\mathrm{j}}!}\left(\frac{\partial}{\partial \xi_{\mathrm{j}}}\right)^{\nu_{\mathrm{j}}+1}  \tag{4.11}\\
& \times \frac{1}{\hat{\mathrm{U}}^{2}} \frac{1}{\left[\hat{\mathrm{~V}}-\sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right]} \mathrm{N}_{\mathrm{G}}-2 \mathrm{n}_{\mathrm{G}}
\end{align*}
$$

In the limit $\epsilon \rightarrow+0, \mathrm{~W}_{\mathrm{R}}^{(\mathrm{G})}$ will have singularities determined by the zeros of $\hat{V}-\sum_{r \in G} x_{r} m_{r}^{2}$. These singularities correspond to the existence of absorptive parts due to the opening up of inelastic channels. The usual treatment (2) (6) of these singularities for unrenormalized amplitudes, leading to the Landau conditions (10), can be carried over directly to the renormalized amplitude (4.11). For a careful treatment of the $\epsilon \rightarrow 0$ limit using the language of distribution theory, we refer the reader to the paper of Hepp (9).

- The proof that the renormalized amplitude is well-defined can easily be generalized to the case of an arbitrary Feynman amplitude given by (3.5). Onc ain carries out the $\xi$ derivatives and examines each term
generated by these operations. From the form of the functions $U, V ; Y_{r}$ and $X_{r s}$, it is clear that the effect of the derivative operators is again to make the integral "less divergent" and the proof, although somewhat more complicated, goes through just as above.

## V. Mass and Coupling Constant Renormalization

We have given a prescription for associating a well-defined renormalized amplitude with an arbitrary Feynman graph. The usual method of defining renormalized amplitudes is by means of a recursive subtraction formula of the type used by Salam (11) and more recently by Bogoluibov and Parasiuk (1) and Hepp (9). In this section we intend to show the formal equivalence of our subtraction scheme with a recursive subtraction formula in which the subtraction terms can be related to Lagrangian counter-terms and hence to field, coupling constant and mass renormalizations. These renormalization effects are usually dealt with via the Green's functions of the theory, however, the Lagrangian counter-term approach seems to be simpler for our purposes. We will restrict ourselves to the $\phi^{4}$ theory in this discussion however it applies to any renormalizable theory. We have not, as yet, been able to completely prove that our prescription is equivalent to a recursive subtraction formula for an arbitrary unrenormalizable theory although we feel that this is the case.

We first consider briefly some of the features of the $\phi^{4}$ theory. The Lagrangian density for this theory written in terms of unrenormalized quantities is

$$
\begin{equation*}
\dot{\mathscr{L}}(\mathrm{x})=\frac{1}{2}\left(\partial_{\mu} \phi_{0} \partial^{\mu} \phi_{0}-\mathrm{m}_{0}^{2} \phi_{0}^{2}\right)-\frac{1}{4!} \lambda_{0} \phi^{4} \tag{5.1}
\end{equation*}
$$

We introduce a new mass, coupling constant and field as follows:

$$
\begin{align*}
m_{0}^{2} & =m^{2}+\delta m^{2}  \tag{5.2a}\\
\phi_{0} & =z_{2}^{\frac{1}{2}} \phi \tag{5.2~b}
\end{align*}
$$

$$
\begin{equation*}
\lambda_{0}=\frac{\dot{z}_{1}}{\mathrm{z}_{2}^{2}} \lambda \tag{5.2c}
\end{equation*}
$$

Then letting

$$
\begin{equation*}
z_{2}=1+B \quad Z_{1}=1-L \tag{5.3}
\end{equation*}
$$

$\mathscr{L}(\mathrm{x})$ can be written as
$\mathscr{L}(\mathrm{x})=\frac{1}{2}\left(\partial_{\mu} \phi \partial^{\mu} \phi-\mathrm{m}^{2} \phi^{2}\right)-\frac{1}{4} \lambda \phi^{4}-\frac{1}{2} \mathrm{Z}_{2} \delta \mathrm{~m}^{2} \phi^{2}+\frac{1}{2} \mathrm{~B}\left(\partial_{\mu} \phi \partial^{\mu} \phi-\mathrm{m}^{2} \phi^{2}\right)+\mathrm{L} \frac{1}{4!} \lambda \phi^{4}$

We next carry through the canonical formalism and construct the interaction Hamiltonian in the interaction representation. The result is
$\mathscr{H}_{\mathrm{I}}(\mathrm{x})=\frac{1}{4!} \lambda \phi_{\mathrm{I}}^{4}-\mathrm{L} \frac{1}{4!} \lambda \phi_{\mathrm{I}}^{4}+\frac{1}{2} \delta \mathrm{~m}^{2} \mathrm{Z}_{2} \phi_{\mathrm{I}}^{2}-\frac{1}{2} \mathrm{~B}\left(\partial_{\mu} \phi_{\mathrm{I}} \partial^{\mu} \phi_{\mathrm{I}}-\mathrm{m}^{2} \phi_{\mathrm{I}}^{2}+\frac{1}{2} \frac{\mathrm{~B}^{2}}{1+\mathrm{B}} \dot{\phi}_{\mathrm{I}}^{2}\right.$,
or letting

$$
\begin{gather*}
\mathrm{A}=-\delta \mathrm{m}^{2} \mathrm{Z}_{2}-\mathrm{Bm}^{2}  \tag{5.6}\\
\mathscr{H}_{\mathrm{I}}(\mathrm{x})=\frac{1}{4!} \lambda \phi_{\mathrm{I}}^{4}-\mathrm{L} \frac{1}{4!} \lambda \phi_{\mathrm{I}}^{4}-\frac{1}{2} \mathrm{~A} \phi_{\mathrm{I}}^{2}-\frac{1}{2} \mathrm{~B} \partial_{\mu} \phi_{\mathrm{I}} \partial^{\mu} \phi_{\mathrm{I}}+\frac{1}{2} \frac{\mathrm{~B}^{2}}{1+\mathrm{B}} \dot{\phi}_{\mathrm{I}}^{2} . \tag{5.7}
\end{gather*}
$$

In perturbation theory, this interaction Hamiltonian gives rise to the usual four-line vertex coming from the first term as well as several new types of vertices. It is well known (12) that there are only two types of divergences in the graphs arising from the first term in (5.7). These divergences correspond to vertex subgraphs (four external ?) for which
$\nu=0$ and self-energy graphs (two external lines) for which $\nu=1$. The vertex subgraphs can overlap as in the graph of Figure 3.. The second term in $\mathscr{H}(\mathrm{x})$ gives rise to four-line vertices which serve as counter-terms for the vertex subgraphs while the noxt two terms which produce two-line vertices are the counter-terms necessary to remove the divergences corresponding to selfenergy subgraphs. The last term in $\mathscr{H}(x)$ serves to cancel the non-covariant contributions coming from the next to last term due to the fact that the derivative operator does not commute with the time-ordering operator.

The effect of these counter-terms in $\mathscr{H}_{\mathrm{I}}(\mathrm{x})$ is that all graphs arising from them can be forgotten provided that for any graph $G$ arising from the first term in $\mathscr{H}_{\mathrm{I}}(\mathrm{x})$, the corresponding unsubtracted amplitude $\mathrm{W}^{(\mathrm{G})}$ is replaced by a renormalized amplitude $\mathrm{W}_{\mathrm{R}}^{(\mathrm{G})}$ which we are about to define. Let $\left\{\mathrm{S}_{1} \ldots \mathrm{~S}_{\mathrm{m}}\right\}$ be any set of mutually disjoint vertex and self-energy subgraphs of a given graph G. We denote the functional dependence of $W^{(G)}$ upon $w^{\left(S_{1}\right)} \ldots W^{\left(S_{m}\right)}{ }_{b y}$

$$
\begin{equation*}
W^{(G)}=W^{\left(G / S_{1} \ldots S_{m}\right)}\left[W^{\left(S_{1}\right)} \ldots W^{\left(S_{m}\right)}\right] \tag{5.8}
\end{equation*}
$$

Everything is assumed to be regularized in some consistent manner in this discussion. We then define a quantity $\bar{W}^{(G)}$ recursively by

$$
\begin{equation*}
\bar{W}^{(G)}=W^{(G)}+\sum_{\left\{S_{1} \ldots S_{m}\right\}} W^{\left(G / S_{1} \ldots S_{m}\right)}\left[-t \bar{W}^{\left(S_{1}\right)} \ldots-t \bar{W}^{\left.\left(S_{m}\right)\right]}\right. \tag{5.9}
\end{equation*}
$$

where the summation is over all non-empty sets of mutually disjoint vertex and self-energy subgraphs. The regularized amplitudes $\overline{\mathrm{W}}{ }^{\left(\mathrm{S}_{\mathrm{i}}\right)}$ depend upon
the invariants formed from the external momenta. The effect of the operator $t$ is to project out terms up to order $\nu_{i}$ in the Taylor expansion of these ampli tudes about the origin in their invariants. For a vertex subgraph, which depends upon six invariants,

$$
\begin{equation*}
t \bar{\Lambda}^{\left(\mathrm{S}_{\mathrm{i}}\right)}=\bar{\Lambda}^{\left(\mathrm{S}_{\mathrm{i}}\right)}(\text { all invs. }=0)=-i \lambda L^{\left(\mathrm{S}_{\mathrm{i}}\right)} \tag{5.10a}
\end{equation*}
$$

and for a self-energy subgraph

$$
\begin{equation*}
t \bar{\Sigma}^{\left(S_{i}\right)}\left(k^{2}\right)=\bar{\Sigma}^{\left(S_{i}\right)}(0)+\bar{\Sigma}^{\prime}{ }^{\left(S_{i}\right)}(0) k^{2}=A^{\left(S_{i}\right)}+B_{i}^{\left(S_{i}\right)} k^{2} \tag{5.10b}
\end{equation*}
$$

Then $W_{R}^{(G)}$ is given by

$$
\begin{equation*}
\mathrm{W}_{\mathrm{R}}^{(\mathrm{G})}=(1-\mathrm{t}) \overline{\mathrm{W}}^{(\mathrm{G})} \tag{5.11a}
\end{equation*}
$$

if $G$ is a self-energy or vertex graph and

$$
\begin{equation*}
\mathrm{W}_{\mathrm{R}}^{(\mathrm{G})}=\overline{\mathrm{W}}^{(\mathrm{G})} \tag{5.11b}
\end{equation*}
$$

otherwise. The constants in (5.10a) and (5.10b) are related to those in the interaction Hamiltonian (5.7) by

$$
\begin{equation*}
A=\sum_{G} A^{(G)} \quad B=\sum_{G} B^{(G)} \tag{5.12}
\end{equation*}
$$

where the summation is over all proper self-energy graphs and

$$
\begin{equation*}
L=\sum_{G} L^{(G)} \tag{5.13}
\end{equation*}
$$

where the summation is over all proper vertex graphs.
...This connection between subtractions for Feynman graphs and Lagrangian counter-terms is well-known (13) and we do not intend to discuss it further. It is our purpose to show that $W_{R}^{(\mathrm{C})}$ as defincd by (3.12) is cquivalent to the definition given by (5.9) and (5.11) in this chapter. Before proceeding to this, we should point out that since we have made all subtractions at the origin of momentum space, it is necessary to perform additional finite subtractions for self-energy parts to insure that the renormalized propagator will have a pole on the physical mass shell. These finite mass renormalizations are discussed in detail by Yennie and Kuo (7) and a method of performing the subtractions directly on the mass shell is given by the present author in reference (14). This question shall not concern us further.

The proof that (3.12) is equivalent to the definition of $W_{R}^{(G)}$ given in this chapter is straightforward. The operator

$$
\begin{equation*}
\int_{0}^{1} \mathrm{~d} \xi_{i} \frac{\left(1-\xi_{i}\right)^{\nu}}{\nu_{i}!}\left(\frac{\partial}{\partial \xi_{i}}\right)^{\nu_{i}+1} \tag{5.14}
\end{equation*}
$$

appearing in (3.12) is, through relation (3.1), equivalent to the operator (1-t) used in this chapter. Thus

$$
\begin{equation*}
\int_{0}^{1} d \xi_{i} \frac{\left(1-\xi_{i}\right)^{\nu}}{\nu_{i}!}\left(\frac{\partial}{\partial \xi_{i}}\right)^{\nu_{i}+1} f\left(\xi_{i}\right)=f(1)-\sum_{n=0}^{\nu_{i}} \frac{\xi_{i}^{n}}{n!} f^{(n)}(0)=\left(1-t_{i}\right) f\left(\xi_{i}\right) \tag{5.15}
\end{equation*}
$$

where the 1 in $1-t_{i}$ is really an operator which sets $\xi_{i}=1$. We first consider the subset $\mathscr{S}_{0}$ of $\mathscr{P}$ whose members do not properly contain members of $\mathscr{S}$
themselves. We can use the representation (5.15) for the $\xi$ operations corresponding to the members of $\mathscr{S}_{0}$ and if it can be shown that $\mathrm{t}_{\mathrm{i}} \mathrm{t}_{\mathrm{j}}$ vanishes in (3.12) whenever $S_{i} \in \mathscr{S}_{0}$ and $S_{j} \in \mathscr{S}_{0}$ overlap, then (3.12) takes the following form.

$$
\begin{align*}
\mathrm{w}_{\mathrm{R}}^{(\mathrm{G})}= & \left(\frac{\pi^{2}}{\mathrm{i}}\right)^{\mathrm{n}} \mathrm{G} \int_{0}^{\infty} \mathrm{dx}_{\mathrm{G}} \prod_{\mathrm{S}_{\mathrm{i}} \in \mathscr{S}-\mathscr{P}_{0}} \int_{0}^{1} \mathrm{~d} \xi_{\mathrm{i}} \prod_{S_{\mathrm{j}} \in \mathscr{S}-\mathscr{P}_{0}} \frac{\left(1-\xi_{\mathrm{j}}\right)^{\nu}}{\nu_{\mathrm{j}}!}\left(\frac{\partial}{\partial \xi_{\mathrm{j}}}\right)^{\nu_{\mathrm{j}}+1} \\
& \times\left\{1+\sum_{\left\{\mathrm{S}_{1} \cdots \mathrm{~S}_{\mathrm{m}}\right\} \in \mathscr{P}_{0}}\left(-t_{1}\right) \ldots\left(-\mathrm{t}_{\mathrm{m}}\right)\right\} \frac{1}{\hat{\mathrm{U}}^{2}} \exp \left[\mathrm{i} \hat{V}-\mathrm{i} \sum_{\mathbf{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right] . \tag{5.16}
\end{align*}
$$

where the summation is over all sets of mutually disjoint members of $\mathscr{P}_{0}$. When a term in this summation does not contain $t_{i}$ where $S_{i} \in \mathscr{S}_{0}$, then $\xi_{i}$ is to be set equal to 1 .

We next consider those members of $\mathscr{P}$ which properly contain only the subgraphs in $\mathscr{S}_{0}$. We again use (5.15) for the $\xi$ operations corresponding to these graphs and we will show that a product of $t$ operators corresponding to two overlapping members of this set gives zero.when in (5.16) due to $\xi$ operations corresponding to the union of these two graphs. This procedure can be continued working from the inside out and the result is that $W_{R}^{(G)}$ becomes

$$
\begin{align*}
\mathrm{W}_{\mathrm{R}}^{(\mathrm{G})}= & \left(\frac{\pi^{2}}{\mathrm{i}}\right)^{\mathrm{n}} \mathrm{G} \int_{0}^{\infty} \mathrm{dx}_{\mathrm{G}}\left\{1+\sum_{\left\{\mathrm{S}_{\mathrm{l}} \ldots \mathrm{~S}_{\mathrm{m}}\right\} \in \mathscr{P}}\left(-\mathrm{t}_{\mathrm{i}}\right) \ldots\left(-\mathrm{t}_{\mathrm{m}}\right)\right\}  \tag{5.17}\\
& \times \frac{1}{\hat{U}^{2}} \exp \left[\mathrm{i} \hat{\mathrm{~V}}-\mathrm{i} \sum_{\mathrm{r} \in \mathrm{G}} \mathrm{x}_{\mathrm{r}}\left(\mathrm{~m}_{\mathrm{r}}^{2}-\mathrm{i} \epsilon\right)\right] .
\end{align*}
$$

The summation is over all non-empty sets $\left\{S_{1} \ldots S_{m}\right\}$ of non-overlapping members of $\mathscr{P}$. Note that members of $\left\{\mathrm{S}_{1} \ldots \mathrm{~S}_{\mathrm{m}}\right\}$ may be nested. In order to show that (5.17) is equivalent to the definition of $W_{R}^{(G)}$ given by (5.9) and (5.11), we re-arrange the sumruation in (5.17) by defining an operator $Q_{G}$ recursively by

$$
\begin{equation*}
Q_{G}=\left\{1+\sum_{\left\{S_{1} \cdots S_{m}\right\}}\left(-t_{i} Q_{S_{i}}\right) \cdots\left(-t_{m} Q_{S_{m}}\right)\right\}, \tag{5.18}
\end{equation*}
$$

the sum being over all non-empty sets of mutually disjoint members of $\mathscr{P}$ which are properly contained in G. Then

$$
\begin{equation*}
W_{R}^{(G)}=\left(\frac{\pi^{2}}{i}\right)^{n} \int_{0}^{\infty} \int_{0}^{\infty} x_{G}\left(1-t_{0}\right) Q_{G} \frac{1}{\hat{U}^{2}} \exp \left[i \hat{V}-i \sum_{r \in G} x_{r}\left(m_{r}^{2}-i \epsilon\right)\right] \tag{5.19}
\end{equation*}
$$

where $t_{0}=0$ for $\nu_{0}=\nu_{G}<0$. The reader can easily convince himself by inspection that (5.19) is identical to (5.17). The equivalence of (5.19) with the definition of $W_{R}^{(G)}$ via (5.9) and (5.11) should be clear since these two expressions have the same form. Regularization is not necessary in (5.19) since the subtraction operations are performed directly on the integrand.

It remains to prove that the overlaps do indeed vanish as we have stated above. We have shown in reference (14) that if two members $\mathrm{S}_{\mathrm{a}}$ and $\mathrm{S}_{\mathrm{b}}$ of $\mathscr{S}$ overlap, then they must both be vertex subgraphs and $\mathrm{S}_{\mathrm{a}} \cup \mathrm{S}_{\mathrm{b}}$ must be either a self-energy or vertex subgraph. If $\mathrm{S}_{\mathrm{a}} \cup \mathrm{S}_{\mathrm{b}} \in \mathscr{P}$, we let $S_{c}=S_{a} \cup S_{b}$. If $S_{a} \cup S_{b}$ is a vertex subgraph which is not an element of $\mathscr{P}$, we let $S_{c}$ be the self-energy subgraph formed from $S_{a} \cup S_{b}$ by adjoining one line. Thus the vertex subgraph of Figure 4 composed of lines 1 to 6 is not a
member of $\mathscr{S}$ but the self-energy graph formed by adjoining line 7 is a member of $\mathscr{P}$.

A graph with a superficially divergent subgraph which is not a member of $\mathscr{P}$.

Figure 4

In either of the above cases, $\mathrm{S}_{\mathrm{c}} \in \mathscr{S}$ and hence there will be a $\xi$ operadion corresponding to this graph. The operation $t_{a} t_{\mathrm{b}}$ simply sets $\xi_{\mathrm{a}}$ and $\xi_{\mathrm{b}}$ equal to zero. Since $\hat{U}$ does not have a zero when $\xi_{\mathrm{a}}=\xi_{\mathrm{b}}=0$, the $\mathrm{t}_{\mathrm{a}} \mathrm{t}_{\mathrm{b}}$ operation can be commuted with the $\xi$ derivatives and what we must show is that

$$
\begin{equation*}
\left(\frac{\partial}{\partial \xi_{c}}\right)^{c^{+1}} \frac{1}{\hat{U}^{2}\left(\xi_{a}=\xi_{b}=0\right)} \exp \left[i \hat{\nabla}\left(\xi_{a}=\xi_{b}=0\right)-\sum_{r \in G} x_{r}\left(m_{r}^{2}-i \epsilon\right)\right]=0 \tag{5.20}
\end{equation*}
$$

Consider any term in $\hat{U}$ or $\hat{W}^{i j}$ which contain a factor $\xi_{c}$. This term must be at least of order $n_{S_{c}}+1$ in $x_{r}, r \in S_{c}$ and hence at least of order $n_{S_{a}} \cup S_{b}+1$ in $x_{r}, r \in S_{a} \cup S_{b}$. Suppose that it is of order $n_{S_{a}}+m_{a},\left(n_{S_{b}}+m_{b}\right)$ in $x_{r}, r \in S_{a},\left(S_{b}\right)$. Then since any term is at least of order $n_{S_{a} \cap S_{b}}$ in $x_{r}, r \in S_{a} \cap S_{b}$,

$$
\begin{equation*}
\mathrm{n}_{\mathrm{S}_{\mathrm{a}} \cup \mathrm{~S}_{\mathrm{b}}}<\mathrm{n}_{\mathrm{S}_{\mathrm{a}}}+\mathrm{m}_{\mathrm{a}}+\mathrm{n}_{\mathrm{S}_{\mathrm{b}}}+\mathrm{m}_{\mathrm{b}}-\mathrm{n}_{\mathrm{S}_{\mathrm{a}} \cap \mathrm{~S}_{\mathrm{b}}} \tag{5.21}
\end{equation*}
$$

## But clearly

$$
\begin{equation*}
n_{S_{a} \cup S_{b}}=n_{S_{a}}+n_{S_{b}}-n_{S_{a} \cap S_{b}} \tag{5.22}
\end{equation*}
$$

for two overlapping vertex graphs and hence

$$
\begin{equation*}
m_{a}+m_{b}>0 \tag{5.23}
\end{equation*}
$$

This means that any term in U or $\mathrm{W}^{\mathrm{ij}}$ which contains a factor $\xi_{\mathrm{c}}$ must also contain either a factor $\xi_{\mathrm{a}}$ or $\xi_{\mathrm{b}}$. Thus all dependence on $\xi_{\mathrm{c}}$ vanishes when $\xi_{\mathrm{a}}$ and $\xi_{\mathrm{b}}$ are set equal to zero. This gives the result (5.20).

## VI. Fourth Order Vacuum Polarization

The starting point for any calculation in quantum electrodynamics is expression (3.5) with vertex $\gamma$-matrices, constant factors and traces over closed fermion loops inserted. To illustrate the technique, we first look at the second order vacuum polarization.

Second order vacuum polarization graph.

Figure 5

The unsubtracted amplitude is

$$
\begin{equation*}
\Pi_{\mu \nu O}^{(2)}(\mathrm{k})=\frac{\alpha}{4 \pi^{3}} \int \mathrm{~d}^{4} \mathrm{p} \mathrm{~T}_{\mathrm{r}}\left\{\gamma_{\mu} \frac{\mathrm{i}}{\not p+\mathrm{k}-\mathrm{m}} \gamma_{\nu} \frac{\mathrm{i}}{\not p-\mathrm{m}}\right\} \tag{6.1}
\end{equation*}
$$

where $\alpha$ is the fine structure constant. According to (3.5), the corresponding renormalized amplitude is

$$
\begin{align*}
\Pi_{\mu \nu}^{(2)}(\mathrm{k})= & \frac{\alpha}{4 \pi^{3} \mathrm{i}}\left(\frac{\pi^{2}}{\mathrm{i}}\right) \int_{0}^{\infty} \mathrm{dx}_{1} \mathrm{dx} \int_{2} \int_{0}^{1} \mathrm{~d} \xi \frac{(\mathrm{l}-\xi)^{2}}{2!}\left(\frac{\xi}{\partial \xi}\right)^{3} \frac{1}{\left(\mathrm{x}_{1}+\mathrm{x}_{2}\right)^{2}} \\
& \times \mathrm{T}_{\mathrm{r}}\left\{\gamma_{\mu}\left(\frac{\mathrm{x}_{1}}{\mathrm{x}_{1}+\mathrm{x}_{2}} \xi k \quad \operatorname{l} \nu_{\nu}\left(\frac{-\mathrm{x}_{2}}{\mathrm{x}_{1}+\mathrm{x}_{2}} \xi k+\mathrm{m}\right)+\frac{1}{2} \frac{1}{\mathrm{x}_{1}+\mathrm{x}_{2}} \gamma_{\mu} \gamma^{\sigma} \gamma_{\nu} \gamma_{\sigma}\right\}\right.  \tag{6.2}\\
& \left.\times \exp \left[\mathrm{i} \frac{\mathrm{x}_{1} \mathrm{x}_{2}}{\mathrm{x}_{1}+\mathrm{x}_{2}} \xi^{2} \mathrm{k}^{\sigma} \quad \mathrm{I}_{2}+\mathrm{x}_{2}\right) \mathrm{m}^{2}\right]
\end{align*}
$$

where $\mathrm{m}^{2}$ includes a small negative imaginary part. Since $\Pi_{\mu \nu}(\mathrm{k})$ is gauge invariant, it must be of the form

$$
\begin{equation*}
\Pi_{\mu \nu}(\mathrm{k})=\left(\mathrm{g}_{\mu \nu} \mathrm{k}^{2}-\mathrm{k}_{\mu} \mathrm{k}_{\nu}\right) \Pi(\mathrm{k}) \tag{6.3}
\end{equation*}
$$

Thus doing the trace in (6.2) and extracting the coefficient of $-\mathrm{k}_{\mu} \mathrm{k}_{\nu}$ gives $\Pi^{(2)}(\mathrm{k})$.

$$
\begin{align*}
\Pi^{(2)}(\mathrm{k})= & -\frac{2 \alpha}{\pi} \int_{0}^{\infty} d x_{1} d x_{2} \int_{0}^{1} d \xi \frac{(1-\xi)^{2}}{2!}\left(\frac{\partial}{\partial \xi}\right)^{3} \xi^{2} \frac{x_{1} x_{2}}{\left(x_{1}+x_{2}\right)^{4}} \\
& \times \exp \left[i \frac{x_{1} x_{2}}{x_{1}+x_{2}} \xi^{2} k^{2}-i m^{2}\left(x_{1}+x_{2}\right)\right] \tag{6.4}
\end{align*}
$$

Inserting the identity

$$
\begin{equation*}
1=\int_{0}^{\infty} \frac{d \lambda}{\lambda} \delta\left(1-\frac{1}{\lambda} \sum_{r \in G} x_{r}\right) \tag{6.5}
\end{equation*}
$$

scaling $\mathrm{x}_{\mathrm{r}} \rightarrow \lambda \mathrm{x}_{\mathrm{r}}$ and doing the $\xi$ integral gives
$m^{(2)}(\mathrm{k})=-\frac{2 \alpha}{\pi} \int_{0}^{1} \mathrm{dxx}(1-\mathrm{x}) \int_{0}^{\infty} \frac{\mathrm{d} \lambda}{\lambda}\left\{\exp \left[i \lambda x(1-\mathrm{x}) \mathrm{k}^{2}-\mathrm{i} \lambda \mathrm{m}^{2}\right]-\exp \left[-\mathrm{i} \lambda \mathrm{m}^{2}\right]\right\}$

Using the identity

$$
\begin{equation*}
\int_{0}^{\infty} \frac{d \lambda}{\lambda}\left(e^{i a \lambda}-e^{i b \lambda}\right)=\log \left(\frac{b}{a}\right) \tag{6.7}
\end{equation*}
$$

we have

$$
\begin{equation*}
\mathrm{n}^{(2)}(\mathrm{k})=\frac{2 \alpha}{\pi} \int_{0}^{1} \mathrm{dxx}(1-\mathrm{x}) \log \left(1-\mathrm{x}(1-\mathrm{x}) \frac{\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right) \tag{6.8}
\end{equation*}
$$

which for $-k^{2} / m^{2} \gg 1$ becomes

$$
\begin{equation*}
\frac{\alpha}{3 \pi} \log \left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right)-\frac{5}{9} \frac{\alpha}{\pi} \tag{6.9}
\end{equation*}
$$

The fourth order vacuum polarization ${ }^{I 1}{ }_{\mu \nu}^{\left(\frac{1}{2}\right)}$ consists of contributions from the three diagrams of Figure 6.

(a)

(b)

(c)

Fourth order vacuum polarization graphs.

Figure 6

The contributions from graphs 6 b and 6 c are identical and hence

$$
\begin{equation*}
\Pi_{\mu \nu}^{(4)}(\mathrm{k})=\left(\mathrm{g}_{\mu \nu} \mathrm{k}^{2}-\mathrm{k}_{\mu} \mathrm{k}_{\nu}\right) \Pi^{(4)}(\mathrm{k})=\Pi_{\mu \nu}^{(\mathrm{a})}(\mathrm{k})+2 \Pi_{\mu \nu}^{(\mathrm{b})}(\mathrm{k}) \tag{6.10}
\end{equation*}
$$

where $\Pi_{\mu \nu}^{(\mathrm{a})}(\mathrm{k})$ and $\Pi_{\mu \nu}^{(\mathrm{b})}(\mathrm{k})$ are the amplitudes corresponding to graphs 6 a and 6b, respectively. For the graph of Figure 6a, the set $\mathscr{P}$ in (3.5) consists of the entire graph and the two overlapping vertex graphs composed of lines $1,4,5$ and $2,3,5$. We assoc iate the parameter $\xi_{0}$ with the entire graph, the parameter $\xi_{1}$ with the $1,4,5$ vertex and the parameter $\xi_{2}$ with the $2,3,5$ vertex. Then defining parametric functions $\bar{U}_{a}, \bar{W}_{\mathrm{a}}, \overline{\mathrm{Y}}_{\mathrm{ra}}$ and $\overline{\mathrm{X}}_{\mathrm{rsa}}$ according
to the rules of. Section III and introducing the notation

$$
\begin{equation*}
\int_{0}^{1} d \xi_{i} \frac{\left(1-\xi_{i}\right)^{n}}{n!}\left(\frac{\partial}{\partial \xi_{i}}\right)^{n+1}=R_{i}^{(n+1)} \tag{6.11}
\end{equation*}
$$

we have

$$
\begin{aligned}
& \Pi_{\mu \nu}^{(\mathrm{a})}(\mathrm{k})=\mathrm{i}\left(\frac{\alpha}{4 \pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}, \ldots, \mathrm{dx} \mathrm{x}_{1} \mathrm{R}_{0}^{(3)} \mathrm{R}_{1}^{(1)} \mathrm{R}_{2}^{(1)}
\end{aligned}
$$

$$
\begin{aligned}
& \times\left.\exp \left[i\left(\frac{\bar{W}_{a}}{\bar{U}_{a}} k^{2}+\sum_{r=1}^{4} x_{r} \ell_{r} \cdot \bar{Y}_{r a}-\frac{1}{4} \sum_{r, s=1}^{4} x_{r} x_{s} \ell_{r} \cdot \ell_{s} \bar{X}_{r s a}\right)-i m^{2} \sum_{r=1}^{4} x_{r}-\epsilon x_{5}\right]\right|_{\ell_{r}=0}
\end{aligned}
$$

To form $\Pi_{\mu \nu}^{(\mathrm{b})}(\mathrm{k})$, we first apply the rules of Section III which effect subtractions at the origin of momentum space. The result will be a contribution similar to (6.12). In order to insure that the second order electron propagator composed of lines $1,2,3$ and 5 has a simple pole at $k=m$, we must subtract from this contribution a term in which the second order renormalized .electron self energy $\Sigma^{(2)}(k)$ is replaced by $\Sigma^{(2)}(k=m)$. Associating the parameter $\xi_{0}$ with the entire graph and the parameter $\xi_{1}$ with the self energy subgraph composed of lines 2 and 5 , we have

$$
\begin{align*}
& \Pi_{\mu \nu}^{(\mathrm{b})}(\mathrm{k})=\mathrm{i}\left(\frac{\alpha}{4 \pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}_{1}, \ldots, \mathrm{dx}_{5} \mathrm{R}_{0}^{(3)} \mathrm{R}_{1}^{(2)} \\
& \times \operatorname{Tr}\left\{\gamma_{\mu}\left(\frac{1}{\mathrm{ix}} \ddot{X}_{l_{1}}+\mathrm{m}\right) \gamma_{\sigma}\left(\frac{1}{\mathrm{ix}_{2}} \not \ddot{Z}_{l_{2}}+\mathrm{m}\right) \gamma_{\sigma}\left(\frac{1}{\mathrm{ix}_{3}} \not \ddot{\nabla}_{l_{3}}+\mathrm{m}\right) \gamma_{\nu}\left(\frac{1}{\mathrm{ix}} \ddot{Y}_{4}+\mathrm{m}\right)\right\} \frac{1}{U_{2}^{2}}  \tag{6.12}\\
& \times\left.\exp \left[i\left(\frac{\bar{W}_{b}}{\bar{U}_{b}} k^{2}+\sum_{r=1}^{4} x_{r} \ell_{r} \cdot \bar{Y}_{r b}-\frac{1}{4} \sum_{r, s=1}^{4} \hat{x}_{r} \hat{x}_{s} \ell_{r} \cdot \ell_{s} \bar{X}_{r s b}\right)-i m^{2} \sum_{r=1}^{4} x_{r}-\epsilon x_{5}\right]\right|_{\ell_{r}=0} \\
& -\Sigma^{(2)}(\mathrm{m}) \Pi_{\mu \nu}^{(\mathrm{R})}(\mathrm{k})
\end{align*}
$$

$$
\begin{align*}
\Pi^{(a)}(\mathrm{k})= & 2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}_{1} \ldots \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1} \ldots-\mathrm{x}_{5}\right) \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{1}{\hat{\mathrm{U}}_{\mathrm{a}}^{2}} \\
& \times\left\{\left[\xi \frac{x_{5}}{\hat{U}_{\mathrm{a}}}\left(\mathrm{~A}_{1} \mathrm{~A}_{2}-\hat{\mathrm{A}}_{1} \hat{A}_{4}\right)-\frac{\mathrm{x}_{1}+\mathrm{x}_{4}}{\hat{U}_{\mathrm{a}}} \mathrm{~A}_{1} \mathrm{~A}_{4}\right] \log \left(1-\frac{\mathrm{k}^{2}}{\mathrm{~m}^{2}} \frac{\hat{\mathrm{~W}}_{\mathrm{a}}}{\hat{U}_{\mathrm{a}}\left(\mathrm{x}_{1}+\ldots+\mathrm{x}_{4}\right)}\right)\right.  \tag{6.15}\\
& \left.+\frac{1}{\left(\mathrm{x}_{1}+\cdots+\mathrm{x}_{4}\right)}\left[\xi \mathrm{A}_{2}\left(\mathrm{~A}_{1}+\mathrm{A}_{4}\right)-\hat{A}_{1} \hat{A}_{4}\right]\left(1-\frac{\mathrm{m}^{2}}{\mathrm{k}^{2}} \frac{\left(\mathrm{x}_{1}+\ldots+\mathrm{x}_{4}\right) \hat{\mathrm{U}}_{a}}{\hat{\mathrm{~W}}_{\mathrm{a}}}\right)^{-1}\right\}
\end{align*}
$$

where

$$
\begin{align*}
& \hat{U}_{a}=\left(x_{1}+x_{4}\right)\left(x_{2}+x_{3}+x_{5}\right)+\xi x_{5}\left(x_{2}+x_{3}\right) \\
& \hat{W}_{a}=x_{1} x_{4}\left(x_{2}+x_{3}+x_{5}\right)+\xi x_{2} x_{3}\left(x_{1}+x_{4}+\xi x_{5}\right)+\xi x_{5}\left(x_{1} x_{3}+x_{2} x_{4}\right)  \tag{6.16a}\\
& A_{1}=\frac{1}{\hat{U}_{a}}\left[x_{4}\left(x_{2}+x_{3}+x_{5}\right)+\xi x_{3} x_{5}\right] \\
& \hat{A}_{4}=-\frac{1}{\hat{U}_{a}}\left[x_{1}\left(x_{2}+x_{3}+x_{5}\right)+\xi x_{2} x_{5}\right]  \tag{6.16b}\\
& A_{2}=\frac{1}{U_{a}}\left[x_{1} x_{3}+x_{3} x_{4}+x_{3} x_{5}+x_{4} x_{5}\right]
\end{align*}
$$

and where $U_{a}, W_{a}, A_{1}$ and $A_{4}$ are formed by setting $\xi=1$ in $\hat{U}_{a}, \hat{W}_{a}, \hat{A}_{1}$ and $\hat{A}_{4}$ respectively and

$$
\begin{align*}
& 2 \Pi^{(\mathrm{b})}(\mathrm{k})=2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}_{1} \ldots \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\ldots-\mathrm{x}_{5}\right) \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} . \\
& \times\left\{\left[\frac{x_{4}^{2} x_{5}\left(x_{2}+x_{r}\right)^{2}}{\hat{U}_{b}^{5}}-3 \hat{B}_{4} \frac{x_{4} x_{5}\left(x_{2}+x_{5}\right)}{\hat{U}_{b}^{4}}\right] \log \left(1-\frac{k^{2}}{m^{2}} \frac{\hat{W}_{b}}{\hat{U}_{b}\left(x_{1}+\cdots+x_{4}\right)}\right)\right. \\
& +\int_{0}^{1} d \xi_{0} \frac{\partial}{\partial \xi_{0}} \hat{B}_{4}\left[\xi_{0} \mathrm{k}^{2} \frac{\mathrm{x}_{4}^{3} \mathrm{x}_{5}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)^{2}}{\hat{\mathrm{U}}_{\mathrm{b}}^{5}}-\mathrm{m}^{2} \mathrm{x}_{4} \frac{4 \mathrm{x}_{2}+3 \mathrm{x}_{5}}{\hat{\mathrm{U}}_{\mathrm{b}}^{3}}\right]  \tag{6.17}\\
& \left.\times\left(\frac{\hat{W}_{b}}{\hat{U}_{b}} \xi 0^{2}-m^{2}\left(x_{1}+\cdots+x_{1}\right)\right)^{-1}\right\}-2 \Sigma^{(2)}(m) \Pi^{(R)}(k)
\end{align*}
$$

where

$$
\begin{align*}
& \hat{\mathrm{U}}_{\mathrm{b}}=\left(\mathrm{x}_{1}+\mathrm{x}_{3}+\mathrm{x}_{4}\right)\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)+\xi \mathrm{x}_{2} \mathrm{x}_{5} \\
& \hat{\mathrm{w}}_{\mathrm{b}}=\mathrm{x}_{4}\left(\mathrm{x}_{1}+\mathrm{x}_{3}\right)\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)+\xi \mathrm{x}_{2} \mathrm{x}_{4} \mathrm{x}_{5}  \tag{6.18}\\
& \hat{\mathrm{~B}}_{4}=\frac{1}{\mathrm{U}_{\mathrm{b}}}\left[\left(\mathrm{x}_{1}+\mathrm{x}_{3}\right)\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)+\xi \mathrm{x}_{2} \mathrm{x}_{5}\right] .
\end{align*}
$$

We now restrict our attention to the asymptotic region $-k^{2} \gg \mathrm{~m}^{2}$ and keep only those terms in $\Pi^{(a)}(\mathrm{k})$ and $\Pi^{(\mathrm{b})}(\mathrm{k})$ which behave like $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ or $\log ^{2}\left(-k^{2} / m^{2}\right)$ in this region. $\Pi^{(a)}(k)$ becomes

$$
\begin{equation*}
\Pi^{(a)}(k)=\Pi_{1}^{(a)}(k)+\Pi_{2}^{(a)}(k)+\Pi_{3}^{(a)}(k) \tag{6.19}
\end{equation*}
$$

where $\Pi_{1}^{(a)}(k)$ comes from those terms multiplying the $\log$ in (6.15) which do not require the internal subtraction (those containing a factor of $\xi$ or $\xi^{2}$ ).

For these terms, the log can be expanded and

$$
\begin{align*}
\Pi_{1}^{(a)}(k)= & 2\left(\frac{\alpha}{\pi}\right)^{2} \log \left(\frac{-k^{2}}{m^{2}}\right) \int_{0}^{\infty} d x_{1} \ldots d x_{5} \frac{1}{U_{a}^{3}}\left\{x_{5}\left(A_{1} A_{2}-A_{1} A_{4}\right)\right. \\
& \left.+\left(x_{1}+x_{4}\right) \frac{1}{U_{a}^{2}}\left[x_{5}\left(x_{2}+x_{3}+x_{5}\right)\left(x_{1} x_{3}+x_{2} x_{4}\right)+x_{2} x_{3} x_{5}^{2}\right]\right\} \tag{6.20}
\end{align*}
$$

$\Pi_{2}^{(a)}(k)$ comes from that term multiplying the log which does require the internal subtraction. For this term, the log cannot be expanded since this would introduce a logarithmic divergence in $x_{1}, x_{4}$ and $\xi$.

$$
\begin{align*}
\Pi_{2}^{(a)}(\mathrm{k})= & 2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}_{1} \ldots \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1} \cdots-\mathrm{x}_{5}\right) \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{1}{\hat{\theta}_{a}^{5}} \\
& \times\left(\mathrm{x}_{1}+\mathrm{x}_{4}\right) \mathrm{x}_{1} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{3}+\mathrm{x}_{5}\right)^{2} \log \left(1-\frac{\mathrm{k}^{2}}{\mathrm{~m}^{2}} \frac{\hat{\mathrm{w}}_{\mathrm{a}}}{\hat{0}_{\mathrm{a}}\left(\mathrm{x}_{1}+\ldots+\mathrm{x}_{4}\right)}\right) \tag{6.21}
\end{align*}
$$

Since the log serves as a cutoff for a logarithmically divergent integral, we expect $\mathrm{II}_{2}^{(\mathrm{a})}(\mathrm{k})$ to give a $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contribution. The remaining terms in (6.15) are convergent without the internal subtraction, however, there is one non-vanishing subtraction term ( $\xi=0$ term). It is only for this term, $\Pi_{3}^{(a)}(k)$, that the limit $-k^{2} / m^{2} \rightarrow \infty$ is not finite.

$$
\begin{align*}
\mathrm{H}_{3}^{(a)}(\mathrm{k})= & -2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{\infty} d x_{1} \ldots d x_{5} \delta\left(1-x_{1}-\ldots-x_{5}\right) \frac{x_{1} x_{4}}{\left(x_{1}+x_{4}\right)^{4}\left(x_{2}+x_{3}+x_{5}\right)^{2}\left(x_{1}+\ldots+x_{4}\right)} \\
& \times\left(1-\frac{m^{2}}{k^{2}} \frac{\left(x_{1}+\ldots+x_{4}\right)\left(x_{1}+x_{4}\right)}{x_{1} x_{4}}\right)^{-1} \tag{6.22}
\end{align*}
$$

This integral diverges logarithmically when $-\mathrm{k}^{2} / \mathrm{m}^{2} \rightarrow \infty$ and hence it will give a $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contribution.

Similarly,

$$
\begin{equation*}
2 \Pi^{(\mathrm{b})}(\mathrm{k})=\Pi_{1}^{(\mathrm{b})}(\mathrm{k})+\Pi_{2}^{(\mathrm{b})}(\mathrm{k})+\Pi_{3}^{(\mathrm{b})}(\mathrm{k}) \tag{6.23}
\end{equation*}
$$

where $\Pi_{1}^{(\mathrm{b})}(\mathrm{k})$ comes from the term multiplying the log in (6.17) for which the subtraction term $(\xi=0$ term $)$ vanishes. The log can be expanded and
$\Pi_{1}^{(b)}(\mathrm{k})=-6\left(\frac{\alpha}{\pi}\right)^{2} \log \left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right) \int_{0}^{\infty} d x_{1} \ldots d x_{5} \delta\left(1-\mathrm{x}_{1}-\ldots-\mathrm{x}_{5}\right) \frac{\mathrm{x}_{2} \mathrm{x}_{4} \mathrm{x}_{5}^{2}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)}{\mathrm{U}_{\mathrm{b}}^{5}}$.
$\Pi_{2}^{(b)}$ comes from those terms multiplying the $\log$ in (6.17) which require the internal subtraction. Expanding the log would produce a logarithmic divergence for these terms in $\mathrm{x}_{\mathrm{l}}, \mathrm{x}_{2}, \mathrm{x}_{4}$ and $\xi$ and so we expect a $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contribution.
$\mathrm{II}_{2}^{(\mathrm{b})}(\mathrm{k})=-2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}_{1} \ldots \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\ldots-\mathrm{x}_{5}\right) \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{1}{\hat{U}_{b}^{5}}$

$$
\begin{equation*}
\times x_{4} x_{5}\left(x_{2}+x_{5}\right)^{2}\left(3 x_{1}+3 x_{3}-x_{4}\right) \log \left(1-\frac{\mathrm{k}^{2}}{m^{2}} \frac{\hat{\mathrm{w}}_{\mathrm{b}}}{\hat{\mathrm{U}}_{\mathrm{b}}\left(\mathrm{x}_{1}+\ldots+\mathrm{x}_{4}\right)}\right) \tag{6.25}
\end{equation*}
$$

$\Pi_{3}^{(b)}$ comes from the term in (6.17) with $k^{2}$ in the numerator which requires the internal subtraction.

$$
\begin{align*}
n_{3}^{(b)}(k)= & 2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{\infty} \mathrm{dx}_{1} \ldots \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\cdots-\mathrm{x}_{5}\right) \int_{0}^{1} \mathrm{~d} \xi \cdot \frac{\partial}{\partial \xi} \cdots \\
& \times \frac{\mathrm{x}_{4}^{3} \mathrm{x}_{5}\left(\mathrm{x}_{1}+\mathrm{x}_{3}\right)\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)^{3}}{\hat{U}_{\mathrm{b}}^{6}}\left(\frac{\hat{\mathrm{~W}}_{\mathrm{b}}}{\hat{U}_{\mathrm{b}}}-\frac{\mathrm{m}^{2}}{\mathrm{k}^{2}}\left(\mathrm{x}_{1}+\ldots+\mathrm{x}_{4}\right)\right)^{-1} \tag{6.26}
\end{align*}
$$

When $-\mathrm{k}^{2} / \mathrm{m}^{2} \rightarrow \infty$, this integral diverges logarithmically in $\mathrm{x}_{1}, \mathrm{x}_{3}, \mathrm{x}_{4}$ and $\xi$. Hence we expect it to give a $\log \left(-\mathrm{k}^{2} \cdot / \mathrm{m}^{2}\right)$ contribution. The finite mass counterterm $\Sigma^{(2)}(m) \Pi^{(R)}(k)$ in (6.17) remains finite at $-k^{2} / m^{2} \rightarrow \infty$.

There are six contributions to the asymptotic form of $\Pi^{(4)}(\mathrm{k})$. Four of them, $\Pi_{1}^{(a)}, \Pi_{3}^{(a)}, \Pi_{1}^{(b)}$ and $\Pi_{3}^{(b)}$, give rise to $\log \left(-k^{2} / m^{2}\right)$ contributions while $\Pi_{2}^{(a)}$ and $\Pi_{2}^{(b)}$ both give $r$ ise to $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ and $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contributions. It will be shown in Appendix $B$ that the $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ terms cancel and that $\Pi_{2}^{(a)}+\Pi_{2}^{(b)}$ gives only a $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contribution. The integrals giving rise to $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ contributions are straightforward. The calculations are presented briefly in Appendix B. The results are

$$
\begin{align*}
\Pi_{1}^{(a)} & =5 / 8(\alpha / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)  \tag{6.27a}\\
\Pi_{3}^{(\mathrm{a})} & =-1 / 3(\alpha / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)  \tag{6.27b}\\
\Pi_{1}^{(\mathrm{b})} & =-1 / 8(\alpha / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)  \tag{6.27c}\\
\Pi_{3}^{(\mathrm{b})} & =-1 / 12(\alpha / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)  \tag{6.27d}\\
\Pi_{2}^{(a)}+\Pi_{2}^{(\mathrm{b})} & =1 / 6(\dot{\alpha} / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right) \tag{6.27e}
\end{align*}
$$

The integrations have also been checked numerically (15). Adding these contributions together we have the complete renormalized fourth order vacuum
polarization contribution in the asymptotic region $-\mathrm{k}^{2} \gg \mathrm{~m}^{2}$.

$$
\begin{equation*}
\Pi^{(4)}(\mathrm{k})=1 / 4(\alpha / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right) \tag{6.28}
\end{equation*}
$$

This result for $\mathrm{H}^{(4)}(\mathrm{k})$ is identical to that appearing elsewhere in the literature (5) (6).

## VII. Discussion

The formalism developed here has been shown to be useful from both a formal and practical point of view. It gives a concise way of expressing renormalized amplitudes for arbitrary graphs and the proof of convergence of these integrals is a great deal simpler than the corresponding proof when the renormalized amplitude is given by a recursive subtraction formula. We do not claim great mathematical rigor but the present discussion could be transcribed into a mathematically more precise language without too much difficulty.

From a practical point of view, we feel that this formalism could be very useful especially when combined with numerical integration techniques. For example, the fourth order vacuum polarization is a sum of two parametric integrals, (6.15) and (6.17). These integrals can be done numerically quite easily to give the result (6.28). Several such calculations are being looked into at the present time. A further point of interest is the question of the gauge invariance of the vacuum polarization. A proof of this for the renormalized fourth order amplitude using the parametric formalism is being looked into.

## Acknowledgements

I am indebted to Professor Donald Yennie for many discussions and helpful suggestions during the early part of this work. I also wish to thank Dr. S. Brodsky for a critical reading of the manuscript and Dr. A. Dufner for checking the integrations numerically.

## Appendix A

Two Theorems Concerning the Convergence of the Renormalized Amplitudes

In this appendix we will prove the two theorems which were stated in Section IV.

Proof of Theorem 1: We first consider the nested sequence of sets $S\left(S^{\prime}\right) \subset S\left(S^{\prime}\right) \cup\left[H \cap S\left(S^{\prime}-1\right)\right] \subset S\left(S^{\prime}-1\right) \subset \ldots \subset \subset S(1) \subset S(1) \cup H \subset G . \quad$ For any nested sequence of sets $K_{1}, K_{2} \cdots K_{m}$, it is certainly always possible to choose independent integration momenta such that $n_{K_{i}}$ of the momenta internal to $K_{1}$ are independent and hence there is always at least one term in $\hat{U}$ which is of order $n_{K_{i}}$ in $X_{r}, r \in K_{i}$ for $i=1,2, \ldots, m$. For the above sequence it then follows that this term in $\hat{U}$ will be of order

$$
\begin{equation*}
n_{H \cap R(i)}=n_{S(i+1) \cup[H \cap S(i)]}-n_{S(i+1)} \tag{A.1}
\end{equation*}
$$

in $x_{r}, r \in H \cap R(i)$. It will thus be of order

$$
\mathrm{n}_{\mathrm{H} \cap \mathrm{R}\left(\mathrm{~S}^{\prime}\right)}+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}\left(\mathrm{~S}^{\prime}-1\right)}+\cdots \mathrm{n}_{\mathrm{H} \cap \mathrm{R}(\mathrm{I})}+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}(0)}
$$

in $X_{r}, r \in H$. Suppose that this term is of order $n_{\mathbf{B}_{i}}+m_{i}$ in $X_{r} ; r \in S_{i}$ for $\mathrm{i}=1,2, \ldots, \mathrm{~S}^{\prime}$. It will then be of order $\mathrm{m}_{1}+\mathrm{m}_{2}+\ldots+\mathrm{m}_{\mathrm{S}^{\prime}}$ in $\xi_{1}, \xi_{2}, \ldots, \xi_{S^{\prime}}$. Certainly one restriction on the above numbers is

$$
\begin{equation*}
\sum_{i=1}^{S^{\prime}}\left(n_{S_{i}}+m_{i}\right)=\sum_{j=1}^{S^{\prime}} n_{S(j)} \tag{A.2}
\end{equation*}
$$

## Then defining

$$
\begin{equation*}
\ell_{\mathscr{P}^{\prime}}=\sum_{i=1}^{S^{\prime}} n_{S(i)}-\sum_{i=1}^{S^{\prime}} n_{S_{i}} \tag{A.3}
\end{equation*}
$$

it follows that the term in $\hat{U}$ under consideration is of order

$$
\begin{equation*}
\mathrm{n}_{\mathrm{H} \mathrm{\cap R}\left(\mathrm{~S}^{\prime}\right)}+\mathrm{n}_{\mathrm{H} \mathrm{\cap R}\left(\mathrm{~S}^{\prime}-1\right)}+\ldots+\mathrm{n}_{\mathrm{H} \cap \mathrm{R}(1)}=\mathrm{n}_{\mathrm{H} \cap \mathrm{R}(0)}+\ell_{\mathscr{P}^{\prime}} \tag{A.4}
\end{equation*}
$$

in $\xi_{1}, \xi_{2}, \ldots, \xi_{S}$, and $\mathrm{x}_{\mathrm{r}}, \mathrm{r} \in \mathrm{H}$. A similar analysis shows that any term in $\hat{\mathrm{U}}$ is at least of this order and hence we have the result (4.4) of Theorem 1 .

Proof of Theorem 2: We first prove the useful fact that for any non-empty set $K$ of lines in $G$, the expression $R_{\sigma}(x, \xi)$ appearing in (4.1) is at least of order

$$
\begin{equation*}
n_{K}\left(p_{\sigma}+2\right)-N_{K}+1 \tag{A.5}
\end{equation*}
$$

in $\mathbf{x}_{\mathbf{r}}, \mathbf{r} \in \mathrm{K}$. In this expression, $\mathrm{N}_{\mathrm{K}}$ is the number of lines in K , and $\mathrm{n}_{\mathrm{K}}$ is the number of independent loops formed by these lines. If $\nu_{K}<0$, the proof is trivial since each time a derivative operator in (4.1) acts in such a way as to increase the power $\hat{U}$ in the denominator, it also introduces a term into the numerator which is at least of order $n_{K}$ in $x_{r}, r \in K$. It follows that $\mathrm{R}_{\sigma}(\mathrm{x}, \xi)$ is at least of order $\mathrm{n}_{\mathrm{K}} \mathrm{p}_{\sigma} \geq \mathrm{n}_{\mathrm{K}} \mathrm{p}_{\sigma}+\nu_{\mathrm{K}}+\mathrm{l}=\mathrm{n}_{\mathrm{K}}\left(\mathrm{p}_{\sigma}+2\right)-\mathrm{N}_{\mathrm{K}}+1$ in $X_{r}, r \in K$. Next suppose that $\nu_{K} \geq 0$. For any set $K$ we can associate a member of $\mathscr{S}$ as follows. We first throw out as many lines of K as possible without decreasing the number of independent loops. We assume the resulting set is connected since if it is not we can apply the following considerations to each connected part individually. To this set we add all lines
connecting any two of its vertices. Suppose that there are $\ell$ such lines. Then for the resulting graph $\mathrm{S}(\mathrm{K})$,

$$
\begin{align*}
& n_{S(K)}=n_{K}+\ell  \tag{A.6}\\
& N_{S(K)} \leq N_{K}+\ell \tag{A.7}
\end{align*}
$$

Thus $\nu_{\mathrm{S}(\mathrm{K})} \geq \nu_{\mathrm{K}}+\ell \geq 0$ and hence $\mathrm{S}(\mathrm{K})$ must be a member of $\mathscr{S}$. The $\xi$ operation corresponding to $S(K)$ will insure that $R_{\sigma}(x, \xi)$ is at least of order $\mathrm{n}_{\mathrm{S}(\mathrm{K})} \mathrm{p}_{\sigma}+\nu_{\mathrm{S}(\mathrm{K})}+1$ in $\mathrm{x}_{\mathrm{r}}, \mathrm{r} \in \mathrm{S}(\mathrm{K})$. Thus it is at least of order $\mathrm{n}_{\mathrm{S}(\mathrm{K})} \mathrm{p}_{\sigma}+$ $\nu_{\mathrm{S}(\mathrm{K})}+l-\ell$ in $\mathrm{x}_{\mathrm{r}}, \mathrm{r} \in \mathrm{K}$. But $\nu_{\mathrm{S}(\mathrm{K})}-\ell \geq \nu_{\mathrm{K}}=2 \mathrm{n}_{\mathrm{K}}-\mathrm{N}_{\mathrm{K}}$ and $\mathrm{n}_{\mathrm{S}(\mathrm{K})} \geq \mathrm{n}_{\mathrm{K}}$, and therefore $R_{\sigma}(x, \xi)$ is at least of order $n_{K}\left(p_{\sigma}+2\right)-N_{K}+1$ in $x_{r}, r \in K$.

It follows that $\mathrm{R}_{\sigma}(\mathrm{x}, \xi)$ will be at least of order $\mathrm{n}_{[\mathrm{H} \cap \mathrm{S}(\mathrm{i})] \cup \mathrm{S}(\mathrm{i}+1)}\left(\mathrm{p}_{\sigma}+2\right)$
$-N_{[H \cap S(i)] \cup S(i+1)}+\delta_{i o}$ in $x_{r}, r \in[H \cap S(i)] \cup S(i+1)$. The above condition has been relaxed for all $i$ except $i=0$ to account for the fact that each might be empty. We assume, however, that HUS(1) is not empty. Similarly, $\mathrm{R}_{\sigma}(\mathrm{x}, \xi)$ must be at least of order $n_{S(i)}\left(p_{\sigma}+2\right)-N_{S(i)}+1$ in $x_{r}, r \in S(i)$. Suppose that it is of order $n_{S(i)}\left(p_{\sigma}+2\right)-N_{S(i)}+1+L(i)$ in $x_{r}, r \in S(i)$. Subtracting corresponding terms and using the definition of $R(i)$, we see that $R_{\sigma}(x, \xi)$ must be at least of order
$\left[n_{H \cap R\left(S^{\prime}\right)}+n_{H \cap R\left(S^{\prime}-1\right)}+\ldots+n_{H \cap R(0)}\right]\left(p_{\sigma}+2\right)-N_{H}-S^{\prime}-\sum_{i=1}^{S^{\prime}} L(i)+1$
in $x_{r}, r \in H$. Let $R_{\sigma}(x, \xi)$ be of order $n_{S_{i}}\left(p_{\sigma}+2\right)-N_{S_{i}}+1+L i$ in $X_{r}, r \in S_{i}$. Then clearly

$$
\begin{equation*}
\sum_{i=1}^{S^{\prime}}\left[n_{S_{i}}^{\left(p_{\sigma}+2\right)+N_{S_{i}}+1+L i}\right]=\sum_{j=1}^{S^{\prime}}\left[n_{S(j)}\left(p_{\sigma}+2\right)+N_{S(j)}+1+L(j)\right] . \tag{A.8}
\end{equation*}
$$

From this and the definition (A.3) of $\ell_{\mathscr{S}^{\prime}}$, it follows that $R_{\sigma}(x, \xi)$ is at least of order
$\left[n_{H \cap R\left(S^{\prime}\right)}+\ldots+n_{H \cap R(0)}+\ell_{P^{\prime}}\right]\left(p_{\sigma}+2\right)-N_{H}-S-\sum_{i=1}^{S^{\prime}} L i+l^{i}$
in $X_{r}, r \in H$. Finally we note that $R_{\sigma}(x, \xi)$ must be of order $L i$ in $\xi_{i}$ for $i=1, \ldots, S^{\prime}$. This gives (4.6) and hence Theorem 2 is proven.

## Appendix B

In this appendix we will calculate $\Pi_{1}^{(b)}$ and $\Pi_{3}^{(a)}$ and show that the $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ terms in $\Pi_{2}^{(a)}$ and $\Pi_{2}^{(b)}$ cancel. The other integrals are done in exactly the same way.

We first calculate $\Pi_{1}^{(b)}(\mathrm{k})$. The integral in (6.24) can be made more symmetric and we have

$$
\begin{align*}
\mathrm{H}_{1}^{(\mathrm{b})}(\mathrm{k})= & -\frac{3}{2}\left(\frac{\alpha}{\pi}\right)^{2} \log \left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right) \int_{0}^{1} \mathrm{dx}_{1} \ldots \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\cdots-\mathrm{x}_{5}\right) \\
& \times \frac{\mathrm{x}_{2} \mathrm{x}_{5}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)^{2}\left(\mathrm{x}_{1}+\mathrm{x}_{4}\right)}{\left[\left(\mathrm{x}_{1}+\mathrm{x}_{3}+\mathrm{x}_{4}\right)\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)+\mathrm{x}_{2} \mathrm{x}_{5}\right]} \tag{B.1}
\end{align*}
$$

A convenient substitution of variables is

$$
\begin{align*}
\mathrm{x}_{1} & =\mathrm{uy} & \mathrm{x}_{2} & =\mathrm{vz} \\
\mathrm{x}_{4} & =(\mathrm{l}-\mathrm{u}) \mathrm{y} & \mathrm{x}_{5} & =(1-\mathrm{v}) \mathrm{z}  \tag{B.2}\\
\mathrm{dx}_{1} \mathrm{dx}_{4} & =\mathrm{ydydu} & \mathrm{dx}_{2} \mathrm{dx}_{5} & =\mathrm{zdzdv}
\end{align*}
$$

Then

$$
\begin{array}{rl}
\Pi_{1}^{(b)}(\mathrm{k})= & -\frac{3}{2}\left(\frac{\alpha}{\pi}\right)^{2} \log \left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right) \int_{0}^{1} \mathrm{dx} \\
3 & d y d z d v \delta\left(1-x_{3}-y-z\right)  \tag{B.3}\\
& \times \frac{v(1-v) y^{2}}{\left[y+x_{3}+z v(1-v)\right]}
\end{array}
$$

The change of variables

$$
\begin{align*}
y & =w x \\
x_{3} & =(2 \cdot v) x  \tag{B.4}\\
d y d x_{3} & =x d x d w
\end{align*}
$$

leads to

$$
\begin{equation*}
\Pi_{1}^{(b)}(k)=-\frac{1}{2}\left(\frac{\alpha}{\pi}\right)^{2} \log \left(\frac{-k^{2}}{m^{2}}\right) \int_{0}^{1} d x d v \frac{v(1-v) x^{3}}{[x+(1-x) v(l-v)]^{5}} \tag{B.5}
\end{equation*}
$$

This integral is elementary and yields

$$
\begin{equation*}
\Pi_{1}^{(b)}(k)=-\frac{1}{8}(\alpha / \pi)^{2} \log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right) \tag{B.6}
\end{equation*}
$$

In the integral in the expression (6.22) for $\Pi_{3}^{(a)}$ a variable change of the type (B.2) is also useful. It leads to

$$
\begin{align*}
\Pi_{3}^{(a)}(k)= & -2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{1} d y d z d x_{5} d u \delta\left(1-y-z-x_{5}\right)  \tag{B.7}\\
& \times \frac{u^{2}(1-u)^{2} z}{\left(z+x_{5}\right)(y+z)}\left(y u(1-u)-(y+z) \frac{m^{2}}{k^{2}}\right)^{-1} .
\end{align*}
$$

We next let

$$
\begin{align*}
\mathbf{y} & =w \mathbf{x} \\
\mathbf{z} & =(1-w) \mathbf{x}  \tag{B.8}\\
d y d z & =x d x d w
\end{align*}
$$

and arrive at

$$
\begin{align*}
\Pi_{3}^{(a)}(k)= & -2\left(\frac{\alpha}{\pi}\right)^{2} \log \left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right) \int_{0}^{1} d x d u d w \frac{u^{2}(1-u)^{2}(1-w)}{[1-w x]}\left(w u(1-u)-\frac{m^{2}}{k^{2}}\right)^{-1} \\
= & -2 \frac{\alpha}{\pi} \int_{0}^{2} d u u(1-u) \log \left[1-\frac{\mathrm{k}^{2}}{\mathrm{~m}^{2}} u(1-u)\right] \rightarrow-\frac{1}{3}\left(\frac{\alpha}{\pi}\right)^{2} \ln \left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right)  \tag{B.10}\\
& \\
& \operatorname{as}\left(\frac{-\mathrm{k}^{2}}{\mathrm{~m}^{2}}\right) \rightarrow \infty
\end{align*}
$$

Finally, we will show that $\Pi_{2}^{(a)}+\Pi_{2}^{(b)}$ behaves as $\log \left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ and not $\log ^{2}\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right)$ in the asymptotic region. We first point out that since we are only interested in terms which increase as $\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right) \rightarrow \infty$, the terms containing $\xi$ in $\hat{\mathrm{W}}_{\mathrm{a}}$ in (6.21) and in $\hat{\mathrm{W}}_{\mathrm{b}}$ in (6.25) can be dropped. We show this for (6.25) by rewriting the log appearing there in the form
(B.11)

$$
\log \left(1-\frac{k^{2}}{m^{2}} \frac{x_{4}\left(x_{1}+x_{3}\right)\left(x_{2}+x_{5}\right)}{\hat{U}_{b}\left(x_{1}+\ldots+x_{4}\right)}\right)+\log \left(1+\frac{\xi x_{2} x_{4} x_{5}}{x_{4}\left(x_{1}+x_{3}\right)\left(x_{2}+x_{5}\right)-\frac{m^{2}}{k^{2}} \hat{U}_{b}\left(x_{1}+\ldots+x_{4}\right)}\right)
$$

The limit $\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right) \rightarrow \infty$ can be taken in the second term and the integral (6.25) will still be convergent. Thus only the first term in (B.11) which is formed by dropping terms containing $\xi^{\circ}$ in $\hat{W}_{b}$ contributes in the asymptotic region. A similar result holds for (6.21).

We further simplify ( 6.25 ) by making a change of variables. We let

$$
\begin{equation*}
x_{1} \rightarrow u x_{1}, \quad x_{3} \rightarrow(1-u) x_{1}, \quad d x_{1} d x_{3} \rightarrow x_{1} d x_{1} d y \tag{B.12}
\end{equation*}
$$

with the limits on the $u$ integration being zero and one. The result is

$$
\begin{align*}
\mathrm{H}_{2}^{(\mathrm{b})}(\mathrm{k})= & -2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{1} \mathrm{dx}_{1} \mathrm{dx}_{2} \mathrm{dx}_{4} \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\mathrm{x}_{2}-\mathrm{x}_{4}-\mathrm{x}_{5}\right)  \tag{B.13}\\
& \times \int_{0}^{1} \mathrm{~d} \frac{\partial}{\partial \xi} \frac{\mathrm{x}_{1} \mathrm{x}_{4} \mathrm{x}_{5}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)^{2}\left(3 \mathrm{x}_{1}-\mathrm{x}_{4}\right)}{\hat{\mathrm{U}}^{5}} \log \left(1-\frac{\mathrm{k}^{2}}{\mathrm{~m}^{2}} \frac{\mathrm{x}_{1} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)}{\hat{\mathrm{U}}\left(\mathrm{x}_{1}+\mathrm{x}_{2}+\mathrm{x}_{4}\right)}\right)
\end{align*}
$$

where

$$
\begin{equation*}
\hat{U}=\left(x_{1}+x_{4}\right)\left(x_{2}+x_{5}\right)+\xi x_{2} x_{5} . \tag{B.14}
\end{equation*}
$$

In (6.21) the change of variables

$$
\begin{equation*}
x_{2} \rightarrow u x_{2}, \quad x_{3} \rightarrow(1-u) x_{2}, \quad d x_{2} d x_{3} \rightarrow x_{2} d x_{2} d y \tag{B.15}
\end{equation*}
$$

leads to

$$
\begin{align*}
\Pi_{2}^{(a)}(\mathrm{k})= & 2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{1} \mathrm{dx}_{1} \mathrm{dx}_{2} \mathrm{dx}_{4} \mathrm{dx} x_{5} \delta\left(1-\mathrm{x}_{1}-\mathrm{x}_{2}-\mathrm{x}_{4}-\mathrm{x}_{5}\right)  \tag{B.16}\\
& \times \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{\mathrm{x}_{1} \mathrm{x}_{4} \mathrm{x}_{2}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)^{2}\left(\mathrm{x}_{1}+\mathrm{x}_{4}\right)}{\hat{\mathrm{U}}^{5}} \log \left(1-\frac{\mathrm{k}^{2}}{\mathrm{~m}^{2}} \frac{\mathrm{x}_{1} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)}{\hat{\mathrm{U}}\left(\mathrm{x}_{1}+\mathrm{x}_{2}+\mathrm{x}_{4}\right)}\right)
\end{align*}
$$

From (B.13) and (B.16), we have

$$
\begin{align*}
& \Pi_{2}^{(a)}(\mathrm{k})+\Pi_{2}^{(\mathrm{b})}(\mathrm{k})= 2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{1} \mathrm{dx}_{1} \mathrm{dx}_{2} \mathrm{dx}_{4} \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\mathrm{x}_{2}-\mathrm{x}_{4}-\mathrm{x}_{5}\right) \\
& \times \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{\mathrm{x}_{1} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)}{}{ }^{2}\left[\left(\mathrm{x}_{1}+\mathrm{x}_{4}\right)\left(\mathrm{x}_{2}-\mathrm{x}_{5}\right)-2 \mathrm{x}_{5}\left(\mathrm{x}_{1}-\mathrm{x}_{4}\right)\right]  \tag{B.17}\\
& \hat{U}^{5}
\end{align*}
$$

The second term in the square brackets clearly gives no contribution since $x_{1}$ and $x_{4}$ appear symmetrically everywhere else. The remainder can be written in the form

$$
\begin{gathered}
2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{1} \mathrm{dx}_{1} \mathrm{dx}_{2} \mathrm{dx}_{4} \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\mathrm{x}_{2}-\mathrm{x}_{4}-\mathrm{x}_{5}\right) \\
\times \int_{0}^{1} \mathrm{~d} \xi \frac{\partial}{\partial \xi} \frac{\mathrm{x}_{1} \mathrm{x}_{2} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)^{2}\left(\mathrm{x}_{1}+\mathrm{x}_{4}\right)}{\hat{\mathrm{U}}^{5}} \log \left(\frac{\left.\frac{\mathrm{x}_{1} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)}{\hat{\hat{U}\left(x_{1}+\mathrm{x}_{2}+\mathrm{x}_{4}\right)}-\frac{\mathrm{m}^{2}}{\mathrm{k}^{2}}} \frac{\left(\frac{\mathrm{x}_{1} \mathrm{x}_{4}\left(\mathrm{x}_{2}+\mathrm{x}_{5}\right)}{\hat{\mathrm{U}}\left(\mathrm{x}_{1}+\mathrm{x}_{5}+\mathrm{x}_{4}\right)}-\frac{\mathrm{m}^{2}}{\mathrm{k}^{2}}\right.}{}\right) .}{} .\right.
\end{gathered}
$$

The subtraction is no longer necessary to make this integral convergent in $\mathrm{x}_{2}$ and $\mathrm{x}_{5}$ and we can examine the $\xi=1$ and the $\xi=0$ terms separately. The first is seen to be convergent when $\left(-\mathrm{k}^{2} / \mathrm{m}^{2}\right) \rightarrow \infty$ while the second becomes logarithmically divergent in $x_{1}$ and $x_{4}$ when $\left(-k^{2} / m^{2}\right) \rightarrow \infty$. Thus for $-k^{2} \gg m^{2}$,
$\Pi_{2}^{(a)}(\mathrm{k})+\Pi_{2}^{(\mathrm{b})}(\mathrm{k}) \approx-2\left(\frac{\alpha}{\pi}\right)^{2} \int_{0}^{1} \mathrm{dx}_{1} \mathrm{dx}_{2} \mathrm{dx}_{4} \mathrm{dx}_{5} \delta\left(1-\mathrm{x}_{1}-\mathrm{x}_{2}-\mathrm{x}_{4}-\mathrm{x}_{5}\right)$

$$
\begin{equation*}
\times \frac{x_{1} x_{2} x_{4}}{\left(x_{1}+x_{4}\right)^{4}\left(x_{2}+x_{5}\right)^{3}} \log \left(\frac{\frac{x_{1} x_{4}}{\left(x_{1}+x_{4}\right)\left(x_{1}+x_{4}+x_{2}\right)}-\frac{m^{2}}{k^{2}}}{\frac{x_{1} x_{4}}{\left(x_{1}+x_{4}\right)\left(x_{1}+x_{4}+x_{5}\right)}-\frac{m^{2}}{k^{2}}}\right) \tag{B.19}
\end{equation*}
$$

This integral can be evaluated by the type of variable substitution used above and the result is (6.27e).

## REFERENCES

1. The first attempt at expressing an arbitrary Feynman integral in parametric form seems to be that of Chisolm [Proc. Camb. Phil. Soc. 48, 300 (1952]. These efforts were extended in an effort to prove the divergence of perturbation theory by Hurst [Proc. Roy. Soc. (London) A214, $4 \dot{4}$ (1952) and Proc. Camb. Phil. Soc. 48, 625 (1952)], Thirring [Helv. Phys. Acta 26, 33 (1953)] and Petermann [Helv. Phys. Acta 26, 291 (1953)]. A parametric integral representation for a general Feynman amplitude was first given by Nakanishi [Prog. Theor. Phys. 17, 401 (1957)] in order to prove Dyson's power counting theorem. A related parametric form was used by Nambu [Nuovo Cimento 6, 1064 (1957)] in order to prove a dispersion relation for the vertex function. This work was extended by Symanzik [Prog. Theor. Phys. 20, 690 (1958)]. A more recent application of parametric integral forms of Feynman amplitudes is that of Jaffe [Comm. Math. Phys. 1, 127 (1965)] who again studies the divergence of the perturbation expansion.

8. A similar starting point was used by Bögoliubov and Shirkov [Fortsch. Phys. 4, 438 (1956)]. This renormalization prescription is also presented in N. N. Bogoliubov and D. W. Shirkov, Introduction to the Theory of Quantized Fields (Interscience, New York, 1959). A mathematically rigorous treatment of this approach was begun by Bogoliubov and Parasiuk [Acta Math. 97, 227 (1957)]. Recently, Hepp (see Ref. 9) has given a complete and rigorous presentation of this renormalization prescription.
