## **1. ABSTRACT**

In December 1991 the Survey and Alignment team of the Stanford Linear Accelerator Center (SLAC) purchased a Chesapeake single beam laser tracker. This paper will discuss first experiences and applications with this new type of an alignment instrument.

## **2. INTRODUCTION**

The Chesapeake Laser Systems Coordinate Measurement System (CMS) 3000 (Figure 1) is a servo controlled tracking laser interferometer measurement tool. The tracker follows a retro target while giving real time coordinate information of the retro center location. The coordinates are given in a spherical coordinate system where the distance is measured by the interferometer and the horizontal and vertical angles are determined by rotary encoders. The system is powered by a remote power supply which can be located up to 50 feet away. Into the power supply is a weather station incorporated which allows the measurement of air pressure and humidity. The temperature is measured at the tracker unit. The system computer is a COMPAQ 486/33 which communicates with the tracker unit via a Tracker Interface Board (TIB) designed by Chesapeake. The laser is a class 2 Helium Neon Laser. The instrument meets the requirements of the Food and Drug Administration, Center for Devices and Radiological Health, Federal Register 21 CFR parts 1000 and 1040 [1].

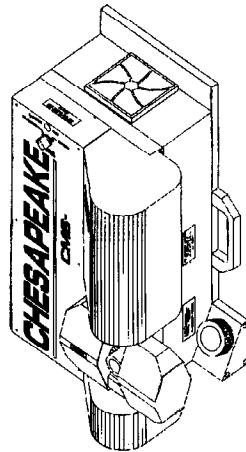

Fig 1: The CMS-3000

There are many different applications where tracking interferometry can enhance and in many ways revolutionize the conventional methods currently employed. Some of the applications include:

- Robot calibration and dynamic mapping
- Machine tool volumetric calibration
- Large assembly inspection
- Part digitization and profiling
- Reverse engineering applications
- Alignment measurements

Figure 2 represents a compressed list of the system specifications.

SYSTEM SPECIFICATIONS	
CMS-3000 Tracker Head:	Width: 12.5" Height: 23.0" Depth: 7.5" min, 9.2" max Weight: 80.0 lbs
Remote Power Unit (RPU):	Width: 9.5" Height: 12.0" Depth: 17.0" Weight: 25 lbs
Typical Tooling Stand:	Weight: 204 lbs
Assembly Floor Load:	Average = 37.5 lbs/sq. ft
Repeatability:	At least 5 ppm of measurement
Resolution:	Angular = 1 arc-second per angular unit Radial = from 0.5 to 5 microns per distance unit
Velocity:	From 1 to 6 meters/sec.
Acceleration:	> 2 g's
Distance Range:	0.17 meters (min.) to 30 meters (max.)
Elevation Range:	± 55 degrees
Azimuth Range:	>270 degrees

Fig 2: System specifications of the CMS-3000

### 3. CONCEPT OF OPERATION

Tracking interferometry is a technology which utilizes the accuracy of laser interferometry with the flexibility of automated tracking. The instrument gathers target position information in a three dimensional spherical coordinate system. In this format, the range to the target is measured with a laser interferometer which is locked onto the target's optical center by a servo feedback system. The servo motors drive the interferometer's steering optics to keep in step with the target motion. This enables the interferometer to keep a continuous return beam from the target for an uninterrupted fringe count which determines the target range within the resolution of a wavelength of red light ( $0.6238 \mu\text{m}$ ). The angular information is monitored by laser rotary encoders which are affixed to each servo axis for azimuth and elevation position in arc second resolution. The output information is converted to rectangular X, Y, Z format in a user defined coordinate system [1,3].

Tracking interferometry differs from conventional measurement techniques such as theodolites in that its strength is in the range information along the beam. The greatest strength in conventional theodolite measurement is in the angular information. Typically, the best geometry for the greatest accuracy in theodolite use is in a set up which enhances the measurement area by using as much angular information as possible and therefore increases the redundancy of the data set. The idea is similar with trackers as we increase the redundancy by introducing a highly accurate range information with each measurement.

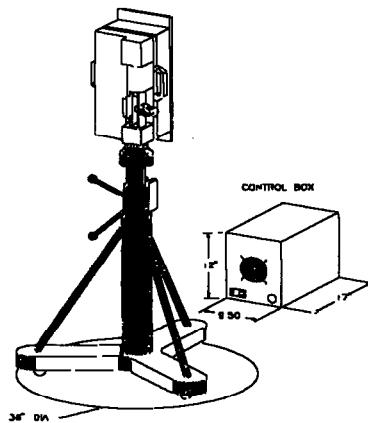

Fig 3: CMS-3000 on a tooling stand with power supply

#### **4. CALIBRATION AND SETUP CONSIDERATIONS**

After the system has been powered up and stabilized (approximately 30 min.), a local scaling procedure should be done. This can be done by placing the reflector in the TMR (Tracker Mount Reset) from which we know the distance to the center of the tracker or by measuring a scale bar. This establishes the true initial distance from the target center to the tracker. The TMR reset procedure has to be re-executed should a beam interruption occur.

Before each measurement set a field calibration should be performed. Part of the tracker system is a calibration dome with 16 mounted reflectors and 16 mirrors. These 32 targets are spread over the complete measurement range of the tracker unit. The tracker in its calibration mode will measure unattended all the targets of the dome in direct and reverse measurements. The calibration software will then calculate 12 independent parameters of a mathematical model which compensates for various tracker errors. This approach is similar to the determination of theodolite axis errors only that a tracker model has to allow for more additional degrees of freedom than a theodolite. These errors have to be seen as unavoidable deviations from a perfect assembly. Once these parameters are determined they serve as filters for the measurement data.

Initially, the tracker was not stable enough for the calibration parameters to remain approximately the same between calibrations. After the problem was discovered and fixed, the parameters stay in general the same to within 10 % change. From calibration to calibration the tracker was carted around and handled like we would expect it to be handled in the field. To date a calibration takes still about 2 hours and can not be executed completely unattended. We believe that the calibration time will be reduced to less than an hour and we anticipate a complete unattended calibration procedure in the near future.

A typical measurement session has an error budget. In each session it is attempted to hold most measurement errors to a minimum. Considerations for error sources for the system include:

- Target offset error
- Target nest repeatability
- Local environment characteristics
- Physical changes of the stand or measured object.
- Atmospheric conditions and their changes.

#### **5. MEASUREMENTS AND RESULTS**

##### **5.1. TEST NETWORK**

For the testing of the laser tracker a network was established, with its configuration similar to the conditions we will encounter for its intended use during the FFTB (Final Focus Test Beam) survey. As a test site we chose our calibration laboratory. The survey calibration laboratory is an underground chamber approximately 5 x 30 meters, located at sector 10 of the LINAC (LINear ACcelerator) and at the same level as the accelerator. The atmospheric conditions of this laboratory are very stable e.g. the temperature is stable to within 1°C. The targets are reflector cups bolted to the walls and to the floor. The targets are distributed evenly horizontally and vertically along the chamber.

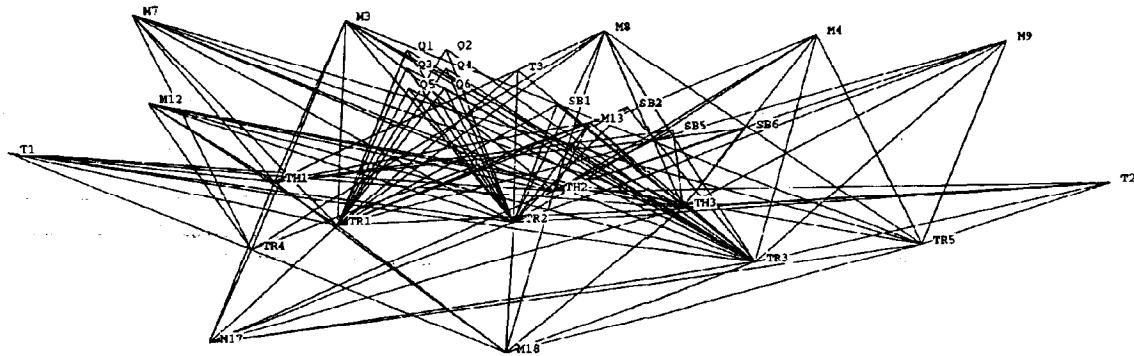

Fig 4: Network configuration sector 10. Plan view.

## 5.2. BUNDLE ADJUSTMENT

Part of our SIMS (SLAC Industrial Measurement System) is a rigorous bundle adjustment. Its major strength is that we don't assume the measurement stations to be leveled. The measurement stations are defined by three coordinates and three orientation angles with respect to the network reference system. This feature is a requirement for laser tracker measurements as there is no mechanical way to link the tracker stations orientation to the gravity vector. We also expanded this adjustment to allow for additional observation types like the distance information from the interferometer and elevation or leveled height differences between targets. All the observations are input for the rigorous least square adjustment package which calculates the X, Y and Z positions and the three rotations of the measurement stations as well as the positions of the targets. The output includes statistical information which allows us to predict the reliability of the calculated results as a function of the geometry and quality of the measurements. The SIMS bundle adjustment is the only available package to incorporate 4 types of observations which are directions, distances between points (e.g. scale bars), radial distances and leveled height differences.

Furthermore we introduced an additional parameter for each station. This unknown represents a constant distance offset. The tracker distance has to be set initially by placing the reflector into the TMR (Tracker Mount Reset). This reset depends on the calibrated distance value stored for the position of the cup as well as the quality of the positioning (e.g. dust particles). We are interested in error ellipses of less than 0.1 mm. Because of this goal we chose not to assume this initial distance to be accurate enough and rather treat it as an additional unknown. The calculation of the parameter is optional. The introduction of these additional parameters might introduce some unwanted correlation between the parameters. Simulations showed an improvement of the model, the calculated parameters appear to be significant and independent. Although computer simulations indicate good results the tracker field test represents its real test.

## 5.3. DATA SETS

All measurements were done over a time period of one week. The accuracy for the observations for all data sets was assumed as follows:

Directions tracker	0.0015 [gon]
Directions theodolite	0.0005 [gon]
Distances	0.015 [mm]
Height differences	0.050 [mm]

All observations were done in direct and reverse mode. The table below shows the differences between the direct and reverse observations for the station #2. A complete comparison is listed in Appendix A.

Point	AZ Diff. Direct - Reverse (GCRN)	V Diff. Direct - Reverse (GCRN)	Dist. Diff. Direct - Reverse (μm)
M3	0.0004	0.0098	1
M4	0.0074	0.0108	-2
M7	0.0037	0.0093	-6
M8	0.0097	0.0028	-6
M12	0.0058	0.0078	-6
M13	0.0108	0.0068	5
M17	0.0070	0.0051	-1
M18	0.0066	0.0109	-6

The following tables show the results associated with the eight targets observed by all the stations (with exception of tracker station #2 from where M9 couldn't be observed. The complete data sets (input and output from the bundle solution) are listed in the Appendices B - E.

### 5.3.1. 5 TRACKER STATIONS

## **5.4. RESULTS**

Initially a datum for the network had to be defined. In this case the tracker station 2 (1-2) has been chosen as the origin with its rotations being fixed to zero in order to define the three axis. Additionally two scale bars have been introduced to supply the scale for the network. The comparison of the direct and reverse measurements indicates that the angles are not comparing as well as we are used to from theodolite observations. This was to be expected since the encoders have a resolution of only 1 arc second. As a

result we weighed the tracker directions one third less as we weighed a theodolite direction. The distances in comparison show differences within the  $\mu\text{m}$  range.

When comparing the results between the introduction of the additional distance offset parameters (5.3.1. or Appendix B) and the classical approach (5.3.1.1. or Appendix C), the first observation is the remarkable stability. The output coordinates are similar, the distribution of the residuals are similar and the computed distance offsets range from  $4\mu\text{m}$  up to  $40\mu\text{m}$ . In fact the introduction of an extra unknown per station confirms that the model improves as the residuals get overall smaller. The other impact is a globally smaller standard error in Z (within  $\mu\text{m}$  range) and a higher standard error in X or Y depending on the location of the points with respect to the stations. This last observation is a direct consequence of the network geometry. The points are distributed along a line, the maximum difference in X is 12 meters versus 1.5 meters in Y. Although the gain is very small (within  $\mu\text{m}$  range), it has to be noted that initially the tracker offsets have been calibrated very accurately (better than  $40\mu\text{m}$ ) and nonetheless the introduction of these additional parameters indicate a stable condition and better results.

The introduction of leveled height differences improves our accuracy in Z even further (5.3.1.2. or Appendix D). Our attempt to improve the accuracy by introducing highly accurate directions with theodolites didn't materialize (5.3.2. or Appendix E). By splitting the data and consider either theodolites or trackers the solutions converged well with a  $\sigma_0$  (a posteriori) well below one. The target locations (magnetic target cups) though were substantially different ( $\sim 0.1$  [mm]) and appeared to have moved. It was discovered that the target cups showed wear. The steel pins of the target cups had to be replaced.

## **6. CONCLUSION**

We can conclude from these tests that we are able to achieve standard errors of less than  $40\mu\text{m}$  in X, Y and Z by using the laser tracker in combination with a highly accurate leveling system like a hydrostatic water level [2]. The introduction of leveled height differences will be essential to hold the standard errors for the elevations below  $40\mu\text{m}$ . The tracker hardware appears to be in working condition. The tracker software is still in an evolutionary stage and needs considerable improvements. At this point of time we are in the process of interfacing the Chesapeake tracker to our SIMS (SLAC Industrial Measurement System) package. We work towards a unified industrial package which allows the combined usage of theodolites, laser trackers and hydrostatic levels. This package is developed under Microsoft Windows 3.1..

Job Id : Laser Tracker Test SRV2  
 Part Id : Test Laser Tracker in Sector  
 Date : Fri, Jun-01-92  
 File : ALL5\_L.3DD  
 Run : 06-17-1992 at 14:00:01

---

5 Number of stations  
 29 Total number of object points  
 99 Number of distances  
 7 Number of height differences  
 97 Total number of angle observation pairs

Iteration Summary	X	Y	Z
-----	---	---	---
XYZ Position Corrections :	75.65091	43.92026	24.02015
XYZ Position Corrections :	1.72577	4.53974	.90425
XYZ Position Corrections :	.01300	.01028	.00975

XYZ Position Corrections : .00000 .00000 .00000

BUNDLE: Solution has converged after 4 iterations

Reference standard deviation = .71  
Degrees of freedom = 183

## Horizontal and vertical angle residuals (gons)
