1. ABSTRACT

This publication describes and documents the calibration procedure to improve the accuracy (as specified by the manufacturer) of a MITUTOYO C806-10 CMM (Coordinate Measuring Machine) by 50 %. This goal was achieved with the assistance of the PTB (Physikalische Technische Bundesanstalt) in Braunschweig, Germany. The PTB is the equivalent of the NIST in Washington DC.

2. INTRODUCTION

Smaller and therefore cheaper CMMs (Coordinate Measuring Machines) are becoming quite popular. Considering that it has been only a few years since the so-called bench top CMMs first appeared, the number of such units now in the market is quite surprising. For the fiducialization effort of the Final Focus Test Beam (FFTB) electro magnets a CMM was required which could be operated next to the fully powered magnets. A bench top CMM was essential and a MITUTOYO C806-10 was selected.

Although these bench top CMMs provide fairly good measurement results, they are less accurate and less accurately assembled than a first order CMM. A method is suggested by Dr. Trapet¹ to improve the accuracy of CMMs. The PTB developed a software package to determine 22 error parameters of a CMM. These 22 parameters define a column type CMM completely. Unfortunately this software package is still unavailable but an agreement was reached that the PTB will assist us to determine a subset of error parameters. The squareness errors of a CMM usually account for 80% of the error budget. Therefore we decided that six parameters (three squareness and three non-linearity parameters) will be a sufficient number of parameters to be determined for our MITUTOYO C806-10 CMM.

3. CONCEPT OF METHOD

Trapet's method is easy to use and only low priced equipment is needed. It achieves a satisfactory accuracy and facilitates traceability. A pre-calibrated, 2-dimensional object (bore plate) is measured in four defined positions in the working space. The software package derives subsequently from the plate measurements the final parametric errors of the CMM. It is well suited for calibration purposes.

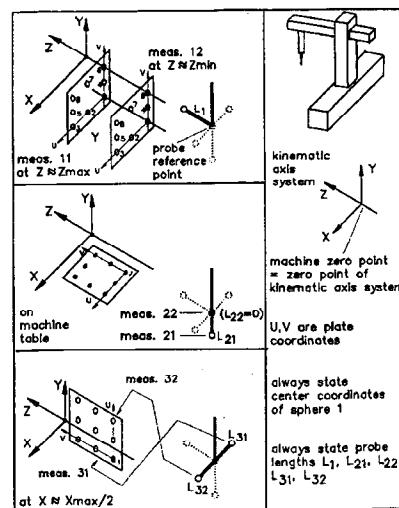

Fig. 1: The 6 plate measurements required for a full error analysis of a column type CMM²

Fig. 1 shows the four plate positions necessary for the reference object, using a bore plate (Fig. 2). With the five different probe styli in Fig. 1 and Fig. 2 the measurements are carried out. By measuring with two central styli (L21 and L22) we have the same effect as measuring once in the lower and once an upper position (positions 21 and 22). In each of the two vertical positions 11 and 12, the plate is measured from one side with stylus L1. The center position between the three long horizontal styli (L1, L31, L32) coincides with the short central stylus L22. The short central stylus L22 represents the reference stylus for which the results (parametric errors) are to be calculated.

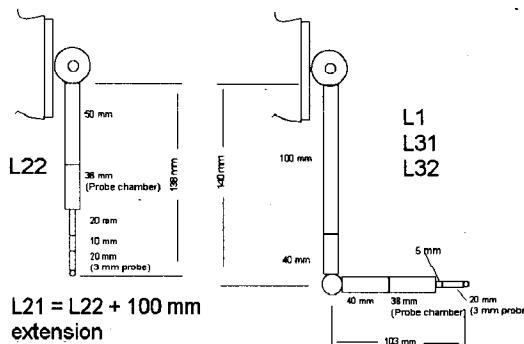

Fig. 2: Probe assemblies for Mitutoyo plate measurements

4. BORE PLATE

The bore plate was designed and manufactured at SLAC (Fig. 3) according to design specifications from the PTB. The material was chosen to be series 6000 aluminum with a temperature expansion coefficient of 23.6×10^{-6} per ${}^{\circ}\text{C}$.

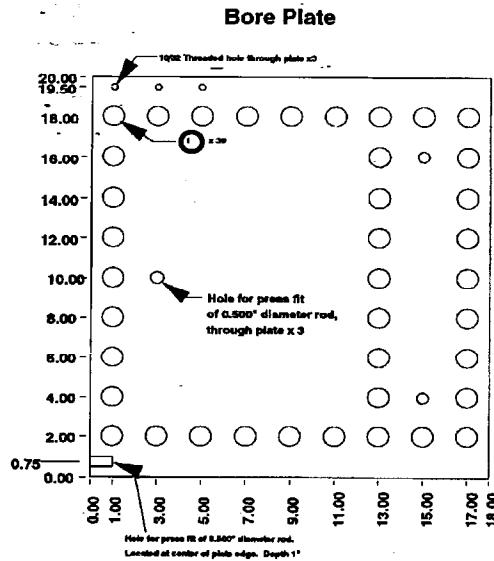

Fig. 3: Bore plate design (all dimensions in inches)

The plate was measured on the LEITZ PM 12106 CMM which is certified for a volumetric accuracy of $0.8\mu\text{m}+2\text{ppm}$. The measurements were performed according to the swing round method (Appendix B), as recommended by the PTB. The plate was measured in all four positions. The temperature at the beginning and at the end of each position was recorded. The average of all four positions reduced to 20°C represented the calibration values.

5. MEASUREMENTS

We chose to evaluate error parameters for 2 areas of the Mitutoyo. The areas were labeled "upstream volume" and "downstream volume". For each position the holes 1 through 32 were measured in the middle of the plate as 2 circles with 4 probings each. The four probings were always in the direction of the coordinate axis. It was chosen to measure in the middle of the plate in order to minimize the effect of a possible bending of the plate. The circles were measured about 1mm vertically separated and all 8 measurements evaluated as cylinders. The cylinder axis was intersected with the plate's symmetry plane going through the center of the plate (top surface offset by half of the plate thickness). The temperature for each plate position was recorded.

6. RESULTS

The plate measurements were evaluated by the PTB in Germany and resulted in following squareness errors in regard to the CMM coordinate system (Fig.4):

| Upstream volume | Downstream volume |
|-----------------|-------------------|
| SQUARE_XY = | SQUARE_XY = |
| -0.000057 [rad] | -0.000087 [rad] |
| SQUARE_XZ = | SQUARE_XZ = |
| 0.000035 [rad] | 0.000049 [rad] |
| SQUARE_YZ= | SQUARE_YZ= |
| 0.000120 [rad] | 0.000121 [rad] |

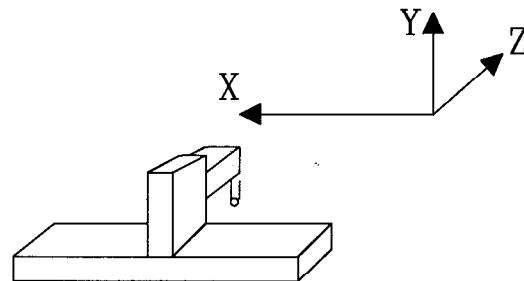

Fig. 4: Mitutoyo calibration coordinate system

The temperature variations during our measurements didn't allow a reliable determination of the scale parameters.

The squareness parameters are applied to the coordinates as follows:

$$\begin{aligned}X_{\text{corrected}} &= X - Y * \text{SQUARE_XY} - Z * \text{SQUARE_XZ} \\Y_{\text{corrected}} &= Y - Z * \text{SQUARE_YZ} \\Z_{\text{corrected}} &= Z\end{aligned}$$

To test our results the above squareness parameters were applied to 6 of the 12 plate measurements for both volumes. We compared the plate coordinates to the calibrated plate values from the LEITZ CMM before and after the corrections were applied (Appendix D). Uncorrected data show discrepancies to the plate calibrations of up to 47 μm . If correction parameters of squareness are applied these discrepancies show as below 15 μm . Additional temperature correction (expansion of scales and expansion of plate) results in values of less than 10 μm by comparing a plate measurement on the MITUTOTO to the plate calibration coordinates (LEITZ CMM). It can be concluded that the application of the squareness

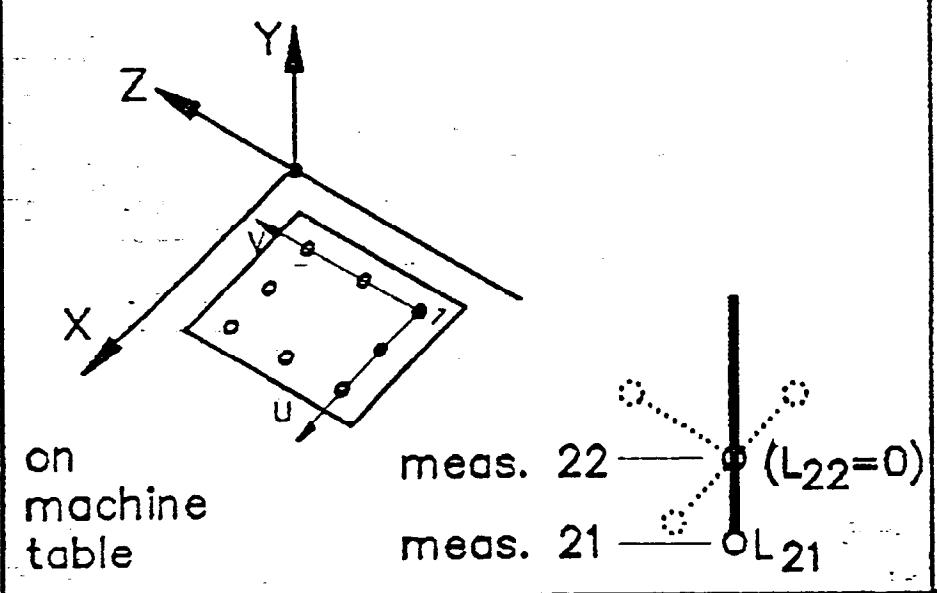

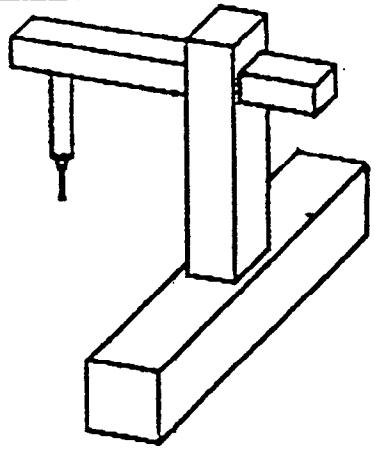

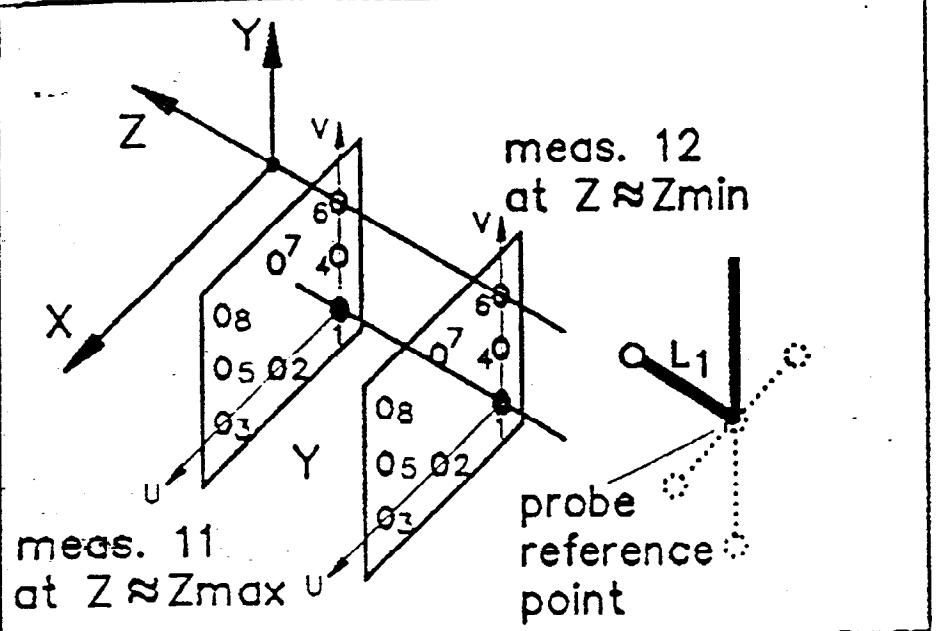

parameters can improve the accuracy of the CMM by at least 50 %. The temperature has to be kept constant at the temperature specified for the machine. A variation of 1°C would result a) in expansion of the CMM scales which could introduce 5 μm on a volume of 400 mm and b) expansion of the material e.g. aluminum 10 μm on a volume of 400 mm. The Mitutoyo is certified by the manufacturer to have a volumetric accuracy of 30 μm +35 ppm. It can be safely stated that with this procedure we improved the accuracy of the CMM by 50%.

7. ACKNOWLEDGMENTS

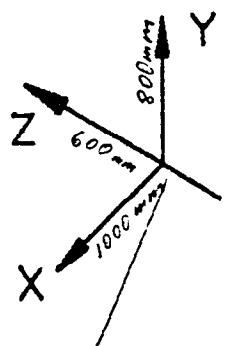

We would like to thank Dr. Trapet from the PTB in Germany for his assistance and help to make this calibration possible. We would also like to acknowledge hereby the contributions of many members of the SLAC staff, in particular B. Wagner who made all the necessary measurements.

FROM: Bernd Wand
DATE: 1-13-92
SUBJECT: Sole source justification for FFTB CMM calibration

The FFTB Coordinate Measurement Machine (CMM) from MITUTOYO doesn't meet the accuracy requirements which are required of FFTB magnet fiducilization application. A procedure developed by the PTB, the German equivalent of our NIST, would allow us to map the error parameters of the CMM like squareness, straightness and linearity of the 3 axis. With those errors mapped it can be expected that we have compensated for ~ 80% of the total error budget. PTB is willing to assist us with this error mapping of the CMM for ~ 6000 DM (~ \$4000). The PTB is the only facility in the world which is capable of rendering this assistance.

Calibration plate for MITUTOYO CMM as measured on the LEITZ CMM (4-17-92)

Plate material: Series 6000 Aluminum
Temperature expansion coefficient: 23.6×10^{-6} / °Celsius

- 1.) Build the plate u,v coordinate system as follows.
 - Origin at hole 1.
 - u-axis defined by hole 1 and hole 9.
 - uv plane defined by symmetry plane parallel to plate's top surface through the center of the plate (offset by half of the plate's thickness).
 - Output the final hole coordinates in this coordinate system.
- 2.) Measure holes in the middle of the plate (eyeballing) as 2 circles with 4 probings each (probings always along coordinate system axis) -> 8 probings total. The 2 circles should be measured ~ 1 mm vertically separated. Evaluate as a cylinder. Intersect its axis with the plate's uv plane which is the symmetry plane parallel to the plate's top surface through the center of the plate (offset by half of the plate's thickness).
- 3.) Always measure in the sequence 1 - 32 clockwise, followed by 33 - 39.
- 4.) Measure the plate in 4 positions as described below. Output the coordinates for each position and the averaged values from all four positions. A total of four coordinate sets.
- 5.) Record temperature at the beginning and at the end of the measurements.

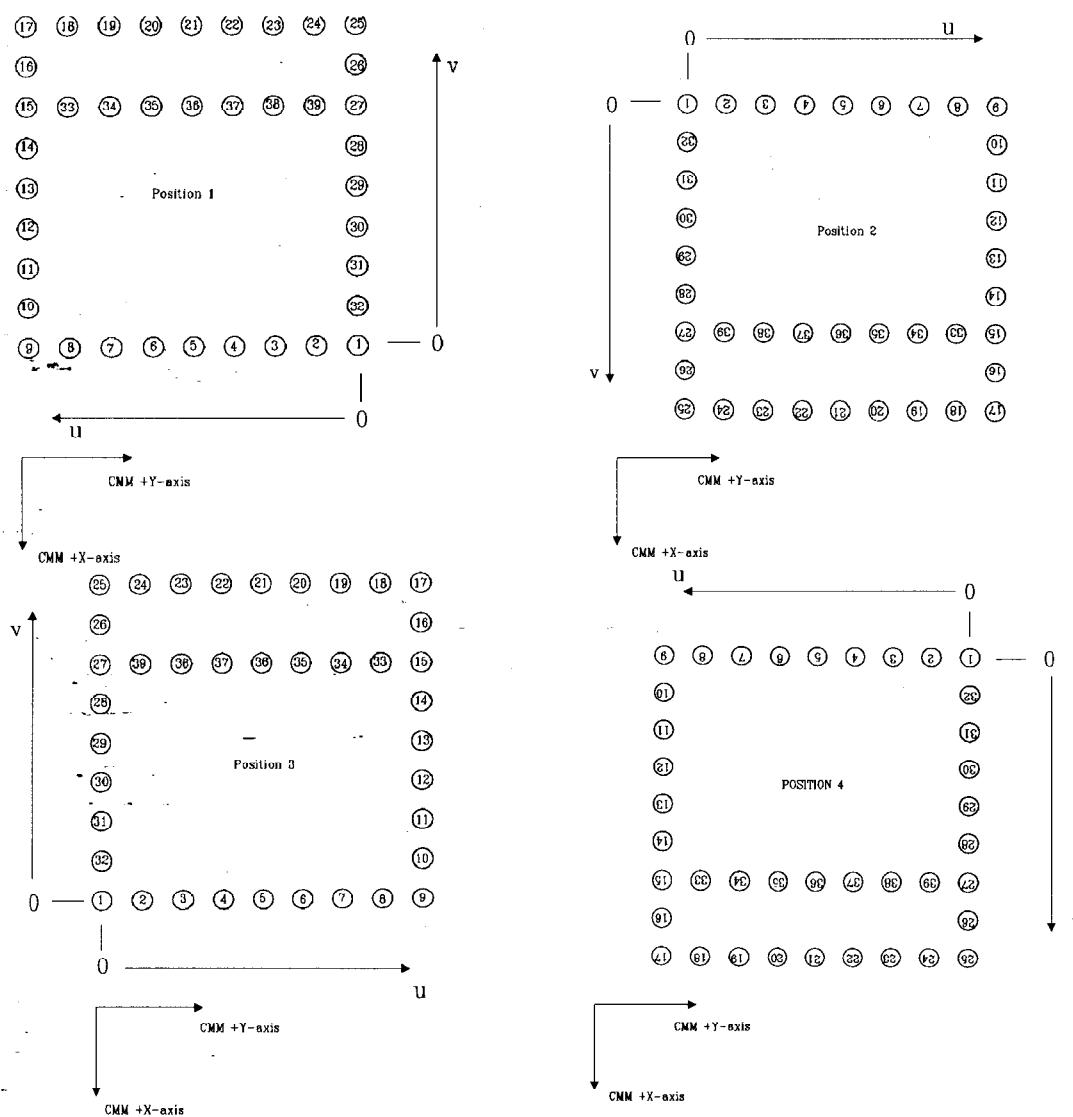

Figure 1: The four plate positions used for the swing round measurement procedure

Calibration plate coordinate results (5-14-92)

These are the 2-dimensional values for the center circles projected into the symmetry plane (middle) of the plate. These are the values from the swing round method. Temperatur compensated for 20 Celsius.

APPENDIX C

Calibration plate for MITUTOYO CMM

- 1.) Measure holes in the middle of the plate (eyeballing) as 2 circles with 4 probings each (probings always along coordinate system axis) -> 8 probings total. The 2 circles should be measured ~ 1 mm vertically separated. Evaluate as a cylinder. Intersect its axis with the symmetry plane parallel to the plate's top surface through the center of the plate (offset by half of the plate's thickness)
- 2.) Always measure in the sequence 1 - 32 clockwise and counterclockwise 32 - 1. Skip holes 33 - 39
- 3.) Pay close attention to the setup sheet from the PTB. The holes between the positions have to be lined up (more or less). Make sure the plate's u-axis is oriented as indicated. For position 31 and 32 line up edge with holes 5 and 21 from position 21 (22).
