Search for CP Violation in $B^0/\overline{B}^0$ Decays to $\pi^+\pi^-\pi^0$ and $K^\pm\pi^\mp\pi^0$ in Regions Dominated by the $\rho^\pm$ Resonance

The *BABAR* Collaboration

24 JuLy, 2002

Abstract

We present preliminary measurements of direct and indirect CP-violating asymmetries in the decays of neutral B mesons to $\pi^+\pi^-\pi^0$ and $K^\pm\pi^\mp\pi^0$ final states dominated by the $\rho^\pm$ resonance, using a time-dependent maximum likelihood analysis. The data sample comprises 88×10^6 $\Upsilon(4S) \to B\overline{B}$ decays (80.8 fb^{-1}) collected with the *BABAR* detector at the PEP-II asymmetric-energy B Factory at SLAC. For the CP violation parameters, we measure

$$A_{CP}^{\rho K} = 0.19 \pm 0.14 \ (\text{stat}) \ \pm 0.11 \ (\text{syst}), \qquad A_{CP}^{\rho\pi} = -0.22 \ \pm 0.08 \ (\text{stat}) \ \pm 0.07 \ (\text{syst}),$$
$$C_{\rho\pi} = 0.45 \ ^{+0.18}_{-0.19} \ (\text{stat}) \ \pm 0.09 \ (\text{syst}), \qquad S_{\rho\pi} = 0.16 \ \pm 0.25 \ (\text{stat}) \ \pm 0.07 \ (\text{syst}).$$

For the other parameters in the description of the $B^0(\overline{B}^0) \to \rho\pi$ decay-time dependence, we obtain

$$\Delta C_{\rho\pi} = 0.38 \ ^{+0.19}_{-0.20} \ (\text{stat}) \ \pm 0.11 \ (\text{syst}), \qquad \Delta S_{\rho\pi} = 0.15 \ \pm 0.26 \ (\text{stat}) \ \pm 0.05 \ (\text{syst}).$$

1   Introduction

In the Standard Model, *CP*-violating effects arise from a single complex phase in the three-generation CKM quark-mixing matrix [1]. One of the central questions in particle physics is whether this mechanism is sufficient to explain the pattern of *CP* violation observed in nature. Recent measurements of the parameter $\sin 2\beta$ by the *BABAR* [2, 3] and Belle [4, 5] Collaborations establish that *CP* symmetry is violated in the neutral *B*-meson system. In addition, these two experiments have studied *CP*-violating asymmetries in *B* decays to the charmless two-body final states $K^+\pi^-$ and $\pi^+\pi^-$ [6, 7]. The time-dependent asymmetry in $\pi^+\pi^-$ is related to the angle α of the unitarity triangle.

In this paper, we investigate *CP* violation using charmless $B^0/\overline{B}^0$ decays to $\pi^+\pi^-\pi^0$ and $K^\mp\pi^\pm\pi^0$ dominated by the $\rho^\pm h^\mp$ intermediate state, where $h = \pi$ or K. As in the case of $\pi^+\pi^-$, the $\rho\pi$ mode provides a probe of both direct *CP* violation and *CP* violation in the interference between mixing and decay amplitudes. The latter type of *CP* violation is related to the angle α. In contrast to $\pi^+\pi^-$, $\rho^\pm\pi^\mp$ is not a *CP* eigenstate and four configurations $(B^0(\overline{B}^0) \to \rho^\pm\pi^\mp)$ have to be considered. Although this leads to a more complex analysis [8], it benefits from a higher branching fraction $(20 - 30 \times 10^{-6})$ [9, 10].

The ρ resonance is broad (150 MeV/c^2) and the $\rho^\pm\pi^\mp$ state may receive contributions at the amplitude level from other decay channels (*e.g.*, $B^0 \to \rho'^+\pi^-$). For this analysis, we restrict ourselves to the two regions of the $h^\pm\pi^\mp\pi^0$ Dalitz plot dominated by ρh and assign a label, ρ^+h^- or ρ^-h^+, to each event depending on the kinematics of the $h^\pm\pi^\mp\pi^0$ final state. In the following, we will use the ρ^+h^- or ρ^-h^+ labels with the above meaning.

Defining $\Delta t = t_{\rho h} - t_{\text{tag}}$ as the time interval between the decay of $B^0_{\rho h}$ and that of the other B^0 meson in the event, B^0_{tag}, the decay rate distributions can be written as [11]

$$
f^{\rho^\pm h^\mp}_{B^0\text{tag}}(\Delta t) = (1 \pm A^{\rho h}_{CP}) \frac{e^{-|\Delta t|/\tau}}{4\tau} \left[1 + \left((S_{\rho h} \pm \Delta S_{\rho h}) \sin(\Delta m_d \Delta t) - (C_{\rho h} \pm \Delta C_{\rho h}) \cos(\Delta m_d \Delta t) \right) \right],
$$
$$
f^{\rho^\pm h^\mp}_{\overline{B}^0\text{tag}}(\Delta t) = (1 \pm A^{\rho h}_{CP}) \frac{e^{-|\Delta t|/\tau}}{4\tau} \left[1 - \left((S_{\rho h} \pm \Delta S_{\rho h}) \sin(\Delta m_d \Delta t) - (C_{\rho h} \pm \Delta C_{\rho h}) \cos(\Delta m_d \Delta t) \right) \right].
$$

$$(1)$$

The time-integrated charge asymmetries $A^{\rho\pi}_{CP}$ and $A^{\rho K}_{CP}$ measure direct *CP* violation. The time dependence is described by four additional parameters. In the case of the self-tagging ρK mode, the values of these four parameters are known to be $C_{\rho K} = 0$, $\Delta C_{\rho K} = -1$, $S_{\rho K} = 0$, and $\Delta S_{\rho K} = 0$. For the $\rho\pi$ mode, they allow us to probe *CP* violation. Summing over the ρ charge in Eq. 1, and neglecting the charge asymmetry $A^{\rho\pi}_{CP}$, one obtains the simplified *CP* asymmetry between the number of B^0 and $\overline{B}^0$ tags, given by

$$
A_{B^0/\overline{B}^0} = (N_{B^0} - N_{\overline{B}^0})/(N_{B^0} + N_{\overline{B}^0}) \sim S_{\rho\pi} \sin(\Delta m_d \Delta t) - C_{\rho\pi} \cos(\Delta m_d \Delta t) . \tag{2}
$$

The parameter $C_{\rho\pi}$ describes the time-dependent direct *CP* violation and $S_{\rho\pi}$ measures *CP* violation in the interference between mixing and decay related to the angle α.

The parameters $\Delta C_{\rho\pi}$ and $\Delta S_{\rho\pi}$ are insensitive to *CP* violation. The asymmetry between $N(B^0_{\rho\pi} \to \rho^+\pi^-) + N(\overline{B}^0_{\rho\pi} \to \rho^-\pi^+)$ and $N(B^0_{\rho\pi} \to \rho^-\pi^+) + N(\overline{B}^0_{\rho\pi} \to \rho^+\pi^-)$ is described by $\Delta C_{\rho\pi}$, while $\Delta S_{\rho\pi}$ is sensitive to the strong phase difference between the amplitudes contributing to $B^0 \to \rho\pi$ decays. The naive factorization model [8] predicts $\Delta C_{\rho\pi} \sim 0.4$ while there is no prediction for $\Delta S_{\rho\pi}$.

The measurements of the six parameters $A_{CP}^{\rho K}$, $A_{CP}^{\rho\pi}$, $C_{\rho\pi}$, $\Delta C_{\rho\pi}$, $S_{\rho\pi}$, and $\Delta S_{\rho\pi}$ reported here are performed using events collected by the *BABAR* detector at the PEP-II asymmetric-energy B Factory between January 2000 and June 2002. This sample corresponds to an integrated luminosity of 80.8 fb^{-1} taken at the $\Upsilon(4S)$ resonance ("on-resonance"), which represents 88 million $B\overline{B}$ pairs, and 9.6 fb^{-1} taken around 40 MeV below the resonance ("off-resonance").

We extract the yields and *CP* parameters using a time-dependent maximum likelihood analysis based on Eq. 1. This paper is organized as follows: the *BABAR* detector is described briefly in Sec. 2. The event reconstruction and selection procedure is given in Sec. 3. B-related backgrounds and their treatment in the likelihood analysis are described in Sec. 4. The full maximum likelihood fit is discussed in Sec. 5. Finally, the results and the evaluation of systematic uncertainties are given in Secs. 6 and 7.

2   The *BABAR* Detector

A detailed description of the *BABAR* detector can be found in Ref. [12]. Charged particle momenta are measured in a tracking system consisting of a 5-layer double-sided silicon vertex tracker (SVT) and a 40-layer drift chamber (DCH) filled with a gas mixture based on helium and isobutane. The SVT and DCH operate within a 1.5-T superconducting solenoidal magnet. The typical decay vertex resolution is around 65 μm along the beam direction for the fully reconstructed $B_{\rho h}^0$, and around 100 to 150 μm for the partially reconstructed tagging B_{tag}^0. Photons are detected in an electromagnetic calorimeter (EMC) consisting of 6580 CsI(Tl) crystals arranged in barrel and forward end-cap sub-detectors. The π^0 mass resolution is on average 7 MeV/c^2. The flux return for the solenoid is composed of multiple layers of iron and resistive plate chambers for the identification of muons and long-lived neutral hadrons. Tracks from the signal B decay are identified as pions or kaons by the Cherenkov angle θ_{Ch} measured with a detector of internally reflected Cherenkov light (DIRC). The typical separation between pions and kaons varies from 8σ at 2 GeV/c to 2.5σ at 4 GeV/c, where σ is the average θ_{Ch} resolution. Lower momentum kaons are identified with a combination of θ_{Ch} (for momenta down to 0.7 GeV/c) and measurements of ionization energy loss, dE/dx, in the DCH and SVT.

3   The Event Selection and Reconstruction

Signal $B_{\rho h}$ candidates are reconstructed from combinations of two charged tracks and a π^0 candidate. The charged tracks are required to be inconsistent with being an electron based on dE/dx measurements, shower shape criteria in the EMC, and the ratio of shower energy and track momentum. The photons from the π^0 must have an energy greater than 50 MeV, and a lateral shower profile variable [13] between 0.01 and 0.6. The invariant mass $m(\gamma\gamma)$ of the photons must satisfy $0.11 < m(\gamma\gamma) < 0.16$ GeV/c^2. Similarly, to form a ρ candidate, the invariant mass $m(\pi^\pm\pi^0)$ of the charged track and π^0 must satisfy $0.4 < m(\pi^\pm\pi^0) < 1.3$ GeV/c^2. If both the $(\pi^+\pi^0)$ and $(\pi^-\pi^0)$ pairs satisfy this requirement, the B candidate is rejected, as the $\pi^+\pi^-\pi^0$ might result from interfering ρ's, and cannot be associated with a definite ρ charge. The track used for the ρ candidate must be inconsistent with being a kaon based on dE/dx and DIRC information. Finally, we require $|\cos\theta_\pi| > 0.25$, where θ_π is the angle between the charged pion in the rest frame of the ρ and the ρ flight direction in the rest frame of the B. We refer to the track h in ρh as the *bachelor track*. To reject two-body B-background, the invariant mass of the two charged tracks, and the invariant mass of the bachelor track and the π^0 must be less than 5.14 GeV/c^2.

Two kinematic variables, used in the maximum likelihood fit, allow discrimination of signal B candidates from fake B candidates due to random combinations of tracks and π^0 candidates. The first variable is the beam-energy substituted mass defined as

$$m_{ES} = \sqrt{(s/2 + \mathbf{p}_i \cdot \mathbf{p}_B)^2/E_i^2 - \mathbf{p}_B^2}, \tag{3}$$

where s is the square of the center-of-mass (CM) energy, E_i and $\mathbf{p}_i$ are the total energy and three-momentum of the e^+e^- state in the laboratory frame, and $\mathbf{p}_B$ is the three-momentum of the B candidate in the same frame. Signal events populate the m_{ES} region around the B mass with a peak resolution of around $2.6 \,\mathrm{MeV}/c^2$. Candidates are required to satisfy $5.23 < m_{ES} < 5.29$ GeV/c^2. The second variable, $\Delta E = E_B^* - \sqrt{s}/2$, is the difference between the reconstructed energy of the $B_{\rho h}$ candidate in the CM frame and the beam energy. The ΔE distribution for signal events with a pion bachelor track ($\rho\pi$) peaks around zero, while the distribution for ρK signal events with the π mass hypothesis assigned to the true kaon track, is shifted by -45 MeV on average (the exact shift depends on the momentum of the kaon). Backgrounds from other decay modes of the B peak at different ΔE depending on the number of charged and neutral particles in the decay: two-body decays, three-body decays, and four-body decays peak at positive, approximately 0, and negative ΔE, respectively. In order to reduce background from other modes, we require $-0.12 < \Delta E < 0.15$ GeV.

The time difference Δt is obtained from the measured distance between the z positions (along the beam direction) of the $B_{\rho h}^0$ and B_{tag}^0 decay vertices, and the known boost of the e^+e^- system. The vertex of the B_{tag}^0 is reconstructed from all tracks in the event except those from the $B_{\rho h}^0$, and an iterative procedure [2] is used to remove tracks with a large contribution to the vertex χ^2. An additional constraint is obtained from the three-momentum and vertex position of the $B_{\rho h}^0$ candidate, and the average e^+e^- interaction point and boost. We require $|\Delta t| < 20$ ps and $\sigma(\Delta t) < 2.5$ ps, where $\sigma(\Delta t)$ is the error on Δt estimated on a per-event basis.

Discrimination between $\rho\pi$ and ρK signal events is accomplished using the Cherenkov angle measurement from the DIRC. Therefore, only ρh candidates with bachelor track inside the geometrical acceptance of the DIRC are considered. The number of photons in the DIRC associated with the bachelor track must be greater than 5. In addition, the Cherenkov angle θ_{Ch} of the bachelor track is required to be inconsistent with the proton hypothesis. Finally, we reject events where the bachelor track is inconsistent by more than 4σ with both the pion and kaon hypotheses.

Continuum $q\bar{q}$ (where $q = u, d, s, c$) events represent the dominant background source for charmless B decays. To enhance discrimination between signal and continuum background, we use a neural network (NN) that combines four discriminating variables: two kinematic variables related to the reconstructed $\rho^\pm$ candidate, the ρ mass and $\cos\theta_\pi$, and two event shape variables, $L_0 = \sum_i p_i^*$ and $L_2 = \sum_i p_i^* \times |\cos(\theta_{T_B,i}^*)|^2$, where p_i^* is the momentum of track i belonging to the rest of the event in the CM frame and $\theta_{T_B,i}^*$ is the angle between the momentum of track i and the B thrust axis T_B in the CM frame. Optimization and training of the NN is performed using off-resonance data contained in the signal region, to reduce residual correlations of the NN with the kinematic variables used in the maximum likelihood fit. In addition, the Monte Carlo signal training sample, generated with a GEANT4-based Monte Carlo simulation [14], only consists of correctly reconstructed signal events to increase the discrimination against cross-feed from other decay modes of the B. The distributions of the NN output for correctly reconstructed $\rho\pi$ events, $\rho\pi$ events with a misreconstructed π^0, and continuum background are shown in Fig. 1. A cut is applied on the NN output at 0.54 in order to reduce the number of continuum events entering the likelihood analysis. In addition, the NN output is used as a discriminating variable in the likelihood. Approximately
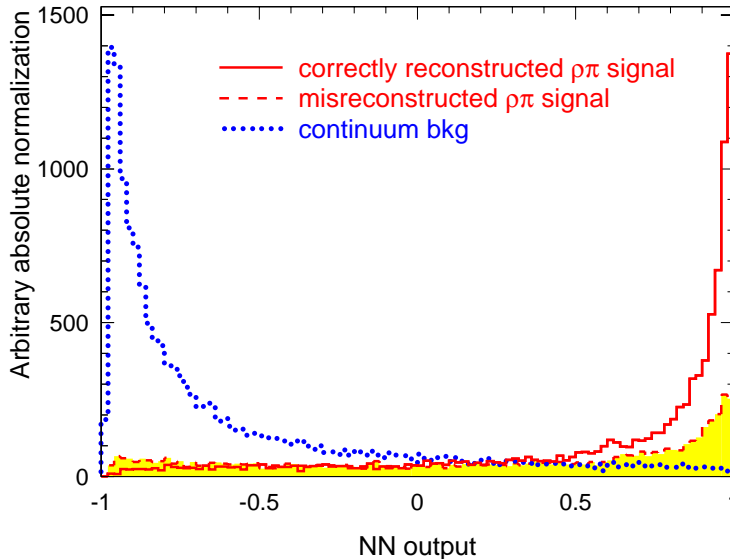

Figure 1: Distributions of the NN output for correctly reconstructed $\rho\pi$ signal, misreconstructed $\rho\pi$ signal and continuum background.

37% of the events have more than one candidate passing this selection. In this case, we choose the candidate with the reconstructed π^0 invariant mass closest to the nominal π^0 mass [15].

After all selection criteria have been applied, a total of 21172 events enter the likelihood fit. For 86% of the neutral B decays to $\rho^{\pm}\pi^{\mp}$ that pass the event selection, the charge of the ρ is unambiguously determined by the charge of the slowest track. If the lower-momentum track has a momentum below 2.4 GeV/c, its charge is assigned to the ρ. This approach does not rely on the reconstruction of the π^0, and hence provides a more robust way to assign the charge to the ρ than criteria based on the reconstructed mass of ρ candidates. For the remaining events, the sign of the ρ is that of the $\pi^{\pm}\pi^0$ combination with invariant mass closest to the ρ mass [15]. With this procedure, only 5% of the events are assigned an incorrect charge.

To determine the flavor of the B^0_{tag} meson we use the same B-tagging algorithm used in the *BABAR* $\sin 2\beta$ analysis [2]. The algorithm relies on the correlation between the flavor of the b quark and the charge of the remaining tracks in the event after removal of the tracks from the $B \to \rho h$ candidate. We define five mutually exclusive tagging categories: `Lepton`, `Kaon`, `NT1`, `NT2`, and `Untagged`. `Lepton` tags rely on primary electrons and muons from semileptonic B decays, while `Kaon` tags exploit the correlation in the process $b \to c \to s$ between the net kaon charge and the charge of the b quark. The `NT1` (more certain tags) and `NT2` (less certain tags) categories are derived from a neural network that is sensitive to charge correlations between the parent B and unidentified leptons and kaons, soft pions, or the charge and momentum of the track with the highest CM momentum. The addition of `Untagged` events provides a larger sample for measuring the charge asymmetries $A_{CP}^{\rho K}$ and $A_{CP}^{\rho \pi}$.

The quality of tagging is expressed in terms of the effective efficiency $Q = \sum_c \epsilon_c \langle D_c \rangle^2$, where ϵ_c is the fraction of events tagged in category c and the dilution $\langle D_c \rangle = 1 - 2 \langle w_c \rangle$ is related to the average mistag fraction $\langle w_c \rangle$. The mistag fraction $\langle w_c \rangle$, the efficiency ϵ_c, and the mistag difference $\Delta w_c = w_c - \overline{w}_c$, where $w_c, \overline{w}_c$ are the mistag probabilities for B^0 and $\bar{B}^0$, are measured for each tagging category c with a large data sample of fully reconstructed neutral B decays to

Table 1: Tagging efficiency ϵ_c, average dilution $\langle D_c \rangle = 1 - 2 \langle w_c \rangle$, dilution difference $\Delta D_c = -2\Delta w_c$, and effective tagging efficiency Q_c for signal events in each tagging category. The values are measured with fully reconstructed neutral B decays.

Category	ϵ_c (%)	$\langle D_c \rangle$ (%)	ΔD_c (%)	Q_c (%)
Lepton	10.7 ± 0.2	83.8 ± 1.6	-0.4 ± 2.4	7.5 ± 0.3
Kaon	34.8 ± 0.3	66.0 ± 1.2	3.6 ± 1.6	15.1 ± 0.5
NT1	7.7 ± 0.2	58.4 ± 2.4	-1.4 ± 3.6	2.6 ± 0.2
NT2	14.1 ± 0.2	25.4 ± 2.0	7.2 ± 3.0	0.9 ± 0.2
Untagged	32.7 ± 0.4	$-$	$-$	$-$
Total Q				26.2 ± 0.7

$D^{(*)-}x^+$ ($x^+ = \pi^+, \rho^+, a_1^+$) and $J/\psi K^{*0}$ ($K^{*0} \rightarrow K^+\pi^-$) flavor eigenstates [2]. The tagging quality factor Q is found to be $(26.2 \pm 0.7)\%$ (see Table 1). We use these measurements of the tagging efficiencies and dilutions for $\rho\pi$ and ρK signal, and we float separate continuum background event yields for each category in the maximum likelihood fit.

4 B-related Backgrounds

We use a Monte Carlo simulation to study the potential cross-feed from other charm and charmless B decays starting from a list of more than 80 charmless decay modes to two-body, three-body and four-body final states, and an inclusive Monte Carlo simulation of $B \rightarrow$ charm decays. We estimate the number of events passing the event selection criteria using the selection efficiency from Monte Carlo and either measured branching ratios [16] or upper limits where available, or estimates based on related measured decay modes. We identify the 20 charmless modes that have more than one event entering the final sample.

These modes are grouped into seven classes for which the discriminating variables have similar distributions. For each of the seven classes, a correction term is introduced in the likelihood, with a fixed number of events. Two additional classes for $B^+ \rightarrow$ charm and $B^0 \rightarrow$ charm decays are also included in the B-background model, which is summarized in Table 2.

Like the selection efficiencies, the shapes of the distributions of the discriminating variables are obtained from Monte Carlo simulations. Figure 2 shows the ΔE-m_{ES} planes for three main B-related backgrounds: $B^+ \rightarrow \rho^0\pi^+$, $B^0 \rightarrow \rho^+\rho^-$, and $B \rightarrow$ charm. The charmless B-background NN output and m_{ES} distributions are signal-like, and the ΔE variable discriminates between two-body ($\Delta E > 0$), three-body (ΔE peaking around 0) and four-body ($\Delta E < 0$) modes. The m_{ES} and ΔE distributions for $B \rightarrow$ charm background have shapes similar to the continuum distributions.

For charged B-backgrounds, the Δt distribution is modeled as

$$g^{\rho^{\pm}h}_{B^0_{\text{tag},c}}(\Delta t) = \frac{1}{4\tau}\left[1 \pm A_h(1 - 2w_c^{\pm})\right]e^{-|\Delta t|/\tau},$$

$$g^{\rho^{\pm}h}_{\bar{B}^0_{\text{tag},c}}(\Delta t) = \frac{1}{4\tau}\left[1 \mp A_h(1 - 2w_c^{\pm})\right]e^{-|\Delta t|/\tau}, \tag{4}$$

where A_h is the asymmetry between the number of ρ^+h^- and ρ^-h^+ candidates for a given flavor tag and is extracted from Monte Carlo, and $w_c^{\pm}$ is the mistag fraction for tagging category c, measured

in data using a sample of fully reconstructed charged B decays to $D^{*0}\pi^+$ for which we assume direct CP conservation.

For neutral B-backgrounds, the Δt distribution is parametrized as for signal, where $A_{CP}^h = S_h = \Delta S_h = C_h = 0$, and ΔC_h is computed from Monte Carlo to take into account possible correlations between the reconstructed ρ charge and the flavor tag. We do not model CP violation for the B-background in the nominal fit. The corresponding systematic uncertainties in our measurements are discussed in Sec. 7.

Table 2: B-background modes retained in the maximum likelihood fit, classified into nine categories. The number of expected events contributing to the $\rho\pi$ and ρK PDFs, scaled to 80.8 fb^{-1}, and integrated over the full fit region, is reported in the 2nd and 3rd columns. The 4th and 5th columns give the assumed parameter values for the Δt distributions (see text). The last column gives the branching ratio (in units of 10^{-6}) if measured, or the estimated range if not (these cases are indicated by the symbol *).

| Charged Mode	$N_{\exp}^\pi$	$N_{\exp}^K$	A_π	A_K	(Br $\pm$ error) (10^{-6})
$B^+ \to K^{*+}(K^+\pi^0)\rho^0$	0.41	2.16	1	-1	$3 - 13^*$
$B^+ \to K^{*0}(K^+\pi^-)\rho^+$	0.06	7.23	1	-1	$10 - 40^*$
$B^+ \to \rho^+\rho^0$	15.17	0	0.22	–	$10 - 20^*$
$B^+ \to \eta'(\rho^0\gamma)K^+$	0.19	7.78	1	-1	22.1 ± 2.1
$B^+ \to \eta'(\rho^0\gamma)\pi^+$	1.53	0	-1	–	$1 - 5^*$
$B^+ \to \rho^+\pi^0$	23.22	0	-1	–	$7 - 23^*$
$B^+ \to \rho^0 K^+$	2.05	21.20	0.80	-1	8.4 ± 4.0
$B^+ \to \rho^0\pi^+$	36.51	0	-0.46	–	9.7 ± 3.2
$B^+ \to K_S^0\pi^+$	8.24	0	-0.76	–	8.7 ± 1.3
$B^+ \to K^+ f_0(\pi^+\pi^-)$	1.69	15.46	1	-1	11.7 ± 4.0
$B^+ \to K^+\pi^0$	0.17	13.50	0	-1	11.6 ± 1.5
$B^+ \to \pi^+\pi^0$	5.09	0	-1	0	5.9 ± 1.4
$B^+ \to$ charm	195.0	31.8	0	-0.46	
Neutral Mode	$N_{\exp}^\pi$	$N_{\exp}^K$	ΔC_π	ΔC_K	(Br $\pm$ error) (10^{-6})
$B^0 \to K^{*+}(K_S^0\pi^+)\pi^-$	3.38	0	1	–	8.7 ± 3.0
$B^0 \to K^{*+}(K^+\pi^0)\rho^-$	0.72	5.57	1	-1	$0 - 20^*$
$B^0 \to \rho^+\rho^-$	87.64	0	0	–	$40 - 100^*$
$B^0 \to \rho^0\rho^0$	1.03	0	0	–	$0 - 3^*$
$B^0 \to a_1^+(\rho^0\pi^+)\pi^-$	9.43	0	0	–	$28 - 48^*$
$B^0 \to K^{*0}(K^+\pi^-)\pi^0$	0	6.62	–	-1	$0 - 6^*$
$B^0 \to K^{*+}(K^+\pi^0)\pi^-$	20.92	12.97	0.85	-1	8.7 ± 3.0
$B^0 \to K^+\pi^-$	1.87	2.17	1	-1	18.5 ± 1.0
$B^0 \to$ charm	121.7	13.7	0	0	
Figure 2: ΔE-m_{ES} plane for three B-related backgrounds (Monte Carlo simulation): $B^+ \to \rho^0\pi^+$, $B^0 \to \rho^+\rho^-$ and $B \to$ charm. The lines indicate the cut on ΔE applied in the analysis; we require $-0.12 < \Delta E < 0.15$ GeV. It removes most of the four-body B-background modes (such as $B^0 \to \rho^+\rho^-$) and $B \to$ charm modes.

5 The Maximum Likelihood Fit

5.1 The Likelihood

The yields and the other CP and non-CP observables are determined by minimizing the quantity $-2\ln\mathcal{L}$, where $\mathcal{L}$ is the total extended likelihood defined over all tagging categories c as

$$\mathcal{L} = \prod_{c=1}^{5} e^{-N_c'} \prod_{i=1}^{N_c} \mathcal{L}_{i,c} \, , \tag{5}$$

with N_c', the number of events expected in category c and $\mathcal{L}_{i,c}$ is the likelihood computed for event i.

The sample is assumed to consist of signal, continuum background and B-background components where the bachelor track can be a pion or a kaon. The variables m_{ES}, ΔE and NN output discriminate signal from background, while the Cherenkov angle θ_{Ch} and, to a lesser extent, ΔE constrain the relative amount of $\rho\pi$ and ρK. The variable Δt allows the measurement of the parameters in the description of the $B^0(\overline{B}^0) \to \rho\pi$ decay-time dependence and provides additional background rejection. The likelihood $\mathcal{L}_{i,c}$ for event i in tagging category c is the sum of the probability density functions (PDF) over all components, weighted by the expected yields for each component,

$$\mathcal{L}_{i,c} \quad = \quad N_{\rho\pi}\epsilon_c \mathcal{P}_{i,c}^{\rho\pi} + N_{\rho K}\epsilon_c \mathcal{P}_{i,c}^{\rho K} + N_{q\rho\pi}^c \mathcal{P}_{i,c}^{q\rho\pi} + N_{q\rho K}^c \mathcal{P}_{i,c}^{q\rho K} + \mathcal{L}_{i,c}^{B,\pi} + \mathcal{L}_{i,c}^{B,K} \, , \tag{6}$$

where

- $N_{\rho h}$ is the number of signal events of type ρh in the entire sample ($h = \pi, K$).

- ϵ_c is the fraction of signal events that are tagged in category c (given in Table 1).

14

- $N_{q\rho h}^c$ is the number of continuum background events with bachelor track of type h that are tagged in category c.

- $\mathcal{P}_c^{\rho h} = \mathcal{P}^{\rho h}(m_{ES}) \cdot \mathcal{P}^{\rho h}(\Delta E) \cdot \mathcal{P}^{\rho h}(\mathrm{NN}) \cdot \mathcal{P}^{\rho h}(\theta_{Ch}) \cdot \mathcal{P}_c^{\rho h}(\Delta t)$ is the PDF for signal events. $\mathcal{P}_c^{\rho h}(\Delta t)$ contains the measured physics quantities defined in Eq. 1 diluted by the effects of mistagging and the Δt resolution.

- $\mathcal{P}_{i,c}^{q\rho h}$ is the PDF for continuum background events with bachelor track of type h.

- $\mathcal{L}_c^{B,\pi}$ and $\mathcal{L}_c^{B,K}$ are the B-background contributions where the bachelor track is a true pion and a true kaon, respectively (see Sec. 4).

Due to the relatively large number of low-energy photon candidates in π^0 reconstruction, the decay $\rho^\pm\pi^\mp \to \pi^+\pi^-\pi^0$ can be misreconstructed. These misreconstructed events have different shapes than correctly reconstructed signal for the distributions of the variables m_{ES}, ΔE and NN output. Additionally, in some cases the assignment of the ρ charge may be wrong. These effects are taken into account by splitting the signal PDFs into three parts: true signal events that are correctly reconstructed, misreconstructed true signal events with right-sign charge, and misreconstructed true signal events with wrong-sign charge. The fractions of the three species of signal events are extracted from the Monte Carlo.

5.2 The Probability Density Functions

- **m_{ES}**
  The distribution for correctly reconstructed signal is parametrized using a Gaussian with a power law tail on the low side, where the mean is free to vary in the likelihood fit. The continuum background is parametrized using an ARGUS function [17] with a floating shape parameter.

- **ΔE**
  The distribution for correctly reconstructed signal is parametrized using the sum of two Gaussians, while the distributions for misreconstructed signal (both for right-sign and wrong-sign ρ charges) are modeled with simple Gaussians. The mean of the core Gaussian for the correctly reconstructed signal is floated in the maximum likelihood fit, in order to be less sensitive to the energy calibration for π^0. Continuum background is modeled by a linear function.

- **NN output**
  The NN output PDFs for correctly reconstructed and for misreconstructed signal events are determined with the Monte Carlo. A small discrepancy is observed between the NN output distributions from Monte Carlo and from a data control sample of fully reconstructed $B^0 \to D^-\rho^+$ decays, and is propagated to the systematic error. The continuum PDF for the NN output is determined with the off-resonance data.

For the above three variables, the PDFs for correctly reconstructed $B^0 \to \rho^\pm h^\mp$ decays and for misreconstructed $B^0 \to \rho^\pm h^\mp$ decays are obtained from Monte Carlo after applying all selection cuts. The parameters for the continuum PDFs are either determined from off-resonance data, or left free to vary in the final fit to the on-resonance data sample.

- **Δt**

  The resolution function for correctly reconstructed and misreconstructed signal events is a sum of three Gaussians, identical to the one described in Ref. [2], with parameters determined from a fit to a large data sample of fully reconstructed neutral B decays to $D^{(*)-}x^+$ ($x^+ = \pi^+, \rho^+, a_1^+$) and $J/\psi K^{*0}$ ($K^{*0} \to K^+\pi^-$). The continuum Δt distribution is parametrized using a triple Gaussian with a common mean and three distinct widths that scale the Δt per-event error. The six parameters describing the shape of the the Δt continuum PDF are free to vary in the maximum likelihood fit. For each tagging category and bachelor hypothesis (π or K), a parameter similar to A_h for B-related backgrounds (see Sec. 4) is introduced to take into account the correlations between the charge of the ρ candidate and the flavor tag. The values of these parameters are determined using on-peak data.

- **Particle identification**

  The identification of the bachelor track as a pion or a kaon is accomplished with the Cherenkov angle measurement from the DIRC. We construct two Gaussian PDFs from the difference between measured and expected values of θ_{Ch} for the pion or kaon hypothesis, normalized by the resolution. The DIRC performance is parametrized using a data sample of $D^{*+} \to D^0\pi^+$, $D^0 \to K^-\pi^+$ decays. Within the statistical precision of the control sample, we find a similar response for positive and negative tracks and use a single parametrization for both.

6 Results

We find 413^{+34}_{-33} (stat) $\rho\pi$ and 147^{+22}_{-21} (stat) ρK events in our data sample and we measure the CP parameters

$$A_{CP}^{\rho K} = 0.19 \pm 0.14 \text{ (stat)}, \qquad A_{CP}^{\rho\pi} = -0.22 \pm 0.08 \text{ (stat)},$$
$$C_{\rho\pi} = 0.45^{+0.18}_{-0.19} \text{ (stat)}, \qquad S_{\rho\pi} = 0.16 \pm 0.25 \text{ (stat)}. \tag{7}$$

The two other observables in the decay rates (Eq. 1) are measured to be

$$\Delta C_{\rho\pi} = 0.38^{+0.19}_{-0.20} \text{ (stat)}, \qquad \Delta S_{\rho\pi} = 0.15 \pm 0.26 \text{ (stat)}. \tag{8}$$

The correlations between these parameters are summarized in Table 3.

Alternatively, the results on direct CP violation can be expressed using the asymmetries

$$A_{+-} = \frac{N(\overline{B}^0_{\rho\pi} \to \rho^+\pi^-) - N(B^0_{\rho\pi} \to \rho^-\pi^+)}{N(\overline{B}^0_{\rho\pi} \to \rho^+\pi^-) + N(B^0_{\rho\pi} \to \rho^-\pi^+)} = \frac{A_{CP}^{\rho\pi} - C_{\rho\pi} - A_{CP}^{\rho\pi} \cdot \Delta C_{\rho\pi}}{1 - \Delta C_{\rho\pi} - A_{CP}^{\rho\pi} \cdot C_{\rho\pi}}, \tag{9}$$

$$A_{-+} = \frac{N(\overline{B}^0_{\rho\pi} \to \rho^-\pi^+) - N(B^0_{\rho\pi} \to \rho^+\pi^-)}{N(\overline{B}^0_{\rho\pi} \to \rho^-\pi^+) + N(B^0_{\rho\pi} \to \rho^+\pi^-)} = -\frac{A_{CP}^{\rho\pi} + C_{\rho\pi} + A_{CP}^{\rho\pi} \cdot \Delta C_{\rho\pi}}{1 + \Delta C_{\rho\pi} + A_{CP}^{\rho\pi} \cdot C_{\rho\pi}}. \tag{10}$$

In the decays $\overline{B}^0_{\rho\pi} \to \rho^+\pi^-$ and $B^0_{\rho\pi} \to \rho^-\pi^+$ the spectator quark is involved in the formation of the ρ meson. These two decay modes are related to the direct CP asymmetry A_{+-} according to Eq. 9. Similarly in Eq. 10, we probe direct CP violation through the asymmetry A_{-+} using the decays $\overline{B}^0_{\rho\pi} \to \rho^-\pi^+$ and $B^0_{\rho\pi} \to \rho^+\pi^-$. In this case the π meson is formed from the spectator quark. From the above fitted values (Eq. 7 and Eq. 8) and their correlation matrix (Table 3) we obtain

$$A_{+-} = -0.82 \pm 0.31 \text{ (stat)}, \qquad A_{-+} = -0.11 \pm 0.16 \text{ (stat)}.$$

Table 3: Correlation coefficients (in percent) between the six parameters $A_{CP}^{\rho K}$, $A_{CP}^{\rho\pi}$, $C_{\rho\pi}$, $\Delta C_{\rho\pi}$, $S_{\rho\pi}$ and $\Delta S_{\rho\pi}$ obtained for a data sample of 88 million $B\overline{B}$ pairs. The global correlation coefficient is the largest correlation between the parameter in question and any linear combination of the other 28 free parameters in the likelihood fit.

	Global correlation	$A_{CP}^{\rho\pi}$	$A_{CP}^{\rho K}$	$C_{\rho\pi}$	$\Delta C_{\rho\pi}$	$S_{\rho\pi}$	$\Delta S_{\rho\pi}$
$A_{CP}^{\rho\pi}$	15.6	100	3.4	-11.8	-10.4	0.6	0.5
$A_{CP}^{\rho k}$	6.3	3.4	100	-1.3	-1.1	-0.4	-0.5
C	28.8	-11.8	-1.3	100	23.9	9.2	-6.8
ΔC	28.3	-10.4	-1.1	23.9	100	6.9	-9.2
S	24.9	0.6	-0.4	9.2	6.9	100	-23.4
ΔS	25.1	0.5	-0.5	-6.8	-9.2	-23.4	100

Figure 3 shows the distributions of m_{ES} and ΔE for data samples that are enhanced in signal using cuts on the signal-to-continuum likelihood ratio of the other discriminating variables. Figures 4 and 5 show respectively the time-dependent asymmetry $A_{B^0/\overline{B}^0}$ (see Eq. 2) between B_{tag}^0 and $\overline{B}_{\text{tag}}^0$ events in the Lepton and Kaon categories, and the time-dependent asymmetry $A_{\rho^+\pi^-/\rho^-\pi^+}$ between $\rho^+\pi^-$ and $\rho^-\pi^+$ for all the tagging categories, after a cut on the signal-to-continuum likelihood ratio of all discriminating variables except Δt.

As a validation of the Δt parametrization in data, we allow τ and Δm_d to vary in the fit. We find $\tau = (1.59 \pm 0.12)\,\text{ps}$ and $\Delta m_d = (0.51 \pm 0.09)\,\text{ps}^{-1}$, and the remaining free parameters are stable with respect to the nominal fit with fixed τ and Δm_d. When allowing $\Delta C_{\rho K}$ to vary, we find $\Delta C_{\rho K} = -1.15 \pm 0.34$, which is consistent with the expected value of -1 used in the nominal fit.
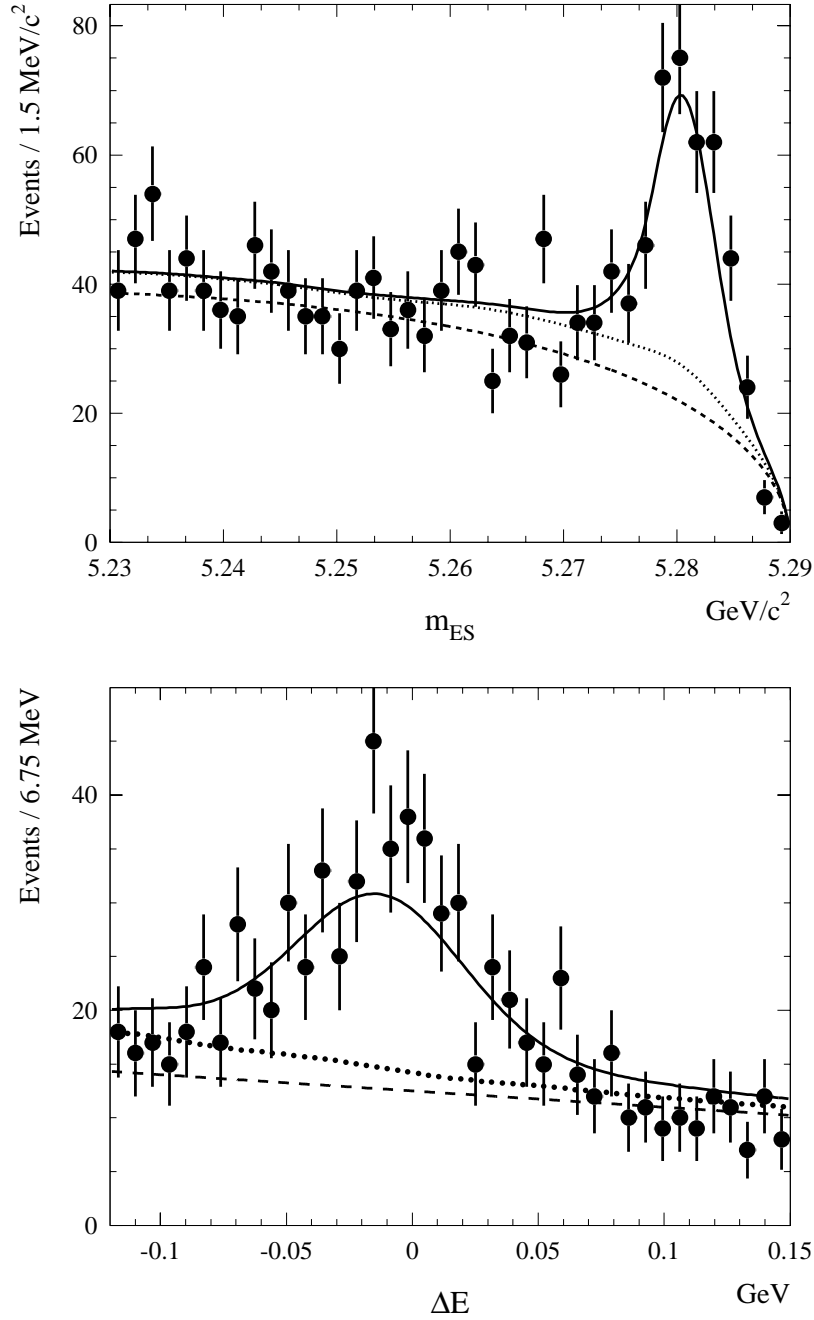

Figure 3: Distributions of m_{ES} and ΔE for samples enhanced in $\rho\pi$ signal using cuts on likelihood ratios. The solid curve represents a projection of the maximum likelihood fit result. The dashed curve represents the contribution from continuum events ($\rho\pi$ and ρK candidates combined), and the dotted line indicates the combined contributions from continuum events and B-related backgrounds, including ρK.
18

Figure 4: Time distribution and asymmetry ($A_{B^0/\overline{B}^0}$ in Eq. 2) for B^0_{tag} and $\overline{B}^0_{\text{tag}}$ decaying to $\rho\pi$, in the Lepton and Kaon categories. The sample was enriched in signal events by applying a cut on the signal-to-continuum likelihood ratio. The solid curve is a likelihood projection of the result of the full fit, and is normalized to the expected number of events according to that fit (71 signal events, 36 continuum background events and 10 B background events). The dotted line is the contribution from B-related backgrounds and the dashed line is the total B and continuum background contribution. The depression around zero in the asymmetry plot is due to the relatively large fraction of continuum events in this region of Δt. The non-zero central value for the CP parameter $S_{\rho\pi}$ induces a small contribution to the asymmetry that is odd in Δt.
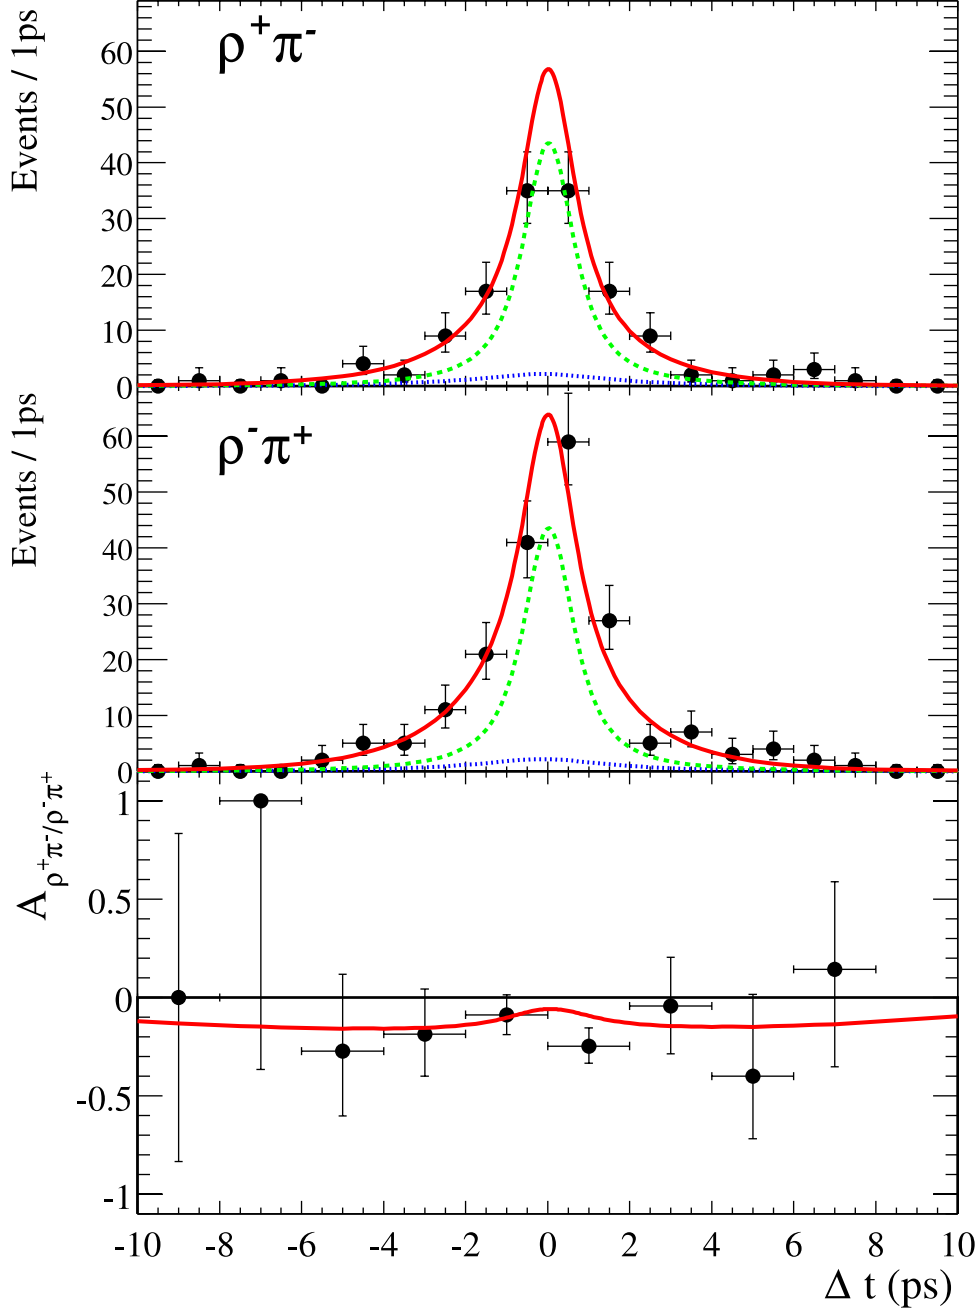

Figure 5: Time distribution and asymmetry $A_{\rho^+\pi^-/\rho^-\pi^+}$ between $\rho^+\pi^-$ and $\rho^-\pi^+$ for all the tagging categories. The sample was enriched in signal events by applying a cut on the signal-to-continuum likelihood ratio. The solid curve is a likelihood projection of the result of the full fit, and is normalized to the expected number of events according to that fit (156 signal events, 157 continuum background events and 21 B background events). The dotted line is the contribution from B-related backgrounds and the dashed line is the total B and continuum background contribution. The depression around zero in the asymmetry plot is due to continuum dilution. In the absence of continuum background, the asymmetry curve would be flat and equal to $A_{CP}^{\rho\pi}$ defined in Eq. 1.

7 Systematic Uncertainties

Several sources contribute to the systematic error on the measured observables.

- **Δm_d and B lifetime**
  This systematic error is estimated by varying the values of Δm_d and the B lifetime with respect to their world average [15] by one standard deviation.

- **Δt resolution function**
  Since the parameters of the time distribution for the continuum background are fitted in the data, the only contribution to the systematic uncertainty is due to the Δt resolution for signal. We propagate the errors on each parameter (scale factors, biases, fraction of tails) of the signal Δt resolution function to the fit results.

- **Tagging**
  We propagate the uncertainties on the tagging dilutions and the tagging efficiencies to the fit results.

- **Fraction of misreconstructed signal events and misreconstruction of ρ charge**
  Both the the fraction of misreconstructed signal events and the fraction of events with misreconstructed ρ charge and are determined with the Monte Carlo. We assign a conservative 25% uncertainty to these parameters and propagate this error to the fit results.

- **Fitting procedure**
  We perform fits on large Monte Carlo samples of a weighted mixture of $\rho\pi/\rho K$ signal, as well as fits to a large number of toy Monte Carlo samples of the same size as our data sample that contain realistic amounts of both continuum and B-related backgrounds. The small biases observed in these two tests are added in quadrature and assigned as a systematic uncertainty.

- **m_{ES}, ΔE and NN output PDFs**
  The continuum PDFs for m_{ES} and ΔE are fitted to the data in the likelihood analysis. The continuum PDF for the NN output is determined with the off-resonance data and we propagate the statistical uncertainty due to the limited size of this sample to the fit results. We evaluate the systematic uncertainties due to the signal PDFs with a large $B^0 \to D^-\rho^+$ data control sample. The small differences observed between the distribution shapes for Monte Carlo events and the distribution shapes obtained from the data control sample are used as an estimate of the systematic uncertainty on the signal PDFs. These uncertainties are propagated to the fit results.

- **Particle identification**
  We assume that the average position of the Cherenkov angle $\langle\theta_{Ch}\rangle$ is known with a precision of 0.5 mrad and that there is an uncertainty of 10% on $\sigma(\theta_{Ch})$. We propagate these conservative errors to our fit results.

- **B-related backgrounds**
  The number of events in the various modes entering our description of the B background are varied according to the error on their branching ratio, if measured, or in the range indicated in Table 2.
  The parameters (A_h and ΔC_h) describing the correlation between the tagging and the ρ charge

assignment are varied within a conservative range. For some of the major contaminations ($\rho^+\rho^-$, $\rho^0\pi^+$, and $B \to$ charm) conservative ranges are extracted from various Monte Carlo studies. For other major contaminations ($K^{*+}(K^+\pi^0)\pi^-$, $\rho^0 K$) a conservative error equal to the correction itself is used. For the other modes, the full range $[-1, +1]$ is used for the systematic study.

All B-background modes can potentially exhibit direct CP violation, and a few of them can potentially exhibit CP violation in the interference between decay and mixing. Finally, for the neutral modes, various physical phases may lead to a non-zero value of the phenomenological parameter ΔS_h. For the major contaminations listed previously, a Monte Carlo study yields the maximum possible range for the corresponding effective parameters. This range is then used for the systematic study. For the other modes, the full range $[-1, +1]$ is used.

Table 4 summarizes the various sources contributing to the systematic error on the measurements of the six parameters $A_{CP}^{\rho K}$, $A_{CP}^{\rho\pi}$, $C_{\rho\pi}$, $\Delta C_{\rho\pi}$, $S_{\rho\pi}$, and $\Delta S_{\rho\pi}$. The main source of systematic error arises from the uncertainty on the B background components. Finally, the systematic errors for the direct CP asymmetries A_{+-} and A_{-+} (see definitions in Eq. 9 and Eq. 10) are ± 0.16 and ± 0.09 respectively.

Table 4: Summary of the systematic uncertainties on the CP and non-CP observables. The individual systematic errors are added in quadrature.

Type of systematic error	$A_{CP}^{\rho K}$	$A_{CP}^{\rho\pi}$	$C_{\rho\pi}$	$\Delta C_{\rho\pi}$	$S_{\rho\pi}$	$\Delta S_{\rho\pi}$
$\Delta m \pm 0.008\,\mathrm{ps}^{-1}$	0.000	0.000	0.005	0.005	0.001	0.001

Total	0.110	0.065	0.091	0.114	0.069	0.046

8 Summary

With a data sample of 88 million $B\overline{B}$ pairs, collected between January 2000 and June 2002 by the *BABAR* detector at the PEP-II asymmetric-energy B Factory at SLAC, we find 413^{+34}_{-33} (stat) $\rho\pi$ and 147^{+22}_{-21} (stat) ρK events and we obtain the following preliminary measurements of the CP violation parameters:

$$A_{CP}^{\rho K} = 0.19 \pm 0.14 \text{ (stat)} \pm 0.11 \text{ (syst)}, \qquad A_{CP}^{\rho\pi} = -0.22 \pm 0.08 \text{ (stat)} \pm 0.07 \text{ (syst)},$$

$$C_{\rho\pi} \;=\; 0.45 \;{}^{+0.18}_{-0.19} \;\text{(stat)} \;\pm 0.09 \;\text{(syst)}, \qquad S_{\rho\pi} \;=\; 0.16 \;\pm 0.25 \;\text{(stat)} \;\pm 0.07 \;\text{(syst)},$$

and of the other parameters in the description of the $B^0(\overline{B}^0) \to \rho\pi$ decay-time dependence:

$$\Delta C_{\rho\pi} \;=\; 0.38 \;{}^{+0.19}_{-0.20} \;\text{(stat)} \;\pm 0.11 \;\text{(syst)}, \qquad \Delta S_{\rho\pi} = 0.15 \;\pm 0.26 \;\text{(stat)} \;\pm 0.05 \;\text{(syst)}.$$

For the asymmetries A_{+-} and A_{-+}, which probe direct CP violation, we measure

$$A_{+-} \;=\; -0.82 \pm 0.31 \;\text{(stat)} \;\pm 0.16 \;\text{(syst)}, \qquad A_{-+} = -0.11 \pm 0.16 \;\text{(stat)} \;\pm 0.09 \;\text{(syst)}.$$
